rising from the cathode is allowed to collect on the top of the electrolyte in a cylindrical space formed by a water-cooled crust of magnesium chloride or fluoride, whence the metal is removed by a ladle (U.S.P. 1,408,141/22).

An interesting cell in which alloys of lead with the alkaline earth metals can be produced is that devised by Mathesius (E.P. 201,447/22), which is shown in vertical section in Fig. 6. Fused chloride is electrolysed over a bath of molten lead, arrangement being made to circulate the lead cathode until it carries the required amount of discharged alkaline earth metal. The cast-iron vessel situated within a larger vessel of the same metal serves for the electrolyser proper and contains a carbon anode, C, partly immersed in the fused salt, D, whilst the fluid lead fills the part, E, of both iron vessels and is covered by a layer of fused salt. The inner vessel is provided with a horizontal plate, G, which lies slightly below the level of

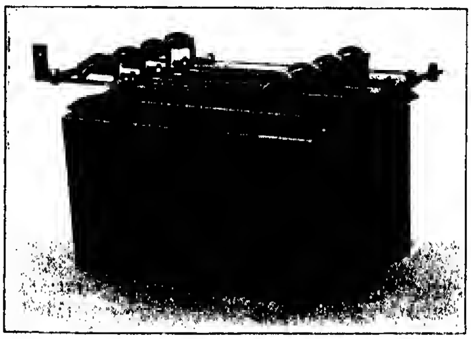

FIG. 9
Schuckert Cell

the lead and conducts the flowing metal uniformly under the surface of the anode. Openings, HH, serve for the passage of lead from the inner to the outer vessel, and an insulating ring, J, of fireclay serves to support the collecting hood, K, for chlorine. The casing, L, in the outer vessel, supports a worm and shaft which, on rotation, drives lead through a channel in N, and through P, into the inner vessel, where it flows between the anode, C, and the plate, G, receiving a fresh charge of alkali or other metal. Circulation of the lead is continued until it contains the required amount of alkaline earth metal, when it may be ladled or tapped from the outer vessel.

Amalgams of alkali or alkaline earth metals are obtained by the electrolysis of aqueous solutions, using a mercury cathode. They are useful reducing agents and their formation may be considered under mercury cells for preparing caustic soda and chlorine.

CELLS FOR THE PRODUCTION OF GASES

Oxygen, hydrogen and chlorine are often produced by electrolysis, the last named being almost entirely obtained by this method together with caustic soda.

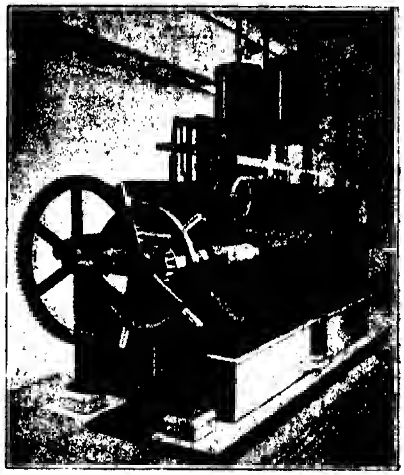

FIG. 10
Oerlikon Electrolyser

Most cells for the production of hydrogen and oxygen by electrolysis of water containing caustic soda are of the diaphragm type. The earlier non-diaphragm type, such as the Garuti and Schoop cells, contained electrodes each of which was almost completely encased by a bell of metal or earthenware. The only cells now used in which this method is employed are those of the Oxygen, Hydrogen and Plant Company, whose cells are based on the original design of Jaubert (see Fig. 7), and the Schuckert cell.

It is possible to construct the face of the electrodes either with projecting vanes or similar structure, so that the gas given off from each face rises immediately, in close proximity to the electrode face, to its appropriate collecting reservoir. This construction is utilised in the electrode of the Churchill cell and that of the Casale cell for generating electrolytic gas.

The Churchill cell is of the filter-press type, each bi-polar electrode being constructed of iron on the surface of which glass vanes are fixed in order to prevent the mixing of the gases evolved from

adjacent faces. Each electrode is insulated from its neighbour by a rubber joint, which also renders the electrolyser water-tight when the plates are screwed firmly into position. In the Casale cell each electrode consists of a pile of sheet-iron strips, 5 (Fig. 8), bent to form a rectangular frame with sloping sides. A terminal member, 6, of similar shape, is arranged above the column, 5, so that its upper surface projects above the level of the liquid. The cover of the vessel is provided with partitions, 12, extending to form a closed cell above each electrode, and each cell is provided with a delivery tube, 14. The electrodes are alternately anodes and cathodes, and between them a descending movement of the electrolyte is set up by the ascending movement, due to gas evolution, taking place inside the electrodes, which are fed with electrolyte through gap, 17, at the bottom of the electrodes. This cell is in use in Italy.

In a modified form of the cell the cathode consists of a cylindrical sheet, 22, provided with sloping gaps and an unperforated cylinder, 21, connected to it at the bottom by an annular plate, 23. The anode is mounted within the cathode and consists of an outer cylinder with sloping gaps and an inner unperforated sheet, the space between the electrodes being closed at the top by a plane annular disc, 27, fixed to the partition, 24. E.P. 200,376/22.

The Schuckert cell (Fig. 9), widely used in Germany before the war, and even at the present time, somewhat resembles the "Oxylithe" cell of the Jaubert Company, referred to above. Each iron electrode is encased by an iron bell, and the container holding electrolyte (caustic potash solution) is also of iron, the whole being placed in a wooden box filled with sand to prevent loss of heat by radiation. These cells require a lower voltage than diaphragm cells, but the purity of the gases is not high, occasionally falling to 90 per cent.

Diaphragm cells which are at present important will now be briefly described. All are made in 500 up to 2000 ampere units, and give approximately 7·0 cb. ft. of hydrogen per kw.-hr., except in the Schmidt Oerlikon filter-press type, of which the output is sometimes not more than 6 cb. ft. per kw.-hr.

The construction of the Schmidt unit will be clear from the illustration (Fig. 10). The number of cells per unit ranges from 30, requiring 70 volts, to 130, requiring 300 volts; and, owing to the filter-press structure, the plant is fairly inexpensive. Each plate is separated from its neighbour by sheet asbestos, which prevents mixing of the hydrogen and oxygen given off from adjacent faces of the bi-polar electrodes.

The Davis-Bournonville cell (New Jersey) is an improved form of the tank cell which was introduced in the United States about 1911. The outer tank of iron forms the cathode, whilst the anodes, L, suspended from the lid are each encased in asbestos sheet, K. Two or more anodes may be present, and between them auxiliary sheet iron cathodes, M, in contact with the tank itself may be fixed. The lid carrying the anodes and asbestos diaphragm is, of course, insulated from the tank. A view of the tank and interior is given in Fig. 11.

The Levin cell of the Electrolabs Company, Pittsburg, and the I.O.C. cell of the International Electrolytic Plant Company, England, are somewhat similar, and are illustrated in Figs. 12 and 13. Both are flat diaphragm cells, a 600-ampere unit of the Levin type having outside dimensions 43 in. by 37 in. by 8½ in., with an output of 9·6 cb. ft. of hydrogen per hour. The I.O.C. cell is flatter, because the anode and cathode plates form the casing of the cell, being separated from each other by a suitably clamped

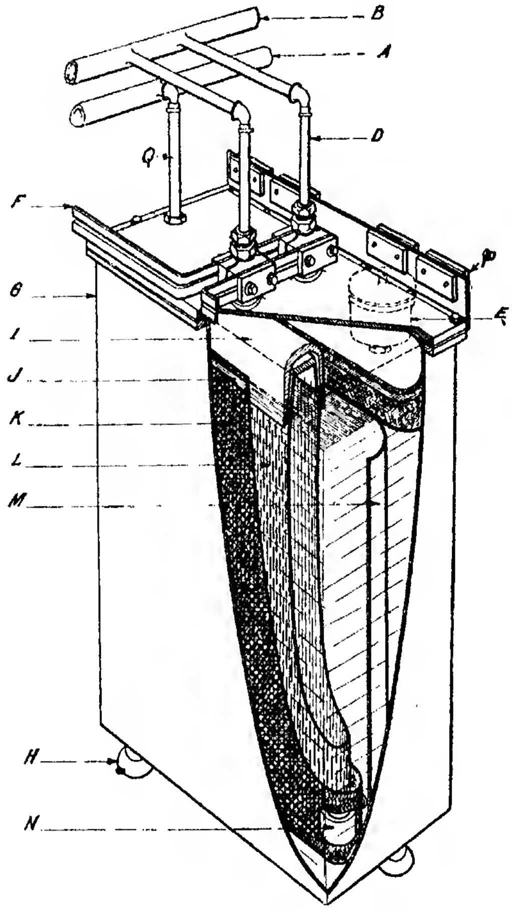

Fig. 11
Davis-Bournonville Cell

diaphragm; whereas the Levin cell contains two anode plates and two cathode plates separated by a diaphragm, and external to these, on each side, is the outer casing, which does not act as an electrode but only as a container.

No special device is needed for purifying the gases evolved, as their purity is usually about 99·5 to 99·8 per cent. A detailed explanation of the structure of the cells is not necessary, as the diagrams show all essential parts and indicate their relation to each other.

The last cell to be described is the Knowles Cell of the International Electrolytic Plant Company. This is an efficient multipolar iron cell which is somewhat less expensive than some of those already described, and which has recently been developed into a column cell with considerable economy in floor space when compared with other cells for generating hydrogen and oxygen.

Each cell consists of a tank in which anodes and cathodes, AA, are suspended alternately, each covered by a collecting bell, BB, and encased by asbestos diaphragms, LL (Fig. 14). Electrode bolts, CC, from which the anodes and cathodes are suspended, are insulated from the sealing tubes, DD, by ebonite tubes, EE, and top insulators, FF. Copper connexions, GG, connect the two bolts on the same electrode whilst HH are copper strips connected to the electrodes in parallel. Collecting pipes, JJ, serve to lead away the gases to the main off-take pipes, KK, whilst the skirting, MM, surrounds the entire block of bells and forms a stand on which it rests when lifted from the cell for examination.

The column cells shown in Fig. 15 are similar in design, but the superimposed arrangement is new, and allows a plant of high capacity to occupy exceptionally small space. Current passes from each cell to the one above, external current connexion being made only to the bottom and top cells, since the polarity is reversed as the current passes from cell to cell. Upstanding electrodes, A, on the base of one cell alternate with electrodes, B, hanging from the base of the cell above and form the anodes and cathodes of one cell unit. Asbestos diaphragms, C, hang from the bell plate, D, and prevent the gases which collect in spaces, E and F, from mixing.

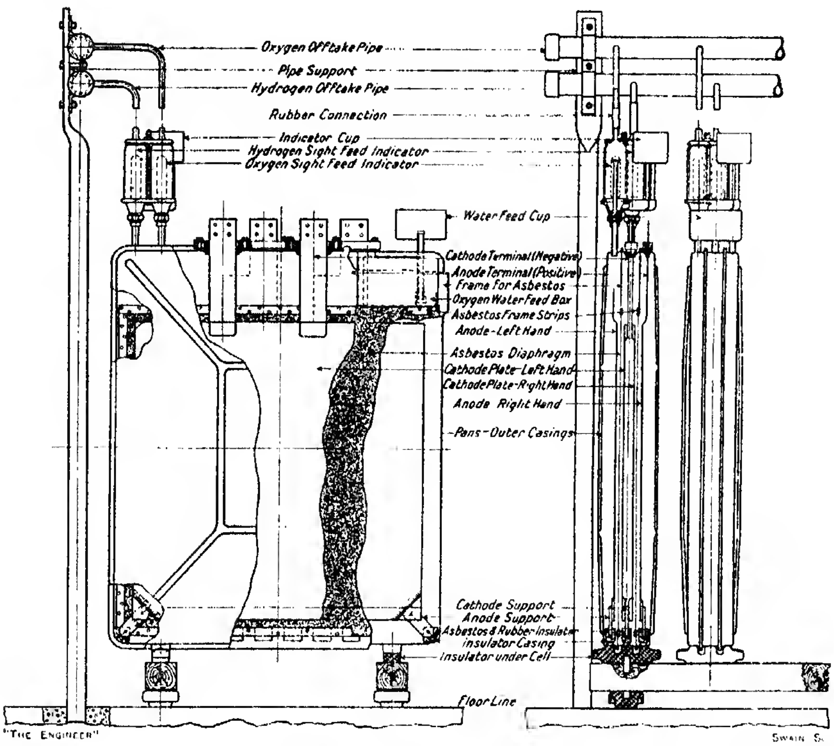

Fig. 12

Levin Electrolytic Cell

All the tanks are identical and interchangeable, so that any one may be used for the bottom cell, without risk of failure from the weight above.

The tanks of adjacent cells are insulated from each other by jointing rings, L, which also form a gas-tight ring and insulate the bell plate from both the tank above and below it. Copper bars, NN, carry the current between the top cells and bottom cells of adjacent columns which may be arranged ten or twenty cells high.

The voltage required by most of the cells described is 2·1 to 2·5 volts, and the energy output 7—7·5 cb. ft. of hydrogen per kw.-hr. with half this amount of oxygen. A 600 ampere unit will give in most cases 9·6 cb. ft. of hydrogen per hour.

CELLS FOR PRODUCTION OF CAUSTIC SODA AND CHLORINE

These are of great importance to-day and belong to one of three groups—*i.e.*, mercury cells, bell cells, or diaphragm cells, the last being the most important and most generally used.

The Castner rocking cell (1895) was followed later by the stationary Solvay-Kellner cell of larger dimensions (Fig. 16), and this is still used in the alkali industry. The cell itself is a large rectangular tank of cement along the floor of which a layer of mercury is caused to flow from one end to the other. This mercury cathode is in electrical contact with leads passing through the bottom of the tank and immediately over it are suspended the graphite anodes. As the thin mercury layer flows slowly through in contact with the brine electrolyte passing in the same direction, a sodium amalgam is formed which is decomposed by water in a separate tank with formation of caustic soda liquor. The liberated mercury is passed back to the cell whilst the chlorine discharged on the anodes is drawn off by an outlet pipe

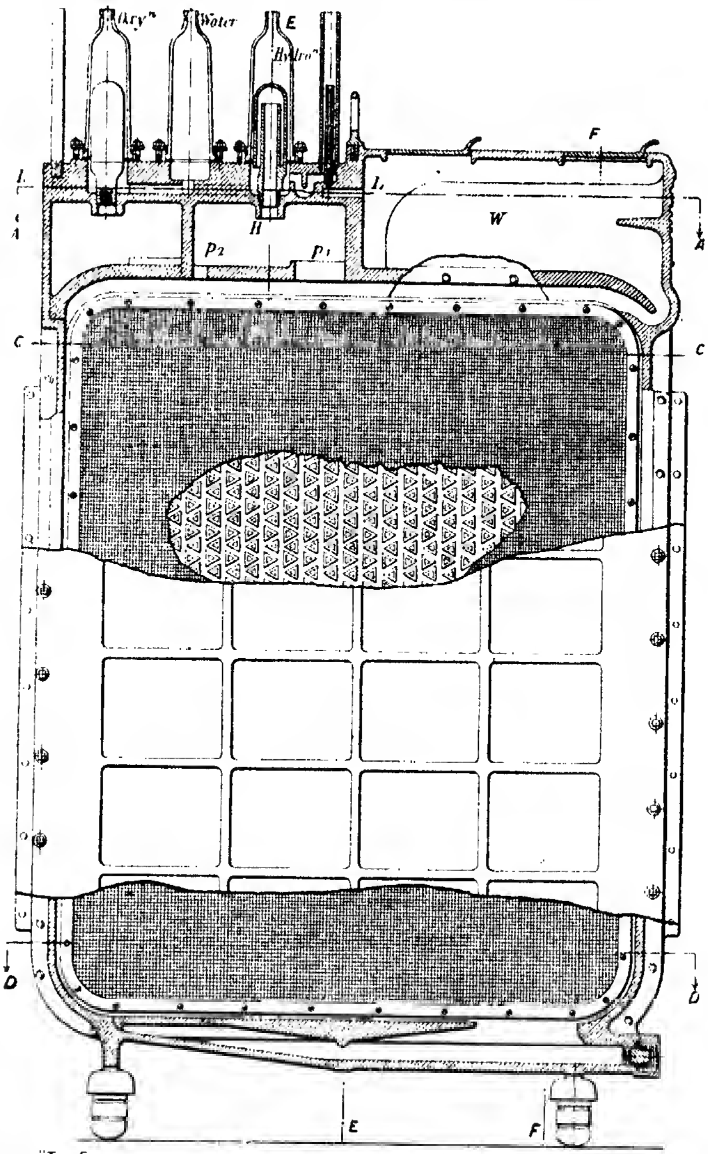

FIG. 13

I.O.C. Cell

on the top of the electrolytic tank. Cells taking as much as 4000 ampères have been constructed. The Wilderman cell is the only other mercury unit which has met with any success, a large installation being worked for some years in Germany before the War. A vertical section through one of the cylindrical cells (Fig. 17) shows that the mercury is contained in circular V-shaped channels which divide the central anode compartment from the outer cathode chamber. By means of stirrers, BB, fitted with ebonite blades, the mercury is kept in motion so that a greater concentration of sodium for a given weight of mercury can be obtained than in most cells of this type, because there is less tendency for solid amalgam to form when current densities greater than 6—8 ampères per dm^2 are employed. Recently, improvements in the design of the cell have been patented, in order to accelerate rate of working, and possibly it will continue in use where already installed.

In connexion with the Castner-cell production of sodium amalgam, its use as a reducing agent in plant for dealing with nitro-compound has been patented (E.P. 200,167/23), whilst another process (E.P. 198,855/22) deals with a method for producing sodium amalgam by electrolysis of brine and utilising it in another compartment for effecting chemical reaction—*i.e.*, the reduction of oxalic acid to glyoxylic acid.

Bell Cells or gravity cells usually consist of cement troughs or tanks in which a number of earthenware bells are suspended which encase the graphite anodes. These alternate with iron cathodes and the separation of caustic soda from the chlorine is effected by the flow of liquid from the bell or anode compartment to the cathode, from which caustic soda liquor overflows.

Such cells have been in use at Aussig and other Continental works for many years, as also have installations of a similar cell, the Billiter-Leykam bell cell (Fig. 18), and a recent type due to H. C. Jenkins, the illustration of which (Fig. 19) will show the principles involved. The Billiter-Leykam cell, which dates back to 1910 (E.P. 11,693/10), and is still in use on the Continent (Austria), is an improved form of the original bell cell in that the overflow takes place from the bottom of the cell and the iron cathodes, C, are encased in asbestos to facilitate the removal of hydrogen. The chlorine is drawn off from the top of the bell by the pipe, B, and fresh brine supplied through D.

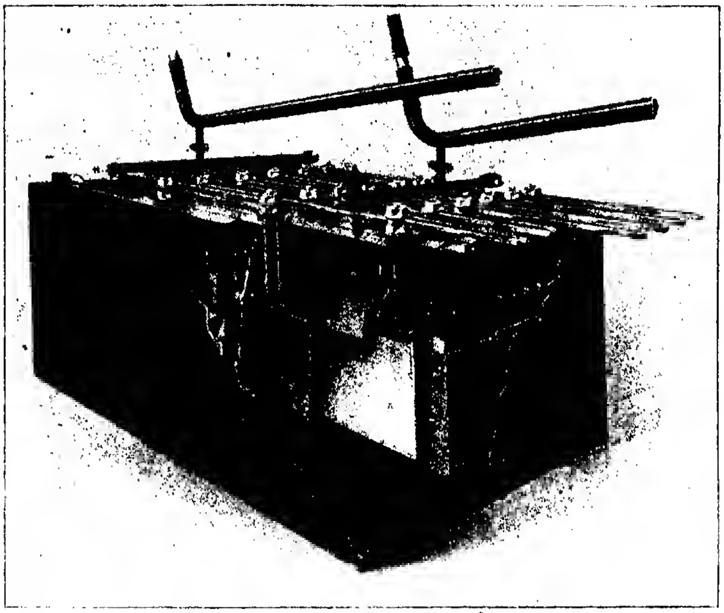

FIG. 14

Knowles Cell

Jenkins bell cell (Fig. 19) consists of a shallow concrete tank about 25 ft. long, 2·5 ft. high, and about 2 ft. deep, the floor of which is corrugated and the base of which is provided with four longitudinal pipes 10, 11, 12, 13, which open to a particular part of anode or cathode space. The pipe 10 is for emptying the tank when it is to be shut down, and is connected with depressions in the floor; pipe 11 supplies fresh electrolyte to the anode spaces; pipe 12 serves for removal of chlorine whilst caustic alkali is drawn off by pipe 13.

The anodes 2 are rectangular blocks of graphite arranged transversely across the cell, and are attached to the bells which enclose them by two graphite rods, 4 and 5. These anodes almost fill the bells, leaving only a small space for the anolyte. An iron cathode 6 is situated between each pair

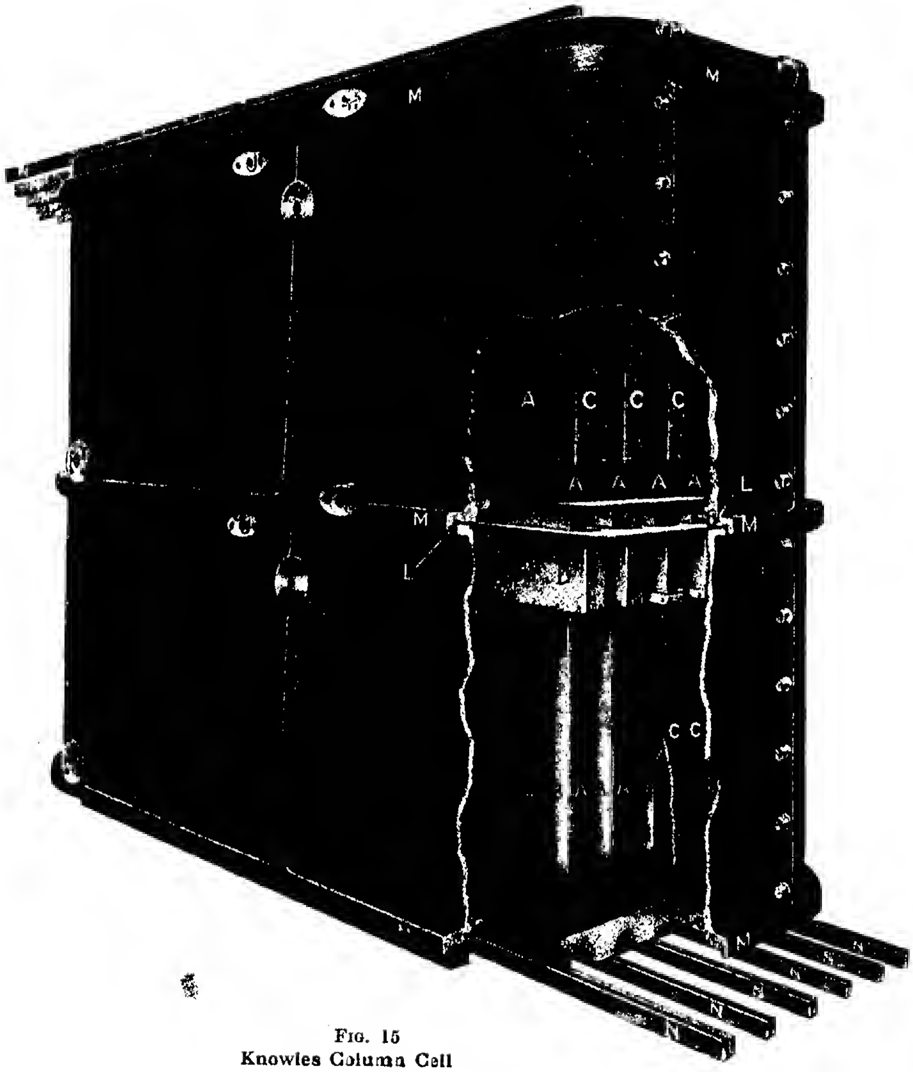

Fig. 15
Knowles Column Cell

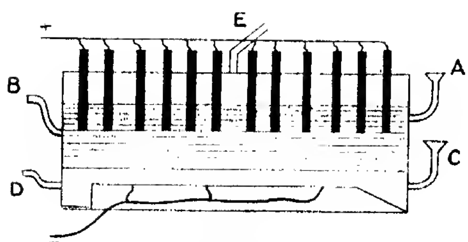

Fig. 16
Solvay-Kellner Cell

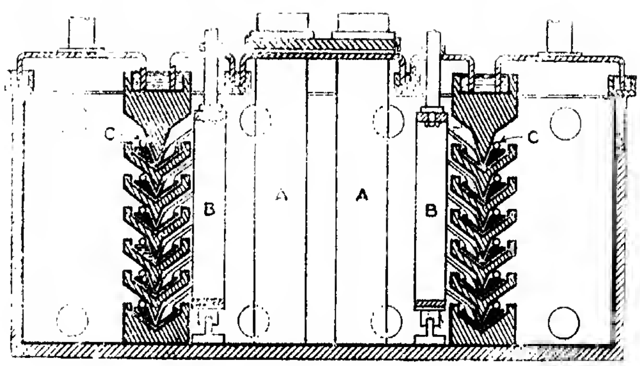

Fig. 17
Wilderman Cell

of bells, and is fitted with a collector 7 for hydrogen. All cathodes are connected to a bus bar 8, and are situated above the depressions in the cell floor, whilst all anodes are connected to the bus bar 9.

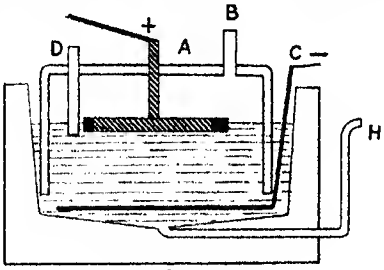

FIG. 18
Billiter-Leykam Cell

Fresh electrolyte is supplied at intervals through jets 20, which discharge into a small well 10, connected with the pipe 11, this liquid subsequently overflowing into a second well 17, containing an annular float 18. The liquid cannot escape out of 17 except by the path through which it entered, but it does so escape when the supply of liquid from the jet is cut off. The float 18 then falls back to its original position. Working at 4 to 4·5 volts per cell, a caustic soda liquor of 10-12 per cent. concentration is obtained.

(To be continued)

Virtue and Co., Ltd., and Figs. 16, 17, 18, 21, and 27 from the author's monograph on "The Applications of Electrolysis in Chemical Industry," published by Messrs. Longmans, Green and Co. Acknowledgment is due to both these firms for permission to reproduce these figures and for their kindness in lending the blocks. Thanks must also be tendered to the other firms who have lent illustrations of their products.]

SOUTH AFRICAN IRON INDUSTRY

It is reported that a representative of the South African Iron and Steel Corporation is at present in London "probably conducting negotiations for the establishment of an iron industry in South Africa." It is also stated that the report of the four steel experts—Drs. Kipper, Lilge, Philippi and Reusch—who visited South Africa last year at the instance of the South African Iron and Steel Corporation to investigate the possibility of utilising South African iron ore at Pretoria and in other parts of the country, is now in the hands of the Government and is believed to be most favourable. The Government organ, *Ons Vaderland*, on the other hand, states that no report has been received, but adds that the Government would support any reasonable proposal made to it.

FORTHCOMING EVENTS

Dec. 13. SOCIETY OF CHEMICAL INDUSTRY and INSTITUTE OF CHEMISTRY, *Birmingham and Midland Sections*, The Annual Dinner, Queen's Hotel, Birmingham at 6.45 for 7 p.m.

Dec. 15. ROYAL COLLEGE OF SCIENCE MATHEMATICAL AND PHYSICAL SOCIETY and the IMPERIAL COLLEGE CHEMICAL SOCIETY, at Royal College of Science, S. Kensington, S.W. 7, at 5 p.m. "Intense Magnetic Fields," by Dr. T. F. Wall.

Dec. 15 to 20. UNIVERSITY OF LEEDS. Jubilee of the Yorkshire College, and Coming of Age of the University.

Dec. 16. WEST OF SCOTLAND IRON AND STEEL INSTITUTE. "The Application of Producer and Coke Oven Gas to the Metallurgical Industry," by Prof. R. V. Wheeler.

Dec. 17. INSTITUTE OF CHEMISTRY, *London Section*, 30, Russell Square, London, W.C. 1.

Dec. 17. SOCIETY OF CHEMICAL INDUSTRY, *Newcastle-on-Tyne Section*, Armstrong College, Newcastle-on-Tyne, at 7.30 p.m. (1) "A Method of Measuring Specific Inductive Capacity," by L. A. Sayce and H. V. A. Briscoe. (2) "The Electrical Explosion of Tungsten Wires," by H. V. A. Briscoe, P. L. Robinson and G. E. Stephenson. (3) "A Redetermination of the Atomic Weight of Bromine; and an attempt to confirm that Isotypes are inseparable by Fractional Crystallisation," by P. L. Robinson and H. V. A. Briscoe. (4) "The Use of Fused Borax in Determination of the Atomic Weight of Boron," by H. V. A. Briscoe, P. L. Robinson, and G. E. Stephenson. An exhibition of Pyrex laboratory ware and blown Pyrex glass will be made.
Visit to the Wear Flint Glass Works, Millfield, Sunderland, will be made, leaving Newcastle at 1.17 p.m.

Dec. 18. INSTITUTE OF CHEMISTRY, *Belfast and District Section*, Queen's University, Belfast, at 7.30 p.m. "The Rutherford-Bohr Atom from a Chemical and Physical Standpoint," by Dr. R. C. Johnson.

Ingold.

Dec. 19. SOCIETY OF CHEMICAL INDUSTRY, *South Wales Section*. Joint Meeting with the Institute of Chemistry, the Chamber of Commerce, Exchange Buildings, Swansea, at 6.30 p.m. "Fire Damp Explosions," by Prof. R. V. Wheeler, D.Sc.

SOCIETY OF CHEMICAL INDUSTRY

SUSPENSION OF ENTRANCE FEE

As an inducement to Chemists to become members, the Council has resolved that no entrance fee shall be paid by members joining the Socioty in 1925.

A form of application for membership was inserted at the end of this Section in the issue of the Journal for October 17, and it is hoped that it may be used to introduce a new member for next year.

BACK NUMBERS OF JOURNAL

The General Secretary will be glad to hear from Members or Subscribers who have copies of the *Journal* for January 4, June 13 and 27, July 4 and 25, September 19, or October 3 and 17, 1924, that they are willing to dispose of to the Society.

DEATHS

Hake, C. Naper (Original Member) of the Oriental Club, Hanover Square, London, W.1. Chemical Adviser On Oct. 16, 1924.

Collett, J. M. (elected 1887) of Wynstone Place, Brookthorpe, Gloucester, Chemical Manufacturer. On Nov. 25, 1924.

BRISTOL SECTION

The third meeting was held jointly with the Institute of Chemistry, at the University, Mr. M. W Jones occupying the chair. A paper was to have been read by Mr. W. E. Fearnsides, of Messrs. L. B. Holliday and Co., Ltd., of Huddersfield, on "Some International Aspects of the Dyestuffs Industry," but owing to his absence in Central Europe Mr. H. N. Cliffe deputised.

After outlining the history of dyestuffs the lecturer discussed modern dyestuffs, and pointed out that the arguments for supporting the dyestuffs industry in Great Britain are based on a national outlook only, whilst the international view was largely neglected. There was a great change during the past fifty years in the colour trade, and nothing short of a "dyestuffs famine" would bring home to the nation what it would mean to be again in the position existing before any synthetic colours were available in the dyehouse, and only a strictly limited number of vegetable dyes which were difficult to apply and very unequal in fastness. From the seventies onwards ranges of dyes were produced at periods of about ten years, each range possessing greater fastness than its predecessor, and each marked by a flood of patents. This periodicity had not been maintained since 1910, and was not likely to recur because we had now almost arrived at the point when a nearly complete range of fast colours, no longer protected by patents, would be produced on every fibre and material.

The situation now developing was fundamentally different from the forty years of rapid development which preceded 1914. It would inevitably tend to the formation of rings and the elimination of less efficient units. The present development of the rings was indicated, and factors making for efficiency, permanence and competitive power were discussed. Among these factors were availability of raw materials; financial or economic soundness; trained and experienced personnel and maximum output based on widespread markets and complete range. These points received full treatment and particularly was the necessity urged for the extension of our overseas trade in dyes. Vast markets in Central Europe, South America, China, India and Scandinavia, together with the growing demands of our Colonies, were open to our products and there was the possibility that our production could be multiplied several times if we could satisfy foreign demands as to quality, price and service. This took time and required much hard work, but it could be and was being done.

The paper resulted in an excellent discussion in which Dr. Rixon and Messrs. Marsden, Southerden, Storey, Waterfall and others took part. Mr. A. Marsden read a letter from Mr. Fearnsides, apologising for his absence, and Mr. M. W. Jones gave an interesting account of his personal associations with some of the pioneers of the dyestuffs industry. The proceedings concluded with a hearty vote of thanks to Mr. Cliffe.

LIVERPOOL SECTION

A meeting was held in the Muspratt Lecture Theatre, The University, on December 5, Mr. Alfred Smetham in the chair, in the unavoidable absence of the chairman of the Section. A paper was read by Dr. Percy Lewis-Dale on "Liquid Hydrocarbons obtained in the Compression of Oil Gas."

The liquid was a by-product obtained when oil gas was submitted to a pressure of 150 lb. per sq. in. In 1825 Faraday discovered benzene in a similar liquid, and in 1884–6 H. E. Armstrong and A. K. Miller found many olefines, naphthenes and benzenoid hydrocarbons, but only traces of paraffins, whilst true acetylenes were absent or practically so. The liquid now examined contained an appreciable though small amount of mono-alkyl acetylenes, and acetylenes were also present in the gas from which the liquid was derived. Agreement was reached with the results obtained by Armstrong and Miller. There was little doubt that the liquids examined by these authors and by Faraday were of the same general character as that under discussion, although produced by different methods. The best use that had been made of the liquid in recent years was in the manufacture of a motor spirit of high volatility and great propellent power. Unfortunately, the tendency of the spirit to resinify militated against its use, and further, in view of the low cost of petrol, it was doubtful if the manufacture was an economical proposition at present.

A good separation of the constituents of various classes had been effected by careful fractionation. Unsaturated open-chain compounds of the general formula C_nH_{2n} were found in larger quantity than those of formula C_nH_{2n-2}, especially C_5H_{10} in much larger quantity than C_5H_8. Many ring compounds were found. The olefines were highly reactive, and some use might be made of them in industry. A suitable fraction might be used as a turpentine substitute, and possibly a satisfactory and economical motor spirit might be produced from a portion of the remainder, but perhaps the most profitable use of the liquid would be its return to the retorts

with the original uncracked oil. The higher boiling fractions were exceedingly complex and very interesting, and might form the subject of further investigation.

The quantity of liquid produced was limited by the amount of oil gas manufactured, and the use of oil gas was only possible where circumstances demanded the employment of the richest gas obtainable. Its use was practically confined to gas for cooking in railway restaurant cars and for light-buoys. In the past the chief use of the gas was for train lighting, but for this purpose electric light was becoming general.

After some discussion, a hearty vote of thanks was passed to Dr. Lewis-Dale, on the motion of Mr. W. Mansbridge, seconded by Prof. W. H. Roberts.

MANCHESTER SECTION

Dr. H. Levinstein presided over an attendance of fifty-five at the meeting held on December 5 when Mr. A. V. Slater read a paper on "Peptisation." The paper was an argument for the "complex" theory of colloidal solution, peptisation being a special case of true solution. Graham's definition of peptisation as the transformation of a gel to a sol by addition of a dispersing agent, was accepted, and the conditions for peptisation were discussed. A substance could be peptised if present in gel form with particles not above colloid dimensions. It could be peptised by a substance that was easily adsorbed by reason of primary or secondary valence forces. The colloidal particles were drawn into solution by the solution pressure exerted by the peptiser. Ions of low electro-affinity of the same sign of charge as the colloid, combined with ions of small coagulating power which increased the potential difference within a wide limit of concentration, would be good peptisers, and the peptiser must possess a high solution pressure of its own. In general, substances capable of forming soluble compounds with the colloid in high concentration would peptise easily in low concentration; raising the temperature and increasing the pressure would enable some substances to peptise a colloid which at lower temperatures and pressures were unable to overcome the cohesion of the colloid. If a peptiser did not exert sufficient solution-pressure or the eventual formation of a soluble complex salt of high concentration, the concentration must be kept low to prevent flocculation.

The rest of the paper consisted of a classified list of peptisations, concluding with a discussion of deflocculation.

MONTREAL SECTION

At the meeting held on November 17, Mr. L. H. Cole, of the Mines Branch, Dominion Government, Ottawa, stated that Canada had salt deposits of approximately 100,000,000 tons in the western provinces, and chiefly in Saskatchewan, but there was little hope of their industrial development in face of the tremendous competition of Great Britain and the United States, unless the freight rates for these salts from the west were sufficiently low to allow it. About 90 per cent. of the deposits of Saskatchewan had been found to be sodium salts with a 10 per cent. admixture of clays and other salts. In 1921 a thorough examination of the contents of the western lakes revealed some 100,000,000 t. of hydrous sodium and magnesium salts, in deposits varying from two or three inches to 140 ft., samples, on analysis, proving to contain about 90 per cent. of sodium salts. Near the lakes were salt and fresh water springs, and in the lakes themselves were found both intermittent and permanent beds, the former being the ones that were now worked. The permanent beds lay underneath, whereas the intermittent beds were formed by the seasonal crystallising of salt deposits on the surface of the lakes. More or less successful attempts had been made to deal with the salts industrially, and there are several companies harvesting the intermittent deposits. Investigation had also been made of deposits in British Columbia, where sodium carbonate and bicarbonate deposits had been found that were used in the manufacture of soap. In the discussion that followed, Mr. Cole stated that although they had found no potash of any importance in the West there was a possibility that there were deposits hidden there by the mud.

SOCIETY OF PUBLIC ANALYSTS

Four papers were read at the meeting held on December 3, Mr. G. Rudd Thompson in the chair :—

(1) "The Analytical Value of the Melting Point of the Insoluble Volatile Acids from Fats," by G. Van B. Gilmour, B.Sc. The method put forward by Blichfeldt for distinguishing between and estimating coconut and palm-kernel fats in mixtures is investigated. It is found that the method has considerable limitations, especially when there is a preponderance of other fats present. The melting points of the insoluble volatile acids from a number of edible oils and fats are given and it is shown that as little as 1 per cent. contamination with coconut or palm-kernel fat can be detected by the lowering of the melting point. The volatility of oleic acid in ordinary distillations is demonstrated.

(2) "The Use of Mitchell's Ferrous Tartrate Reagent in Qualitative Analysis," by A. H. Ware. The author describes and discusses results obtained by the use of Mitchell's reagent with plant extractives in the presence and absence of alkalis, including a new modification of the test in which acetic acid is used. He finds the test in its different variations to be of very great value in plant analysis and pharmacognosy. A list of a considerable number of phenolic bodies of different classes is given, including catechol-bodies, giving in plant extractives a good violet colour-reaction to the test, in the presence of definite amounts of alkali; also of catechol-bodies, which, although they resemble those of the first list in giving good green colour reactions with ferric alum, yield no violet colour to the test under discussion. The test affords a useful means of distinguishing between ipecacuanha extractives and a number of other extractives yielding a green colour to ferric alum, but which, like ipecacuanha, do not contain tannin. The modification of the test given

by boiling with dilute acetic acid after adding the iron reagent affords a very valuable means of distinguishing between two classes of gallic acid tannins. Those of one class give a good blue or violet colour reaction under the conditions named, whilst those of the other class do not show this result. The author gives a list of drugs and tanning materials falling into the two classes referred to, and proposes that the term "gallotannins" should be confined to tannins which give the blue or violet coloration to the acetic acid modification of Mitchell's test.

(3) "The Influence of Hydrogen-Ion Concentration on the Colorimetric Estimation of Pyrogallol and Catechol Derivatives," by S. Glasstone, M.Sc., Ph.D. The maximum intensity of coloration with Mitchell's ferrous tartrate reagent is obtained within the limits of p_H 6·5 and 10·3 for pyrogallol, 5·9 and 10·3 for gallic acid, and 4·1 and 11·1 for gallotannin. Hence the conditions described by Mitchell are suitable for obtaining equal intensities of the violet colour. In the case of catechol derivatives, however, the limits are much narrower and suitable adjustments of the p_H value are necessary to obtain quantitative results. The author recommends the addition of ammonium acetate, to act as a buffer and to give a p_H value of about 7·6.

(4) "The Futility of Sealing: A Suggestion for its Safeguarding," by B. S. Evans, M.B.E., M.C., B.Sc. The suggestion is made that plain wax seals should be used on which the person sealing should write his initials in special ink. A number of these inks should be kept, consisting of ordinary ink holding in solution substances easily identifiable in minute traces. The person breaking the seal would, after identifying the signature, dissolve it off the wax and test the solution for the key substance of which he would be privately notified.

SOCIETY OF GLASS TECHNOLOGY

A meeting was held in the Coal Gas and Fuel Industries Department, The University, Leeds, on November 19, the President, Col. S. C. Halse, in the chair. Four papers were presented and discussed.

(1) "Note on the Glasshouses of the Leeds district in the 17th, 18th, and early 19th Centuries," by Francis Buckley. John Houghton, writing in 1691, stated that there were then three glasshouses in Yorkshire, one near Ferrybridge, and two near Silkstone. They could now identify these as the glasshouses at Houghton, Bolsterstone and Silkstone. Henry Fenny was in possession of the Houghton glass factory in 1740, but by the end of the century the business had ceased. The glasshouse at Rothwell Haigh was erected before 1726. A good description of it appeared in the *Daily Post* of March 10, 1726. From the Rothwell Registers it was fairly evident that the firm which took the glasshouse in 1726 included Stourbridge glassmakers. The last actual mention of the glasshouse was in 1773.

The only glasshouse actually in or near the town of Leeds in the eighteenth century was known as the Engine Glasshouse, and this was probably the factory that supplied all the ordinary needs of the town for the greater part of the eighteenth century. It could be traced between 1738 and 1770. The Engine Glasshouse might have been the present as well as the predecessor of the famous Hunslet Glass Works, though the connexion had still to be proved. Between 1814 and 1861 at any rate, the Bower family had several factories there. The people of Leeds must have owed as much to this family in the nineteenth century, as they did to the Fennys in the previous century. In 1883 they had four glasshouses at work, and no competition in the town itself. Just before 1850, however, there was a sudden increase in the glass concerns in Leeds and the surrounding district, especially in the neighbourhood of Castleford.

An early nineteenth century glasshouse at Thornhill Lees could be traced back to 1830. Here Noah Turner made flint glass until the glasshouse was taken over by the Kilners before 1847, and converted into a bottle works. There was a glasshouse also at Worsborough Dale in 1833, worked by William Usherwood, but in the following year Messrs. Wood and Perkes were found in possession, making cut-glass.

(2) "A Striking Instance of Fireclay Corrosion through the Action of Saltcake," by Prof. W. E. S Turner, D.Sc. During the emptying of a glass tank with the gas-flame still running, the fireclay blocks surrounding the dog-hole in a bottle-glass furnace began to swell and to flow, soon after they became exposed to the action of the flame, as the tank was drained. There was a suspicion that when the tank was started a charge of saltcake had been put into the dog-hole, under the belief that the blocking of the hole would be prevented. After examination it was found that the exposed portion of the blocks had absorbed saltcake at an early stage in the operation of the furnace, and being covered with glass and the dissociation temperature very high, the saltcake had remained unattacked, until contact with the flame during the emptying of the tank brought about decomposition.

(3) "A Note on some Properties of a Sandstone Block after use in a Glass Furnace," by H. S. Houldsworth, M.Sc. In the experiments described refractory material (Penshaw stone) and glass were ground separately until they passed a 100 mesh I.M.M. sieve, and were then thoroughly mixed in the desired proportions. A little gelatin solution was added, and cones were shaped from the mixture. These were then heated alongside standard Seger cones in a gas-fired laboratory furnace. The results obtained indicated that powdered Penshaw stone interac as readily with a soda-lime glass as did powd or good fireclay bricks. Penshaw stone devel a close compact structure when used in a furnace. This tended to hinder the penetratio glass into the stone, thus adding to the life of refractory, and pointing to its successful use furnace-construction.

(4) "The Production of Colourless Glass in Tank Furnaces, with special reference to the use of Selenium. Part IV. The Influence of Arsenious Oxide," by A. Cousen, M.Sc., and Prof. W. E. S. Turner, D.Sc. Previous work by the authors had shown the great influence of arsenious oxide in

preventing the development of colour in a selenium decolorised glass. It was evident that some of the effect was due to the action of the oxide upon the iron present. In confirmation of this fact meltings of a glass batch with addition of various quantities of arsenious oxide were made, and the colour of the glass was found to be less the more of the oxide there was in the batch. This then was the first important effect of arsenious oxide in decolorising; the second consisted in the suppression of the brown selenium colour. From this point of view selenium and cobalt oxide were only secondary materials in the decolorising process. The pink colour due to selenium was developed at the commencement of melting. For its successful production it required a hot furnace for the first stages of melting, and a low iron oxide content of the glass. An attempt to réplace arsenic by its equivalent of phosphorus in the form of calcium phosphate showed the latter substance to have little or no effect upon the brown selenium colour. Antimonious oxide used instead of arsenious oxide with selenium gave a deep bluish green colour. The cobalt oxide required in decolorising was about 1/12 oz. per 1000 lb. of sand, and this quantity could not be increased by 50 per cent. without producing a distinct blue colour in the glass.

UNIVERSITY OF BIRMINGHAM CHEMICAL SOCIETY

At a recent meeting Mr. S. H. Edgar, B.Sc., read a paper on "The Chemistry of Blood." An outline of the chemical theories of coagulation was followed by a brief study of the blood-pigments and the compounds of hæmoglobin with gases. The exchange of oxygen between the blood and the tissues was then dealt with from the chemical standpoint, and the latter half of the paper was devoted to a survey of the study of immunity. The nature of toxins and anti-toxins was briefly discussed, and the theory of antibody formation in the blood was explained by means of Ehrlich's sidechain hypothesis. A few practical applications of immuno-chemistry were mentioned, in particular the precipitin test used in criminology.

At the last meeting a paper on "The Bohr Theory of Atomic Structure" was read by Mr. R. E. Kellett. The lecturer showed how the theory enunciated by Bohr in 1913, from being merely a physical interpretation of the Balmer-Ritz spectral formula in terms of Rutherford's atom and the quantum theory, had now developed through the recent work of Bohr and others into something of the greatest importance to the chemist. Not only did the extended Bohr theory interpret the phenomena of radiation, but it gave an explanation of photochemistry, catalysis, activation, theories of the union of atoms into molecules, and not only outlined the architecture of even the most complex atomic structures, but also explained the known regularities and the apparent irregularities of the Periodic System (*e.g.*, the apparently anomalous behaviour of manganese and iron, and the unexpected appearance of the rare earths group of elements). More important still it had given rise to valuable predictions and discoveries, such as the new element hafnium.

CHEMICAL SOCIETY

Before scientific communications were made at a meeting held on Thursday, December 4, the President, Prof. W. P. Wynne, referred to the address of congratulation which he would shortly present, on behalf of the Council and Fellows, to the University of Leeds on the occasion of the jubilee of Yorkshire College.

The first two papers were read by Mr. H. Burgess:—

New halogen derivatives of camphor. Part VI. β-Bromocamphor-α-sulphonic acid. [With T. M. Lowry.]

(*a*) A SERIES of α-sulphonic derivatives of camphor is described.

(*b*) Since these were only obtained when a halogen atom occupies the β-position, the view that β-bromocamphor and Reychler's camphorsulphonic acid contain the substituent in the same position is considerably strengthened.

(*c*) β-Bromocamphorquinone has been prepared and investigated.

New halogen derivatives of camphor. Part. VII. The constitution of the Reychler series of camphor-sulphonic acids. Experiments on chlorosulphoxides. [With T. M. Lowry.]

(*a*) α-BROMOCAMPHOR-π-CHLOROSULPHOXIDE has been prepared from the π-sulphonyl chloride and oxidised to *trans*-camphortricarboxylic acid.

(*b*) Under the same conditions *o*-toluenesulphonyl chloride does not give a corresponding chloro-sulphoxide.

(*c*) These experiments indicate that the conversion of a sulphonyl chloride to a chlorosulphoxide takes place when the sulphonic-group is linked to methylene, and not as a result of eliminating water with a neighbouring methyl-group.

(*d*) The conclusion is, therefore, drawn that no migration occurs during the formation of ketopinic acid from Reychler's camphorsulphonyl chloride, and consequently that the sulphonic group must be in the 10-position as stated by Wedekind.

Prof. T. M. Lowry said that the work had been rendered both difficult and interesting by the fact that at nearly every point the actions went in a different way from that which was expected. Reychler's acid had had a very curious history, since the radical had been put in position 2 by Reychler, in position 6 by Armstrong and Lowry, and now in position 10 by Wedekind; incidentally, in the confirmation of Wedekind's orientation, Reychler's dream of α-sulphonation had at last been realised. It was, however, very difficult to understand why 10-bromocamphor should always behave as if it were the 6-compound. It looked as if there were some sort of a linking between the two positions which was not shown by the conventional formula, like that which must exist between the ketonic group and the π and β methyl groups to account for their altogether unexpected sulphonation, and the complete neglect of the reactive α-atoms. The π-sulphonation of camphor

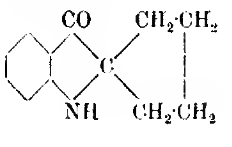
was also the only action in which the molecule underwent optical inversion; this had suggested to Armstrong and Lowry that the sulphonation might involve the rupture of the *gem*-dimethyl chain, with the formation of an intermediate compound derived from *p*-cymene, and the subsequent restoration of the chain on the other side of the 6-atom ring. The speaker had been working on camphor for over twenty-five years, and the camphor-chemist was still perplexed and fascinated by the many mysteries of that molecule.

In according very hearty thanks to the authors, and expressing the hope that the work would be continued, the President humorously feigned surprise that the results had not been interpreted in terms of the electron hypothesis, and that Prof. Lowry had discussed the work without even employing a + or − sign.

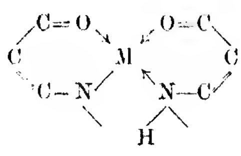
Dr. N. V. Sidgwick then gave an account of views which, he hastened with mock seriousness to explain, were fortunately conceived prior to the recent publication of a book prohibiting the application of electronic ideas to organic compounds. The substance of the paper was as follows:—

Some co-ordinated compounds of the alkali metals. [With S. G. P. Plant.]

THE action of alkali hydroxides on ψ-indoxyl-*spirocyclo*pentane (I) gives a substance MB, HB (M = Li, Na or K; HB = I) in which one metallic atom replaces one hydrogen atom in two molecules. The sodium and potassium derivatives can be recrystallised from toluene and lose one molecule of HB on heating, either alone or in toluene solution, forming no doubt the simple salt MB, which we should expect the indoxyl derivative to produce. There can be little doubt that the first product MB, HB contains a 4 co-valent metallic atom. The indoxyl ring admits of co-ordination between a metal replacing the imide hydrogen and the carbonyl oxygen, with the formation of the typical chelate ring of 6 atoms with two conjugate linkings (see formula II),



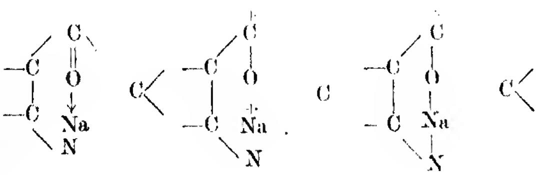
I



II

The strong tendency of the alkali metals to ionise will prevent the formation of this ring in the simple derivatives MB, which therefore are salts; but the greater stability secured by the completion of 4 non-polar linkings causes these compounds to add a second molecule of the indoxyl derivative (without replacement of hydrogen) giving the structure II. The remarkable solubility in toluene is thus explained, since the compound is not a salt. The sodium has its octet completed by means of three pairs of shared electrons borrowed from the two oxygens and the now quadrivalent nitrogen. The second ring, being attached only by co-ordinate linkings, is easily removed, and hence the compound dissociates on heating.

Prof. Lowry said that he was interested in the properties of Dr. Sidgwick's co-ordinated sodium-compound, because it appeared that the sodium-derivative of nitrocamphor did not possess these properties and must therefore be classed as a mere salt; also because of the dramatic verification of Dr. Sidgwick's own prediction that the co-ordination-number of sodium would be found to be 4 and not 2. He was, however, also interested in the structural formula assigned to the compound, since this showed all the bonds of a carbon atom pointing in the same downward direction. This he believed to be impossible in the case of a *quadrivalent* carbon-atom. On the other hand, in discussing the Walden inversion and the problem of "free rotation," he had urged that the three bonds of a *tercovalent* carbonium-ion, although they could easily become coplanar, need not necessarily assume this form, but might retain a "tetrahedral" configuration, since the NO_3 ion, although planar in sodium nitrate, is not so in lead nitrate. Dr. Sidgwick appeared to have carried out (perhaps unintentionally) a crucial experiment to determine whether the carbon atom in a cyclic co-ordination-compound is quadrivalent or tervalent, and to have proved that it must be tercovalent. The scheme I must therefore be incorrect and ought to be replaced, in this and in all analogous cases, by an alternative scheme, such as II or III, in which the carbonyl-group is ionised in such a way as to convert the quadrivalent carbon atom into a tervalent carbonium ion.



I II III

Prof. T. S. Moore briefly indicated how some of his own earlier results were now explained on the lines indicated by Dr. Sidgwick. Thus *o*-hydroxy-*m*-methylbenzophenone has only faint hydroxylic properties, and does not absorb gaseous ammonia. Two parts of the ketone with one of sodium in dry ether yield hydrogen in the cold until all the sodium is dissolved, whereas if equal parts are used hydrogen evolution stops while much sodium remains; on warming, the sodium ultimately disappears with slow evolution of hydrogen, but a solid sodium salt is precipitated.

Dr. Sidgwick confessed that he had not yet seriously contemplated a stereo-formula of the type suggested by Prof. Lowry. In connexion with Prof. Moore's remarks, he referred to the fact that *o*-nitrophenol, which is a co-ordinated compound, will not combine with aniline, whereas this is not the case with the other isomerides.

CORRESPONDENCE

THE TEACHING OF CHEMISTRY

SIR,—May I appeal, through your correspondence columns, for a more enlightened attitude on the part of those who control our qualifying examinations on chemistry ? It seems to me that this question is one of paramount importance, since it is to those who are now being ground in our educational mills that we must look for the future control of industry.

I hope I shall not be considered heretical when I state as my considered opinion that the present-day teacher of chemistry has to choose whether he will get his students through their examinations, or whether he will train them as chemists, and that the two aims are rapidly becoming mutually exclusive.

The immediate cause of this letter is a question set by a powerful university—shall we call it the University of "A" ?—in a chemistry paper in the last week of November. The question takes the form of a problem on Victor Meyer's method of determining vapour density. The data supplied are—weight of substance, volume of air displaced (collected over water), temperature of air, height of barometer, and the vapour tension of water at the temperature given.

Now I submit, Sir, that the problem as it stands is insoluble. The candidate is told either too much or too little. If he is intended to apply the vapour tension correction, he must be told the state of the air as regards humidity in the apparatus at the beginning of the determination : the "air" displaced is not air at all, but air plus a certain amount (usually 60–80 per cent. of its saturation value) of water vapour. The vapour tension correction is thus not p, where p is the vapour pressure of water at the temperature of the air, but $(100-x)\,p/100$, where x is the percentage saturation of the air in the laboratory. With $x>50$, which is almost invariably the case, more harm than good is done by applying the full correction.

I find it discouraging, to say the least, after I have trained students to think logically on this subject, to see the old fallacy cropping up again in an examination paper of repute. It will be objected, perhaps, that the treatment expected is that given in all the standard text-books (the new edition of Findlay's "Practical Physical Chemistry" is an honourable exception), and that in any case the point is a minor one. To these I would reply that examiners should be expected to point the way, not to follow in the wake of obsolescent text-books ; and secondly, that the point, though numerically negligible, forms excellent material for logical reasoning on the part of the student, and that we cannot expect him to be capable of clear thinking if his examiners show by their questions that they do not require it.—
I am, Sir, etc., HAROLD HUNTER

OPTICAL ACTIVITY AND POLARITY THEORIES

Sir,—In a letter in your issue of December 5 (p. 1214), Prof. Peacock refers to some suggestions of mine relating to the above subject (*J.C.S.*, 1924, **125**, 1121). He describes my paper as one dealing with *general polar effects* (a description incorrectly attributed to me) and states that the general polar effect of a substituent on optical activity had already been indicated by him in 1914 (*Proc. Chem. Soc.*, **30**, 274).

There is, however, no question of priority on this point. The polarity of a group has for long been associated more or less definitely with its acidic character, and the connexion between the influence of substitution on optical activity and acidity was already being developed at an earlier date by Betti (*Gazzetta*, 1906 onwards). A summary published by this investigator (*Ibid.*, 1923, **53**, 417) contains the rotatory powers of thirty-six derivatives of an optically active base and demonstrates the remarkably close parallel existing in this case between the two properties. I was unaware of the full extent of this work until recently.

On my part, I have attempted to show that the relative change in electrical field following on substitution by simple groups can be deduced from the electronic theory. And that the *polar series* so obtained expresses in certain cases the influence of these groups on optical activity and other properties. From this standpoint a positive group such as NO_2 will displace the rotation in the opposite sense to a negative group such as OH. Further, if the rotation of a benzenoid compound is affected by a positive substituent in the order o > m, H > p, the influence of a negative substituent should be given by p > m, H > o and *vice versa*.

These views are quite distinct from those implied by the phrase "general polar effect" (see also *J.C.S.*, 1924, **125**, 2155, 2156) by which is usually understood the influence of the groups as deduced directly from their effect on acidity (compare Flürscheim, *J.C.S.*, 1909, **95**, 718 ; Robinson, *Ann. Rep.*, 1922, 98). Investigations being carried out in these laboratories appear to confirm the existence of both these effects in optical activity.—
I am, Sir, etc., H. G. RULE

Chemistry Dept.,
University of Edinburgh

PERSONAL AND OTHER ITEMS

Sir William Alexander, who is at present in the United States, has resigned his position as chairman of the British Dyestuffs Corporation, on account of increasing business and political activities. Lord Ashfield, whose activities in connexion with London transport are well known, has resigned his Government directorship of the Corporation to succeed Sir William Alexander as chairman and the Rt. Hon. Sir Alfred Mond has accepted nomination as Lord Ashfield's successor on the board.

Mr. T. V. Barker has been reappointed University Lecturer in Chemical Crystallography at Oxford for a further period of five years.

The Chandler medal, given each year by Columbia University for services to science, has been awarded to Prof. E. C. Kendall, of the University of Minnesota, who isolated the active constituent of the thyroid gland.

Prof. Pascal, of the University of Lille, has presented three pieces of apparatus used by Louis Pasteur to the Columbia University. The apparatus —two flasks and a U-tube—will be placed on view in the Chandler Chemical Museum.

Sir John Wormald has resigned his seat on the Board of Messrs. Mather and Platt, after thirty-six years' connexion with the firm.

The Scottish Society of Arts has awarded a Keith Prize, value £20, to Mr. R. MacLaurin for his paper on "Carbonisation of Coal for Smokeless Fuel and Industrial Gas." An award of £85 was also recommended for C. N. Kemp to continue his X-ray work on coal.

The Chemical Department of the University of Manchester has received a gift, from Miss E. M. Scott, of a portrait of John Dalton.

Dr. J. Reilly, Assistant State Chemist to the Irish Free State, has been appointed professor of chemistry in University College, Cork (National University of Ireland), as successor to Prof. Dixon, M.D.

Dr. E. König, who died on October 29, was the chief chemist of the Höchst Farbwerke and a well-known worker in photo-chemistry. To him was due the development of the Pinachrome and Pinatype processes of colour reproduction, and the production of colour-sensitising dyes such as Pinaverdol and Pinachrome for photographic plates, as well as of the photographic desensitiser Pinacryptol.

Atomic and Molecular Structure

The fourth of a series of public lectures on "Atomic and Molecular Structure" was given on November 26 by Dr. J. D. Main Smith, in the Chemistry Department, Birmingham University. The lecturer outlined a new and comprehensive system of classification for simple and complex, and organic and inorganic compounds generally, and indicated that modern problems of isomerism and optical activity necessitated the classification of compounds according to stereo-chemical conceptions.

It was shown that Werner's co-ordination theory, in which molecules are regarded as spatial complexes consisting of atoms closely bound to a central atom, furnished a comprehensive basis for the general classification of chemical compounds. Four main types of compounds were distinguished characterised by the co-ordination numbers 2, 3, 4 and 6, and no others, each type being divisible into subtypes, according to the maximum number of atoms in a plane, and further subdivided according to whether or not the atoms are or are not in cyclic structures—*i.e.*, whether the central atom is or is not combined with chelate groups. The types were further classified according to the number of chelate groups per central atom, and illustrative examples were drawn from every sort of chemical compound.

The spatial conceptions involved in the classification were shown to afford simple explanations of general and optical isomerism, and it was suggested that optical activity is simply due to the rotation of a plane wave on reflection by atoms, the rotation being in a preferential direction when atoms are arranged asymmetrically.

The co-ordination theory was shown to lead to an exact knowledge of the structure of molecules and the superficial features of the structure of atoms.

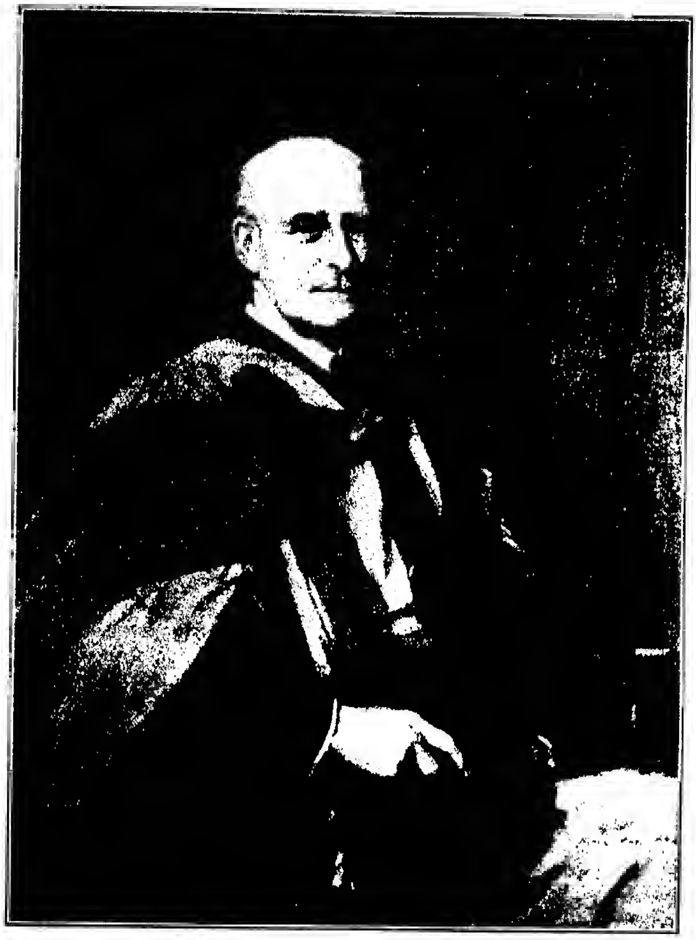
Pulp and Paper in Canada

The preliminary report of the pulp and paper industry for 1923 recently issued by the Forest Products Branch of the Dominion Bureau of Statistics indicates that the industry has made another advance in its recovery from the unsatisfactory conditions three years ago. From the time of its establishment in Canada in 1803, until the post-war depression of 1921, paper-making showed a steady increase. There was a heavy falling-off in 1921, 1922 was a period of readjustment, but with increases in several lines, and 1923 shows a total increase. If the net value of production for the entire pulp and paper industry be considered as the sum of the value of (1) pulpwood exported; (2) pulp made for export, and (3) paper manufactured, then the totals for the years mentioned stand as follows: 1920, \$230,199,717; 1921, \$157,426,587; 1922, \$152,209,711; 1923, \$183,266,218. The total capital investment of \$417,611,678 represented an increase of 9·6 per cent. over 1922. The total number of employees was 29,179, as compared with 25,830 in 1922, and the total pay-roll \$38,305,157 as compared with \$32,918,955. The Province of Quebec maintained the lead on the production of wood-pulp, the value of which was no less than \$50,255,367. This Province also led in the production of paper valued at \$58,566,143.

PRESENTATION OF PROFESSOR SMITHELLS' PORTRAIT TO THE UNIVERSITY OF LEEDS

The presentation to the University of Leeds of the portrait of Prof. Arthur Smithells, C.M.G., D.Sc., F.R.S., who resigned in 1923 the chair of chemistry which he had held in the University and in the Yorkshire College for thirty-eight years, took place on November 25. The chair was taken by Mr. E. George Arnold, Pro-chancellor of the University, and the presentation was made by Mr. A. G. Lupton, treasurer of the Smithells' Fund, who was Pro-chancellor of the University during most of the period of Prof. Smithells' tenure of the chair of chemistry. Prof. Cobb, speaking on behalf of the subscribers to the fund, said it was impossible to enumerate or even to summarise the valuable services which Prof. Smithells had rendered inside and outside the University in so many ways. Even confining himself to University activities it would be impossible to deal with them at all adequately, and to do justice to him, without telling the story of the University, so intimate had been his connexion with all the main features in its development. The record of Professor Smithells as the head of the chemical department of the University, which had grown so much under his care, was one of which any man might be proud.

luates were doing excellent work all over the and its reputation had gone steadily upwards. s work had meant much more than all that. s a great step forward when it was decided to ve no stone unturned in making Leeds a centre of niversity education, but it was important to bear n mind that what was done at that time was not imply to institute another University, but a new ind of University, in which not only should science munity and to the University also. It had meant bringing together people who, unfortunately, had too much come to regard themselves as having very little in common, and to do it thoroughly required the exercise of very special gifts in dealing with men and affairs. It had, however, been done, and the story of this achievement could not be told without prominence being given to the great part played in this development by Prof. Smithells. No one had



By Fiddes Watt, R.A.

Prof. A. Smithells, C.M.G., D.Sc., F.R.S.

ave a place of honour but where a Faculty of Technology should be included, ranking along with Arts, cience and Medicine, and living in closest union ith them. This was based upon an essentially new lea that the principles operative in industrial processes so important in this country, could be made fitting subjects for university study, training, and research, if they were only treated in the proper way. It was a bold policy and made the institution of the University very much of a pioneering venture, but its success had meant much to the industrial com- spoken more strongly, however, than Prof. Smithells himself on the importance of the lay element in the University. In closing, Prof. Cobb spoke of the unique position that Prof. Smithells had held in the University for so many years in relation to the staff and Students. Nobody, he thought, had been the repository of more confidences. Nobody had been so much called upon for advice or had been at more pains to give it to the best of his ability, drawing upon a rare faculty of judgment and a wealth of experience for the purpose.

REVIEWS

Stickstoffindustrie. By Bruno Waeser. (Technische Fortschrittsberichte, Band V). Pp. viii+128. Dresden and Leipzig: Theodor Steinkopff, 1924. Price 4 marks.

Dr. Waeser's small monograph gives a condensed and useful account of the present position of the Nitrogen Industry, including Chile nitre and by-product ammonia. It is mainly a series of brief abstracts, with fairly complete references to the literature and to patent specifications, with useful statistics, and presents a large amount of information in small compass. The index is too brief to be really useful. The information given in the book does not go beyond what is already known in this country, but one or two points of interest may be noted. There has been no production of importance by the Haüsser process, and the processes of Burkheiser and Feld for the recovery of sulphur in gas by conversion into ammonium sulphate, after long runs on large scale operation, have given no important results. The Polzenius method for the production of cyanamid is used only to a very limited extent. Cement can be made satisfactorily from cyanamid mud. Attention is directed to the estimated loss of 600,000 tons of potassium nitrate annually in Chile. The synthetic production of ammonia is well treated, and the results of the Claude, Casale, and Fauser processes are given. To those who have not kept in touch with the important developments in nitrogen fixation since the war, Dr. Waeser's book will be found useful. J. R. Partington

The Enlarged Callender Steam Tables. By Prof. H. L. Callender. Pp. 80. London: Edwin Arnold and Co., 1924. Price 7s. 6d. net.

The publication of this neat and well-printed edition of Prof. Callender's Steam Tables, now extended in Fahrenheit units to 2000 lb. per square inch pressure, and with superheat up to 1000° F. temperature, is an indication of the enormous advances that have been made in the science of steam generation during the past few years. The ordinary steam tables hitherto available in Great Britain have generally ceased at about 250 lb. per square inch absolute because there was no use for further data, and until quite recently the maximum power station conditions were about 200 lb. gauge pressure and 600° F. superheat temperature, most chemical works, for example, using at the present time less than 160 lb. To-day 350 lb. and 700° F. is comparatively common practice for super stations, the North Tees station is working at 475 lb., the Crawford Avenue station at Chicago, now being completed, will be 550 lb., and several experimental boilers both in the United States and Germany are built for 800—1200 lb. gauge pressure.

Further, the "Atmos" boiler of Blomquist in Sweden works at 1500 lb., so that much enlarged steam tables are imperative. It seems a pity, however, that the present book of Prof. Callender's, excellent though it is, stops short at 2000 lb. and is restricted to the Fahrenheit figures only. The "Benson" coil steam generator, for example, operates at 3200 lb. pressure, that is the actual "critical" temperature, and in order to study such conditions the British engineer or chemist has still to purchase American or German steam tables. However, it is understood that Prof. Callender is prepared to extend his book and to add the centigrade figures when there is "sufficient demand to justify publication." It is to be hoped, therefore, this will be forthcoming, for the present volume is certainly a necessity on the shelves of a very wide circle of technical readers and students, especially as the figures given for saturated steam are extended to a vacuum of 29·5 in. with 0·05 in. divisions for the lower figures.

COMPANY NEWS

POWER-GAS CORPORATION

The report for the year ended September 30, 1924, states that a substantial volume of orders has been obtained, especially towards the end of the year, the financing of which, together with the settlement of liabilities for taxation, make it advisable that the resources of the company should be conserved. The profit, after crediting the amount transferred from taxation reserve, was £12,198 (£14,197 last year), which, together with £11,070 brought in, makes £23,268. The sum of £2000 has been placed to reserve, carrying forward £21,268.

PEACHEY LEATHER PRODUCTS, LTD.

The Rt. Hon. Lord Daryngton, P.C., presided over the first ordinary general meeting of this company which was formed in 1923 to work the Peachey process for the cold vulcanisation of rubber. Although there had been some delay in completing the plant, the works were fully employed early this year, producing between 1500 to 2000 yards per day of leather cloth. The decision not to place any material on the market until a large stock in all colours and qualities was accumulated had proved unwise, as the requirements of the market should have been fully tested first. The want of uniformity in the material was thought to be due largely to the use of too large a vulcaniser, and it was found that the vulcanising process then operating had a weakening effect of a serious nature upon the fabric backing. It was therefore decided to discontinue sales until that defect had been eliminated. They had sufficient raw materials in stock to las for from four to six months, and although it w impossible to state what their requirements won be, they did not expect to be in full production the next few months. Samples of the experiment product had been shown to many leading fir and the company were satisfied with the recept given to their material and were confident that th sales would develop with considerable rapidi Agents were in every country in the world ready to push the sale of their products when the improvements had been completed. The major difficulties had now been solved, and an early production of the standard lines of manufacture, which would compete favourably with any other leather cloth on the market, might soon be expected. In order

ilise the space in their works not required for nanufacture of their basic product, the company in negotiation for the manufacture, of side-s, including overshoes for Shoemacs, Ltd., and uring of proofed fabrics for the Textile Company.

PAN DE AZUCAR NITRATE CO., LTD.

The twenty-third annual general meeting took place on November 27, the Rt. Hon. Lord Hunsdon (chairman) presiding. The accounts for the year under review showed a gross profit of £39,162. The sum of £10,472 was debited for depreciation, £4000 reserved for taxes and London expenses and sundry charges came to £4372, of which £1667 was for interest on the purchase price of new grounds, acquired by the company in February, 1924. The net profit was £20,317, which, together with £30,492 brought forward from last year makes a total of £50,809. The results for the year's working were considered satisfactory, and the dividend of 20 per cent. for the year was 5 per cent. in excess of that paid in any of the three previous years. Results obtained from the new grounds were fully up to expectation, and the investment was of considerable value. Co-operation in propaganda was urged between makers of all nitrogenous products. There was a slight improvement in the trade in nitrate of soda, the world's consumption for the year to June 30, 1924, being 2,190,000 t., against 2,160,000 t. for the previous year and 1,545,000 t. for 1922. Sales for the current year had been satisfactory so far, the Producers' Association having sold 1,830,000 t. for shipment from July 1, 1924, to May 31, 1925. Future prospects were considered satisfactory, although it should be remembered that there was likely to be a considerable increase in the output of sulphate of ammonia, both from synthetic plants and as a by-product, but the world demand for fertilisers could be expected to increase considerably as time went on, and it was not improbable that the whole production of nitrogenous substances would be needed.

LONDON NITRATE CO.

A final dividend has been recommended of 12½ per cent., tax free, making 20 per cent., tax free, for the year, compared with 12½ per cent. for 1922–23. It is proposed to place £50,000 (against £30,000) to reserve for redemption of debentures, leaving 11,992 to be carried forward, compared with 16,418 last year.

CONSETT IRON CO.

An interim dividend of 6d. per share on the linary shares, less tax, has been declared, as com-ed with 6d. per share in December last, which paid tax free, the full dividend for the year lling 7½ per cent. In October last a further 1,000,000 six per cent. debenture stock was placed, ranking at the same rate with existing stock of £1,500,000.

MIDLAND BANK LIMITED

The Midland Bank, Ltd., announces that Mr. A. T. Jackson, formerly an assistant general manager, has been appointed a joint general manager.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech. ..	£21 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder..	£47 per ton.
Acid Hydrochloric ..	3s. 6d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali.. ..	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder ..	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime ..	£7 10s. per ton, packages extra.
Borax, Commercial—	
Crystal..	£25 per ton.
Powder..	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride (Solid)..	£5 12s. 6d. to £5 17s. 6d. per ton, carriage paid.
Copper Sulphate	£25 per ton.
Methylated Spirit 64 o.p.—	
Industrial	2s. 7d.—2s. 11d. per gallon, according to quantity.
Mineralised	3s. 8d.—4s. per gallon, according to quantity.
Nickel Sulphate	£38 per ton d/d. Normal business.
Nickel Ammon. Sulphate	£38 per ton d/d. Normal business.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate ..	5¾d. per lb.
Potass. Chlorate.. ..	3d.—4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake..	£3 10s. per ton d/d.
Soda Caustic, solid ..	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5—£5 5s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate (refined)	£10 10s. per ton, carr. paid.
Sod. Bichromate.. ..	4½d. per lb.
Sod. Bisulphite Powder 60/62%..	£17—£18 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. solid 60/65	About £15 per ton d/d.
Sod. Sulphide cryst. ..	£9 5s. per ton d/d.
Sod Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	6¼d.—1s. 2d. per lb., according to quality.

Antimony sulphide—
Crimson .. .. 1s. 4d.—1s. 6d. per lb., according to quality.
Arsenic, Sulphide, Yellow 1s. 11d. per lb.
Barytes .. .. .. £3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide .. 3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide .. £30—£33 per ton, according to quantity.
Carbon Black .. .. 7d.—7½d. per lb. ex wharf.
Carbon Tetrachloride .. £60—£65 per ton, according to quantity, drums extra.
Chromium Oxide, green .. 1s. 3d. per lb.
Indiarubber Substitutes White and Dark .. 5d.—9½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black .. .. £48 per ton, barrels free.
Lead Hyposulphite .. 7½d. per lb.
Lithopone, 30% .. .. £22 10s. per ton.
Mineral Rubber "Rubpron" .. .. .. £16 5s. per ton f.o.r. London.
Sulphur .. .. .. £10—£12 per ton, according to quality.
Sulphur Precip. B.P. .. £50—£65 per ton, according to quantity.
Sulphur Chloride .. 4d. per lb., carboys extra.
Thiocarbanilide .. .. 2s. 6d. per lb.
Vermilion, pale or deep .. 5s. 1d. per lb.
Zinc Sulphide .. .. 7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—
Brown .. .. .. £11 5s. per ton, and upwards.
Grey .. .. .. £14 10s.—£15 per ton. Firmer.
Liquor .. .. .. 9d. per gall. 32° Tw.
Charcoal .. .. .. £7 5s.—£9 per ton, according to grade and locality. Demand brisker in many localities.
Iron Liquor .. .. 1s. 7d. per gall. 32° Tw.
1s. 2d. ,, ,, 24° Tw.
Red Liquor .. .. 10d.—1s. per gall. 14/15° Tw.
Wood Creosote .. .. 2s. 9d. per gall. Unrefined.
Wood Naphtha—
Miscible .. .. 4s. 9d. per gall. 60% O.P.
Solvent .. .. 5s.—5s. 3d. per gall. 40% O.P. Firmer.
Wood Tar .. .. £4 10s.—£5 10s. per ton. Demand slack and stocks being held.
Brown Sugar of Lead .. £42 per ton. Steady market.

TAR PRODUCTS

Acid Carbolic—
Crystals .. .. 5¾d.—6d. per lb. Quiet.
Crude 60's .. .. 1s. 7d.—1s. 9d. per gall. Market quiet but fairly steady.
Acid Cresylic, 97/99 .. 1s. 11d.—2s. 1d. per gall. Fair business.
Pale 95% .. .. 1s. 8d.—1s. 11d. per gall. Not much business.
Dark .. .. .. 1s. 7d.—1s. 9d. per gall. Market dull.
Anthracene Paste 40% .. 4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—
Strained .. .. 6½d.—7½d. per gall. Small demand
Unstrained .. .. 6d.—6½d. per gall.
Prices advanced; supplies very scarce.
Benzole—
Crude 65's .. .. 9d.—11½d. per gall. ex works in tank wagons.
Standard Motor .. 1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure .. .. .. 1s. 9½d.—1s. 11d. per gall. ex works in tank wagons.

Toluole—90% .. .. 1s. 5½d.—1s. 7d. per gall. inquiry.
Toluole—Pure .. .. 1s. 7d.—1s. 9d. per gall. Steady demand.
Xylol—Coml. .. .. 2s. 3d. per gall.
Pure .. .. 3s. 3d. per gall.
Creosote—
Cresylic 20/24% .. 8d.—8½d. per gall. More inquiry.
Middle Oil .. .. } 5½d.—6½d. per gall., according to quality and district. Market firmer. Steady demand.
Heavy Oil .. .. }
Standard Specification }
Naphtha—
Solvent 90/160 .. 1s. 3d.—1s. 4d. per gall. Demand good. Higher prices probable.
Solvent 90/190 .. 11½d.—1s. 1d. per gall. Demand maintained.
Naphthalene Crude—
Cheaper in Yorkshire than Lancashire. Demand rather better.
Drained Creosote Salts £3—£5 per ton. Steady but quiet.
Whizzed or hot pressed £6—£9 per ton. No business.
Naphthalene—
Crystals and Flaked .. £12—£15 per ton, according to district.
Pitch, medium soft .. 47s. 6d.—60s. per ton, according to district. Plenty of inquiry. Prospects brighter.
Pyridine—90/160 .. 18s. 6d.—19s. per gall. Steady business.
Heavy .. .. 11s. 6d.—12s. per gall. Steady.

INTERMEDIATES AND DYES

Business in dyestuffs has been maintained but without further improvement.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 7d. per lb. naked.
Acid H. .. .. .. 3s. 10d. per lb. 100% basis d/d.
Acid Naphthionic .. 2s. 2d. per lb. 100% basis d/d.
Acid Neville and Winther 5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech. .. 1s. 1d. per lb. Good demand.
Acid Sulphanilic .. 9d. per lb. 100% basis d/d.
AluminiumChloride, anhyd. 10d. per lb. d/d.
Aniline Oil .. .. 8d. per lb. naked at works.
Aniline Salts .. .. 8½d. per lb., naked at works.
Antimony Pentachloride 1s. per lb. d/d.
Benzidine Base .. .. 3s. 10d. per lb. 100% basis d/d.
Benzyl Chloride 95% .. 1s. 1d. per lb.
p-Chloraniline .. .. 3s. per lb. 100% basis.
p-Chlorphenol .. .. 4s. 3d. per lb. d/d.
o-Cresol 29/31° C. .. 3½d.—4d. per lb. Easier.
m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline .. .. 2s. 3d. per lb.
Dichloraniline S. Acid .. 2s. 3d. per lb. 100% basis.
p-Dichlorbenzol .. .. £85 per ton.
Diethylaniline .. .. 4s. 3d. per lb. d/d., packages extra, returnable.
Dimethylaniline .. .. 2s. 2½d. per lb. d/d. Drums extra.
Dinitrobenzene .. .. 9d. per lb. naked at works.
Dinitrochlorbenzol .. £84 10s. per ton d/d.
Dinitrotoluene—48/50° C. 8d.—9d. per lb. naked at works.
66/68° C. 1s. 2d. per lb. naked at works.
Diphenylamine .. .. 2s. 10d. per lb. d/d.
G. Salt. .. .. .. 2s. 3d. per lb. 100% basis d/d.
Monochlorbenzol .. .. £63 per ton.
α-Naphthol .. .. 2s. 4d. per lb. d/d.
β-Naphthol .. .. 1s. per lb. d/d.
α- Naphthylamine .. 1s. 3½d. per lb. d/d.
β-Naphthylamine .. 4s. per lb. d/d.
m-Nitraniline .. .. 4s. 2½d. per lb. d/d.

…aniline	2s. 2½d. per lb. d/d.
…obenzene	5¼d.—5½d. per lb. naked at works.
…-Nitrochlorbenzol	2s. 3d. per lb d/d.
Nitronaphthalene	10d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s., per lb. d/d.
p-Phenylene Diamine	10s. per lb. 100% basis d/d.
R. Salt	2s. 4d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 2d. per lb. 100% basis d/d.
o-Toluidine	10d. per lb. naked at works.
p-Toluidine	2s. 10d. per lb. naked at works.
m-Toluylene Diamine	4s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	£45 per ton, ex wharf London, in glass containers.
Acid, Acetyl Salicylic	3s. 1d.—3s. 3d. per lb., according to quantity. Sales steady. Price firm.
Acid, Benzoic B.P.	2s. 6d. per lb.
Acid Boric B.P.	Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 3½d.—1s. 5d. per lb., less 5%. Increased demand.
Acid, Gallic	2s. 9d. per lb. for pure crystal in cwt. lots. Easier.
Acid, Pyrogallic, Cryst.	7s. per lb. Resublimed quality 8s. per lb. Market firm.
Acid Salicylic	1s. 6d.—1s. 7d. per lb., according to quantity.
Acid, Tannic B.P.	2s. 10d. per lb. Quiet steady demand.
Acid, Tartaric	1s. per lb., less 5%.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 10d.—2s. per lb. More enquiry.
Amidopyrin	14s. 6d. per lb.
Ammon. Benzoate	3s. 3d.—3s. 9d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	13s. 9d. per lb. Slightly lower. Quiet steady demand.
Benzonaphthol	5s. 3d. per lb. spot.
Bismuth Carbonate	8s. 6d.—10s. 6d. per lb.
" Citrate	8s. 6d.—10s. 6d. "
" Salicylate	8s. 0d.—10s. 0d. "
" Subnitrate	7s. 7d.—9s. 7d. " According to quantity. Prices recently reduced.
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	Market very firm. Prices uncertain.
Ammonium	2s. 1d. per lb.
Potassium	1s. 10d. per lb.
Sodium	1s. 11d. per lb.
Calcium Lactate	1s. 6d.—1s. 8d. per lb., according to quantity. Fair demand and steady market.
Chloral Hydrate	4s. per lb.
Chloroform	2s. 6d. per lb. for cwt. lots.
Formaldehyde	£48—£49 per ton in barrels, ex wharf London. Supplies exceed demand.
…phosphates—	Fair business passing.
…m, soluble and	
…e free	7s. per lb.
…	8s. 9d. per lb.
Glycerophosphates—	
Magnesium	9s. per lb.
Potassium, 50%	3s. 6d. per lb.
Sodium, 50%	2s. 6d. "
Guaiacol Carbonate	9s. 6d. per lb.
Hexamine	3s. per lb. for bold crystal. Powder slightly less.
Homatropine Hydrobromide	25s.—30s. per oz.
Hydrastine hydrochlor	English make offered, 120s. per oz.
Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. "
Iron. Ammon. Citrate B.P.	1s. 11d.—2s. 3d. per lb. Price recently reduced.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Light, pure	£46 per ton.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£25 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	57s. per lb. for December delivery.
Synthetic	26s.—35s. per lb., according to quantity. English make. Increasing demand.
Mercurials	Market very quiet.
Red oxide	5s. 2d.—5s. 4d. per lb.
Corrosive sublimate	3s. 5d.—3s. 7d. "
White precip.	4s. 6d.—4s. 8d. "
Calomel	3s. 10d.—4s. "
Methyl Salicylate	1s. 9d.—2s. per lb.
Methyl Sulphonal	22s. 6d. per lb. Slightly weaker.
Metol	11s. per lb. British make.
Paraformaldehyde	2s. 8d. per lb. for B.P. quality.
Paraldehyde	1s. 2d.—1s. 6d. per lb. in free bottles and cases.
Phenacetin	5s. 6d. per lb.
Phenazone	6s. 10d. per lb.
Phenolphthalein	5s. 6d. per lb. for cwt. lots. Supply exceeds demand.
Potass. Bitartrate—99/100% (Cream of Tartar)	84s. per cwt., less 2½% for ton lots.
Potass. Citrate	1s. 10d.—2s. 2d. per lb.
Potass. Ferricyanide	1s. 9d. per lb. Quiet.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Steady market.
Potass. Metabisulphite	7½d. per lb., 1-cwt. kegs included. F.o.r. London.
Potass. Permanganate	7½d. per lb. spot. Forward prices higher.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. per lb. in fair quantities. Supplies exceed demand.
Saccharin	63s. per lb., in 50-lb. lots.
Salol	3s. 6d. per lb. for cwt. lots Slightly lower. Limited demand
Silver Proteinate	9s. per lb. for satisfactory product, light in colour.
Sod. Benzoate, B.P.	2s. 6d. per lb. Supplies of good quality now available.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite—	
Photographic	£13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash. according to quantity.

Sod. Nitroprusside	16s. per lb.	
Sod. Potass. Tartrate (Rochelle Salt)	75s.—82s. 6d. per cwt., according to quantity. **Quiet market.**	
Sod. Salicylate	Powder 2s. 1d.–2s. 3d. per lb. Crystal at 2s. 2d.–2s. 4d. per lb. Flake 2s. 6d. per lb. Strong demand. Market firm.	
Sod. Sulphide—		
Pure recryst.	10d.—1s. 2d. per lb.	
Sod. Sulphite, anhydrous	£27 10s. per ton, minimum 5-ton lots, increasing according to quantity, 1-cwt. kegs included.	
Sulphonal	14s. 6d. per lb. Little demand.	
Thymol	18s. per lb. Firmer market.	

PERFUMERY CHEMICALS

Acetophenone	11s. 3d. per lb.	
Aubepine	13s. 6d. "	
Amyl Acetate	3s "	
Amyl Butyrate	6s. 6d. "	
Amyl Salicylate	3s. 3d. "	
Anethol (M.P. 21/22° C.)	4s. 6d. "	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 9d. "	
Benzyl Alcohol free from Chlorine	2s. 9d. "	Again cheaper.
Benzaldehyde free from Chlorine	3s. 3d. "	
Benzyl Benzoate	3s. 6d. "	
Cinnamic Aldehyde—		
Natural	18s. 6d. "	
Coumarin	17s. 9d. "	Again cheaper.
Citonellol	20s. "	Again dearer.
Citral	8s. "	
Ethyl Cinnamate	12s. 6d. "	
Ethyl Phthalate	3s. "	
Eugenol	10s. 6d. "	
Geraniol (Palmarosa)	33s. 6d. "	
Geraniol	12s. 6d.—20s. per lb.	
Heliotropine	6s. 9d. per lb.	
Iso Eugenol	16s. "	
Linalol ex Bois de Rose	26s. "	
Linalyl Acetate	26s. "	
Methyl Anthranilate	10s. "	
Methyl Benzoate	5s. "	
Musk Ambrette	50s. "	
Musk Xylol	14s. "	
Nerolin	4s. 6d. "	
Phenyl Ethyl Acetate	15s. 6d. "	
Phenyl Ethyl Alcohol	16s. "	
Rhodinol	50s. "	Again cheaper.
Safrol	1s. 10d. "	
Terpineol	2s. 4d. "	
Vanillin	25s. 6d. "	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.	
Aniso Oil	2s. 10d. per lb.	
Bergamot Oil	15s. 6d. per lb.	
Bourbon Geranium Oil	30s. per lb.	Again cheaper.
Camphor Oil	65s. per cwt	
Cananga Oil Java	11s. 3d. per lb.	
Cassia Oil, 80/85%	9s. 9d. per lb.	
Cinnamon Oil, Leaf	6½d. per oz.	
Citronella Oil—		
Java 85/90%	7s. per lb.	
Ceylon	3s. 4d. per lb.	Again cheaper.
Clove Oil	8s 3d. per lb.	
Eucalyptus Oil 70/75%	2s. 2d. per lb.	
Lavender Oil—		
French 38/40% Esters	35s. per lb.	
Lemon Oil	3s. 2d. per lb.	
Lemongrass Oil	5s. 9d. per lb.	
Orange Oil, Sweet	11s. per lb.	
Otto of Rose Oil—		
Bulgarian	42s. 6d. per oz.	
Anatolian	28s. per oz.	
Palma Rosa Oil	17s. per lb.	
Petitgrain Oil	9s. 9d. per lb.	
Sandal Wood Oil—		
Mysore	26s. 7d. per lb	
Australian	18s. 6d. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before Feb. 3rd, they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on Dec. 18th.

I.—Applications

Farbwerke vorm. Meister, Lucius, und Bruning. Calcining etc. furnaces. 28,114. Nov. 24. (Ger., 29.11.23.)

Farbwerke vorm. Meister, Lucius, und Bruning. Calcining etc. furnaces. 28,465. Nov. 27. (Ger., 18.1.24.)

Imray (International Combustion Engineering Corp.). Pulverising and drying of materials. 28,602. Nov. 28.

McLeod. Recovery of solid constituents from liquids. 28,537. Nov. 28.

Norrie. Filtering-apparatus. 28,260. Nov. 25.

Perkins. Grinding-oills. 28,590. Nov. 28.

Perry. Apparatus for cooling and filtering air and gases. 28,648. Nov. 29.

Rigby. Drying. 28,381. Nov. 27.

I.—Complete Specifications Accepted

18,817 (1923). Empson. Centrifugal purifying and dehydrating apparatus. (224,935.)

21,273 (1923). Obermiller. Method of giving to air or other gases a definite moisture content. (202,993.)

21,385 (1923). Reid. Furnaces. (224,965.)

12,314 (1924). Nagel. Filtering-devices. (216,167.)

II.—Applications

Heneage. Apparatus for distillation of lignites etc. 28,570. Nov. 28.

Illingworth Carbonization Co., Ltd., and Illingworth. Carbonisation of coal. 28,463. Nov. 27.

Illingworth Carbonization Co., Ltd., and Illingworth. Treatment of coal and coke. 28,464. Nov. 27.

Jones and Parker. Vertical retorts. 28,484. Nov. 27.

Laing and Nielsen. Purification of carbonaceous materials etc. 28,468. Nov. 27.

Marecsche. Manufacture of artificial fuel. 28,387. Nov. 27. (Fr., 8.9.24.)

Schlesisches Kohlenforschungsinstitut der Kaiser-Wilhelm Ges. Method of purifying oils. 28,448. Nov. 27. (Ger., 11.12.23.)

With. Manufacture of coal briquettes etc. 28,490. Nov. 28.

II.—Complete Specifications Accepted

21,082 (1923). Dvorkovitz. Apparatus for making water-gas. (224,950.)

24,440 (1923). Wollaston. Gasification of coke breeze and the like. (225,008.)

3379 (1924). Hinselmann. Obtaining valuable substances from fuels, oil-shale, etc. (217,174.)

III.—Applications

Billinghamo. Emulsification of tar, bitumen, etc. 28,395. Nov. 27.

Lomax, Lucas, and V. L. Oil Processes, Ltd. Methods of separating phenols. 28,138. Nov. 24.

III.—Complete Specification Accepted

6608 (1924). Rütgerswerke Akt.-Ges. Decreosoting of tar and tar-oils. (213,249.)

IV.—Complete Specifications Accepted

295 (1924). Soc. of Chemical Industry in Basle. Manufacture of intermediate products and dyestuffs of anthraquinone and anthracene series. (210,413.)

1306 (1924). Farbenfabriken vorm. F. Bayer und Co. Manufacture of lakes. (216,486.)

710 (1924). Holliday and Co., Ltd., Clayton, and Stokes. Yellow colouring-matter of the pyrazolone series. (225,097.)

V.—Applications

Akt.-Ges. fur Anilin-Fabrikation. Treatment of artificial threads. 28,375. Nov. 26. (Ger., 30.11.23.)

Case, Garrow, and Novocretes, Ltd. Method of treating fibrous materials. 28,672 and 28,673. Nov. 29.

Crosfield. Manufacture of paper etc. 28,284. Nov. 26.

Deutsche Gasglühlicht Auer Ges. Manufacture of solutions from cellulose etc. 28,574. Nov. 28. (Ger., 29.11.23.)

Soc. de Stéarinerie et Savonnerie de Lyon, and Berthon. Manufacture of soluble cellulose esters. 28,576. Nov. 28.

V.—Complete Specifications Accepted

18,666 (1923). Lilienfeld. Process for improving cotton. (216,476.)

12,797 (1924). Stevenson. Manufacture of artificial silk from viscose. (225,135.)

VI.—Applications

Colloisil Colour Co., Ltd., and Eberlein. Dyeing fabrics 28,660. Nov. 29.

Southcombe. Dyeing and compositions therefor. 28,078. Nov. 24.

VI.—Complete Specifications Accepted

13,445 (1923). British Celanese, Ltd., and Ellis. Dyeing colouring of products made with cellulose acetate. (224,925.)

15,279 (1924). Schlumpf. Machines for treating yarns in hanks with liquid. (218,297.)

VII.—Applications

Crosland. Kiln for calcining lime, cement, etc. 28,409. Nov. 27.

Forrester (International Filter Co.). 28,368. *See* XIX.

VIII.—Applications

Eijssen. Metallisation of porcelain or glass. 28,542. Nov. 28. (Holland, 15.2.24.)

Tams. China body for manufacture of pottery. 28,044. Nov. 24.

IX.—Applications

Crosland. 28,409. *See* VII.

Parker, and Vickers, Ltd. Rotary kilns for burning cement etc. 28,567. Nov. 27.

X.—Applications

Coles. Protection of metallic surfaces. 28,617. Nov. 29.

Haglund. Production of metals and alloys. 28,366. Nov. 26.

Johannsen. Treatment of ores etc. 28,269. Nov. 25. (Ger., 7.12.23.)

Marino. Process for de-tinning iron etc. 28,256. Nov. 25.

Metals Production, Ltd., Moulden, and Taplin. Heat-treatment of copper ores. 28,478. Nov. 27.

Penkert. Welding aluminium etc. 28,446. Nov. 27. (Ger., 12.12.23.)

X.—Complete Specifications Accepted

13,036 (1923). Edwards. Treatment of tin ores, concentrates, etc. (224,923.)

253 (1923). Mordey. Electromagnetic separation or concentration of minerals. (224,924.)

687 (1923). Wade (Byers Co.). Manufacture of wrought iron and alloys thereof. (224,941.)

21,558 (1923). Smith and Garnett. Magnetic alloys and their application. (224,972.)

26,478 (1923). Masclmeyer. Tilting furnaces for smelting metals. (205,835.)

29,123 (1923). Jones. Anodes for use in electro-plating. (225,052.)

29,477 (1923). Dyson and Sutton. Method of electro-plating aluminium and its alloys. (225,058.)

30,948 (1923). Connelly and Stewart. Metallic coating-composition. (225,072.)

XI.—Applications

Browne. Electric batteries. 28,351. Nov. 26.

Constantin. Electrodes. 28,656. Nov. 29.

XI.—Complete Specifications Accepted

21,558 (1923). Smith and Garnett. *See* X.

29,123 (1923). Jones. *See* X.

29,477 (1923). Dyson and Sutton. *See* X.

XII. Applications

Barnes and Johnstone. Treatment of oleaginous matter. 28,555. Nov. 28.

Metallbank und Metallurgische Ges. Akt.-Ges., and Gensecke. 28,155. *See* XX.

XII.—Complete Specification Accepted

13,763 (1923). Lever Bros., Ltd., and Craig. Refining of oils and fats. (224,928.)

XIII.—Applications

Blumenfeld and Mayer. Preparation of titanium pigments. 28,557 and 28,558. Nov. 28.

Coleman. Luminous paint. 28,234. Nov. 25.

XIII.—Complete Specifications Accepted

21,412 (1923). Chemische Fabrik auf Actien vorm. E. Schering. Manufacture of resin-like products. (202,997.)

23,099 (1923). Whyte. Paint. (225,001.)

1306 (1924). Farbenfabriken vorm. F. Bayer und Co. *See* IV.

XV.—Applications

Neill. Production of glues etc. 28,222. Nov. 25.

Schryver. Manufacture of gelatin. 28,676. Nov. 29.

XV.—Complete Specification Accepted

25,611 (1923). Leather Products (Yorkshire), Ltd., and Hutchinson. Strengthening and waterproofing leather. (225,018.)

XVII.—Complete Specifications Accepted

555 (1924). Vecchis. Extracting sugar from beet. (209,738.)

5510 (1924). Schluter. Production of rice starch. (225,101.)

XIX. Applications

Forrester (International Filter Co.). Base-exchange materials. 28,368. Nov. 26.

Hartley. Dewatering activated sludge. 28,064. Nov. 24.

Rigby. Cereal products. 28,282. Nov. 26.

XX.—Applications

Deutsche Gold- und Silberscheideanstalt vorm. Roessler, and Albert. Production of unsymmetrical arseno-compounds. 28,158. Nov. 24.

Deutsche Gold- und Silberscheideanstalt vorm Roessler, and Albert. Production of derivatives of organic arseno-compounds. 28,589. Nov. 28.

Johnson (Badische Anilin und Soda Fabrik). Manufacture of carbonyl compounds. 28,349. Nov. 26.

Metallbank und Metallurgische Ges. Akt. Ges. and Gensecke. Distillation of fatty acids etc. 28,155. Nov. 24. (Ger. 28.11.23.)

XX.—Complete Specifications Accepted

26,617 (1923). Etablissements Poulenc Frères, and Oechslin. Manufacture of hydroxylated aliphatic arsinic acids. (206,152.)

9590 (1924). Cassella u. Co. Manufacture of an arsenic compound of the aromatic series. (214,628.)

XXII.—Application

Mexco, Ltd., and Scott. Explosives. 28,670. Nov. 29.

XXIII.—Application

Jung. Apparatus for ascertaining composition of gaseous mixtures. 28,120. Nov. 24. (Ger. 29.11.23.)

XXIII.—Complete Specification Accepted

51 (1924). Conick. Pipette. (225,081.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W.1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number :—*Algeria* : Oils, copper, sulphate (591) ; *British India* : Copper (The Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E.1) ; *Chile* : Leather (593) ; *Egypt* : Leather (590) ; Oil, paint, varnish (C.X./1328) ; *Switzerland* : Rubber, asbestos (589) ; *United States* : Cement (592).

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the Dyestuffs (Import Regulation) Act, 1920, made during November has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee.

The total number of applications received during the month was 439, of which 335 were from merchants or importers. To these should be added 12 cases outstanding on November 1, making a total for the month of 451. These were dealt with as follows : Granted, 304 (of which 273 were dealt with within seven days of receipt). Referred to British makers of similar products, 89 (of which 77 were dealt with within seven days of receipt). Referred to reparation supplies available, 23 (all dealt with within two days of receipt). Outstanding on November 29, 1924, 35.

Of the total of 451 applications received, 373 or 83 per cent. were dealt with within seven days of receipt.

Irish Beet Sugar

The British Sugar Beet Society is informed that the Irish Free State Government is prepared to give State assistance to any beet sugar factory scheme operated in that country, on lines which will take into account the entire absence up to the present of experience and education in this new industry. Lord ffrench has consented to act as secretary and take charge of preliminary arrangements for the formation of an Irish society which is already in contemplation.

Tar and Tar Products in Germany

H.M. Commercial Secretary at Cologne reports that the recent revival in business in tar products in Germany is due to the decrease in production which is forcing the distillers to buy from producers who are not bound by contracts and are able to sell tar freely. Prices have increased from 3·50 marks to 5·50 and 6 m. or more per 100 kg., but prices for finished products have not risen, but rather fallen, despite the fact that distillation costs are estimated to be at least one-third of the raw tar price. In East, South and Central Germany stocks of pitch are completely sold out and the oil production is entirely absorbed by the consumers. Business in naphthalene is quiet, but the demand for anthracene for dye manufacture exceeds the production.

PUBLICATIONS RECEIVED

FUEL, SOLID, LIQUID AND GASEOUS. By J. S. S. Brame. Third edition. Pp. xv+388. London : E. Arnold and Co., 1924. Price 18s.

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council of Pure and Applied Chemistry

which consists of Representatives from

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals and the Royal Agricultural Society.

VOL. 43 NEW SERIES LONDON, DECEMBER 19, 1924 NO. 51

EDITORIAL

THIS week the University of Leeds is celebrating with fitting pride and ostentation the fiftieth anniversary of the founding of that small college from which it has developed. Quite recently we recalled in these columns the pioneer work of some of the early professors who laid the foundations of the teaching and research carried on to this day. The Yorkshire College began fifty years ago with three professors and one student and it is recorded that the then professor of physics and mathematics found his first duty was to teach the student how by Euclidean methods to construct an equilateral triangle. The creation of a college involved work quite apart from teaching: the organisation of local enthusiasm, the supply of funds, the acquisition of buildings and other such problems require much time and no little tact. Leeds was fortunate in having a number of public spirited men who put their shoulders to the wheel manfully. The progress of the college and the university has been as steady and as rapid as anyone could wish. When the Society of Chemical Industry meets in Leeds next summer the members will find a flourishing university with well-equipped chemical laboratories, several distinguished professors and lecturers on chemistry and many students. The dyeing department was, and perhaps still is, the best in the world; the department of agricultural chemistry and the experimental agricultural farm have made important contributions to knowledge. The Annual Meeting at Leeds is being well organised and the presence of a considerable body of American engineers will give it unusual interest and importance. Leeds is well suited for such a meeting; it stands on the edge of the industrial district so densely filled with coal-pits and forges that the birds have to fly backwards to keep the soot out of their eyes, and it also stands on the edge of one of the cleanest, most beautiful and picturesque parts of the North of England. Those who wish to visit works can find abundant opportunities; those who like the lonely hills, the bright streams or ruined abbeys and castles famous in history will find much to interest them. Those who know the Dales and have lived there, you would not persuade by all the wealth of Attalus, to trust their sensitive minds to dwell too long on the discordant features of Hunslet and Holbeck. For ourselves we shall worship the sweetly murmuring and sweetly smiling Wharfe!

* * *

The student of history is familiar with the process, which seems invariably to occur after great wars, of taking stock. A prolonged and disastrous interruption of the ordinary course of affairs induces the need, when comparative tranquility is restored, for some general survey of present knowledge, for some indication of tendencies. In science, such phenomena occur as persistently as in political and economic relations. The dispute, unreal to many of the present generation, over the Darwinian theory, led to the reconsideration and revivification of the biological sciences, with results some of which are still to come. A similar state of affairs has harassed the chemist, and under the bombardment of radioactive particles his electrons begin to concern him greatly and questions of co-ordination begin to obtrude themselves with unavoidable persistence. So it has come about that chemistry is undergoing a kind of stocktaking. The private life and behaviour of the most retiring organic compounds are being ruthlessly exposed by our Lowrys and Lapworths. All sorts of fundamental questions, from crystallisation to works costs, are being considered by our chemical engineers. Some of the more daring spirits are trying to acquire new habits of thought in order to grasp the Einstein theory and wondering whether their mathematics will stand the strain. There are many research institutions at work throughout the land, investigating paint and plaster, glass and gelatin, and our energetic president and his predecessor have shown, each in his own way, what chemists must do if they are to be effective as a body. And, of course, many books have been published which add their tribute to the stream of

inquiry. Some of these questions, in fact, as many as time and space would allow, have been discussed in our editorial columns, and, though we are hampered by much modesty, we like to think that some, at least, of our words have not gone unheeded. It is of interest, in our survey, to observe what our regenerated cousins, the physicists, are thinking about, and those who wish to know cannot do better than obtain a little book, "Physics in Industry," which Humphrey Milford and the Oxford University Press publish for the Institute of Physics, at the modest price of three shillings. One of the three lectures given in the book discusses the applications of physics in the ceramic industries, and we cannot resist the temptation to quote: "Chemistry without physics would be a poor subject. Indeed . . . chemistry without physics would be purely descriptive, much like descriptive mineralogy. The invasion of physics has prevented chemistry from developing into an elaborate collection of recipes after the style of a cookery book. The points of contact are said to belong to physical chemistry; physics, or if you like, physical chemistry, is busy revolutionising inorganic and organic chemistry." These are hard words, and a chemist is responsible for them. The lecturer is Dr. Mellor, the author of a Treatise on Inorganic Chemistry which we should call monumental if such a word did not suggest a mason's yard rather than a well-thumbed book. What can be said in reply?

* * *

Prof. G. T. Morgan was in his own home and surrounded by his friends and neighbours, when he took the chair at Birmingham on the occasion of the joint dinner of the local sections of the Society and the Institute. He diffused a feeling of hospitality and friendliness, and his dual position as chairman of both sections emphasised the co-operation which has been gradually springing up during recent years. The Society exists primarily to promote the welfare of applied chemistry, the Institute primarily to promote the welfare of chemists. In these prime factors there is much that is common to both. The residual affinity of the two bodies is considerable, and capable of easy co-ordination. Their induced polarities may alternate and be capable of more than one interpretation, but there is beyond doubt a large sphere of influence outside the primary functions of these bodies, capable of being directed and used for the greater benefit of mankind. The existence of joint dinners, common committees and common chairmen is evidence of this. Mr. Woolcock in his address dwelt briefly on the benefits derived from the exhibition at Wembley. No-one is more competent than he to speak of Wembley. In London recently we have had no days, merely gloomy intervals between nights. It seems to us that our President has now no time in London, he has merely hurried intervals between journeys all over Great Britain. His faith in the Society and the progress it is making spur him from city to city and from section to section. We know that he has this faith and we know it is justified. Such faith must produce something; we know not what will come of it, but are prepared to wait and see.

MODERN ELECTROLYTIC CELLS

By Professor A. J. HALE

(Continued)

Diaphragm Cells. These occupy a prominent position to-day, and most of the large installations in this country, France, Italy and the United States are of this type. The earliest forms, some of which are still in use, were the Hargreaves-Bird (Fig. 20), the Griesheim Elektron, Billiter-Siemens, and the Outhenin-Chalandre cells.

The first has been worked from 1899 and is now in use at Middlewich (also in Austria) for the production of sodium carbonate or caustic soda and chlorine. It was one of the earliest cells and followed by a few years the installation of Elektron diaphragm cells which was started near Frankfurt in 1890.

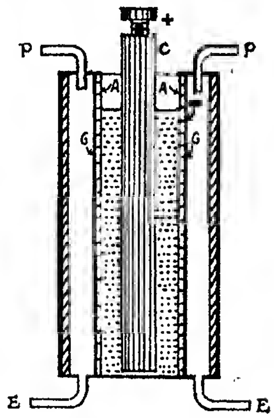

Fig. 20
Hargreaves-Bird Cell

Each Hargreaves cell consists of an iron tank lined with cement and about 10 ft. long, 5 ft. deep, and 2 ft. wide. It is divided longitudinally into three compartments by two asbestos sheet diaphragms, A, each of which is supported on the outer side by a perforated copper sheet which serves as cathode. The centre or anode compartment, which carries a row of graphite anodes, is supplied with brine. During the electrolysis this percolates through the diaphragms, and, as fast as caustic soda is formed on the cathode sheet, it is swept down to the bottom of the outer compartment by steam and carbon dioxide. Since this cell closely resembles recent cells such as the Allen-Moore and Nelson cells for producing caustic soda, there seems no reason why the more valuable product should not be made in the Hargreaves-Bird cell instead of sodium carbonate.

The Griesheim cell (Fig. 21) consists of a steam-jacketed tank, in which cement boxes, each of which contains a magnetite anode, alternate with sheet-iron cathodes. The wall of the tank acts also as a cathode, and therefore the cement boxes containing the anodes act as diaphragms.

The chief installation is at Bitterfeld, in Saxony, where the power, aggregating something like

30,000 h.p., is obtained from the combustion of lignite, which occurs in the locality.

The Billiter-Siemens cell resembles the Billiter-Leykam cell, already described, but a diaphragm constructed of asbestos and barium sulphate is fixed horizontally at the mouth of the bell. The cell was used in installations in Germany and America before 1914, and an improvement in the design was made in 1916 (E.P. 101,440).

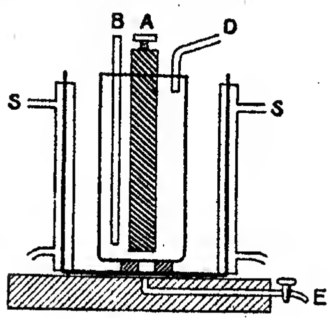

Fig. 21
Griesheim Elektron Cell

The Outhenin-Chalandre cell has been extensively used in France and Switzerland since about 1895, and was extensively used for the production of chlorine during the war. The cell (E.P. 15,906/93), shown in vertical section in Fig. 22, is of earthenware, and is divided into an inner anode and two outer cathode compartments by two vertical partitions, through which pass the porcelain tube diaphragms. The graphite anodes are attached to the positive terminals U, and are situated between the sloping unglazed porcelain tubes, which serve as diaphragms and within which the negative iron lugs project. The porcelain tubes are open at both ends, so that hydrogen passes up into the collecting cathode chamber formed by partition V, whilst the caustic soda liquor formed flows downward to the bottom of the cathode compartment and is drawn off through the pipe V.

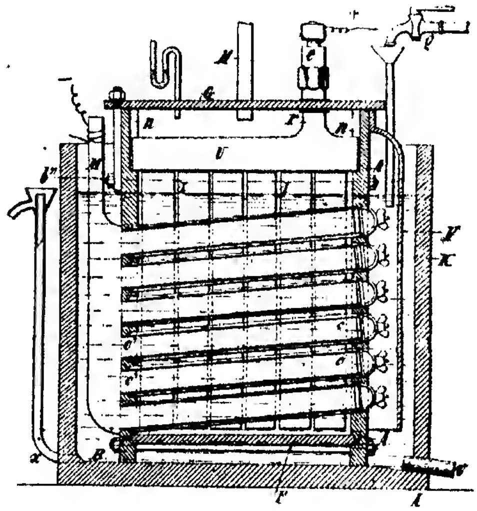

Fig. 22
Outhenin-Chalandre Cell

The more recent diaphragm cells include the Nelson, Allen-Moore, Wheeler, Vorce, and Gibbs cells, the last three of which are cylindrical. The Basle cell is rectangular, but is rather different in design from the rectangular cells already mentioned.

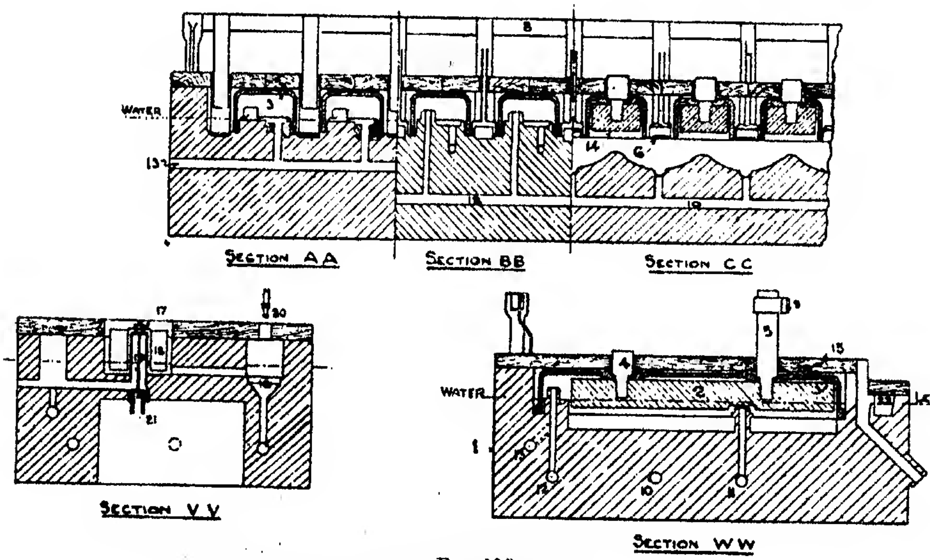

Fig. 19*
Jenkins Bell Cell
* cf. p. 1231 of previous issue for description

All are simple in design and have a high efficiency, and some of them in particular are displacing the older cells in all up-to-date installations.

In considering the merits of the different cells for chlorine and alkali, account must be taken of the facts which appear in the tabular statement given at the end of this section.

A diaphragm will need replacing after six to twelve months of service, its resistance will necessitate a slightly higher voltage than will be required by a bell cell of equal capacity, and the brine must be purified before admission to the cell, otherwise the diaphragm resistance will increase considerably, owing to clogging of the pores. Like bell cells, they give an alkali liquor containing much salt (14 per cent., approximately), which has to be removed during evaporation for solid caustic soda, whereas the caustic liquor obtained from mercury cells is practically free from salt.

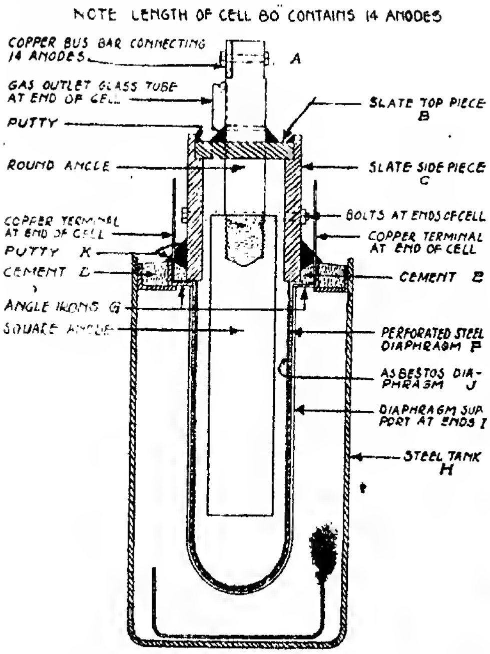

FIG. 23

Nelson Patent Electrolytic Cell

Although mercury cells can be worked at higher current densities (15-20 amperes per sq. dm.), and give more concentrated alkali which is practically free from salt, there are difficulties associated with the proper flow of the mercury in such cells, and the initial cost of mercury, amounting to some thousands of pounds for an average installation, may be reasonably regarded as an unnecessary expenditure.

No bell or gravity cell is as simple in structure as the more simple diaphragm cells, and generally they give a less concentrated caustic liquor. The Nelson cell (U.S.P. [illegible]0/15) is a development of the older MacDonald [illegible] and occupies less floor space than many cells. Each unit (Fig. 23) consists of a steel container in which a perforated U-shaped cathode of steel sheet is welded to supporting angle irons. The asbestos cloth diaphragm is fastened to the inside of the cathode, and internal to this is the anode compartment containing graphite anodes immersed in the brine and supported by a slate gas dome; the ends of the anode compartment are closed by blocks

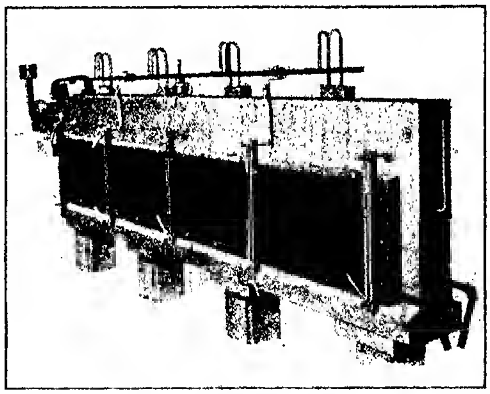

FIG. 24

Allen-Moore Cell

of cement. Steam admitted to the cathode spaces serves to remove the strong caustic soda formed on the electrode, and to maintain the temperature requisite for smooth working. Each cell is about 6 ft. in length and 10 ins. wide. During the European war an installation of Nelson cells at Edgewood Arsenal in America was producing 100 tons of chlorine and the same amount of caustic soda per day.

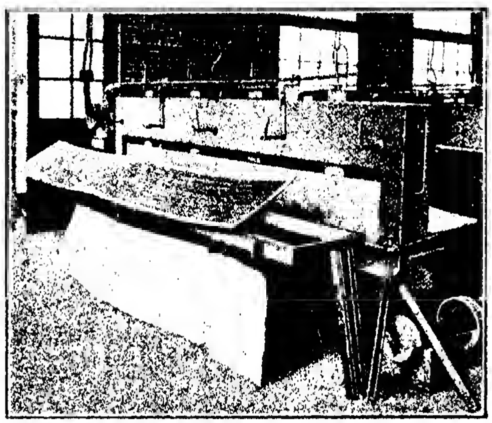

FIG. 25

Allen-Moore Cell

The Allen-Moore cell is similar to the last cell in many respects, and was first installed in America in 1912. It consists of a rectangular framework of reinforced concrete formed by a base, two ends and a top (Figs. 24 and 25). When the long rectangular openings in the side are closed by the diaphragms

and perforated cathode sheets, the interior forms the anode compartment.

The shallow iron side plates when clamped into position keep the cathodes and diaphragms in position, and form cathode spaces on either side of the anode compartment. Such arrangement greatly

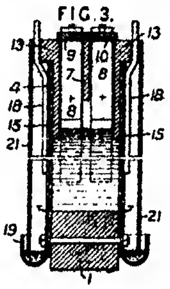

Fig. 26
Cranston and Le Bar Cell

facilitates the changing of diaphragms, when this is necessary, and renders the interior of the cell easily accessible. Brine is admitted to the anode compartment through a hard rubber float-valve, which automatically controls the level of the brine in the compartment, and the graphite anodes are connected to a positive bus bar running along the top of each cell. Caustic soda percolating through the cathodes is removed in an atmosphere of steam and hydrogen by

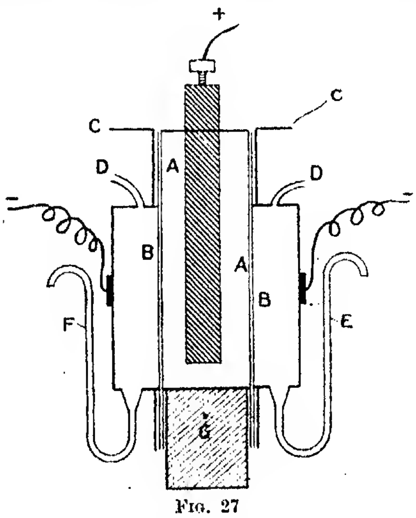

Fig. 27
Townsend Cell

flowing down the face of the cathode plate into the channel trough of the cathode box, whence it leaves by discharge pipes for the caustic soda store tank.

The Marsh cell (U.S.P. 1,443,797/23) is a rectangular diaphragm unit similar to the two just described, but the cathodes of perforated sheet steel are corrugated to conform to the surface of the horizontal graphite anodes, and asbestos paper diaphragms are clamped to the cathodes. Each cell is about 4 ft. long and 1 ft. wide.

A vertical section of a rectangular cell patented by J. Cranston and W. D. Le Bar (E.P. 194,428/21) is shown in Fig. 26. The body portion, 1, is made of slate or concrete in which are suspended graphite anodes, 8. A portion of each side of the body is cut away, and against this part is fixed the diaphragm of asbestos, 15, backed by a perforated metal sheet cathode, the lower end of which is turned up to form a trough, 19, for collecting the caustic liquor formed on the outside of the electrode. The sides, 4, of the upper portion of the cell body extend into the electrolyte to form a sealing wall between anode and cathode chambers, so that chlorine formed in the anode compartment is effectively separated. The

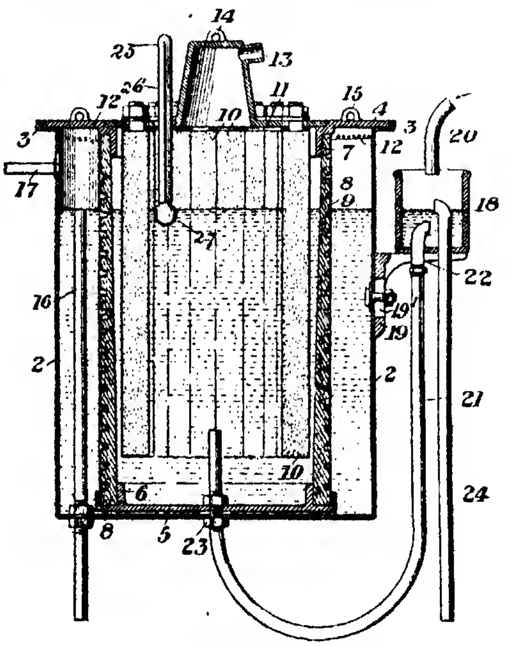

Fig. 28
Gibbs Cell

anodes are inserted through slots separated by partitions, 7, in the top of the body, and are mounted in sets upon metallic plates, 9, 10, forming a gas-tight connexion. A sheet of metal, 21, from the top of the body extends into the trough, 19, and thus forms a sealed chamber for collecting hydrogen. The terminal cathode bars are shown at 18.

The Townsend cell (Fig. 27) has been in use at Niagara since 1905. It resembles the Hargreaves-Bird cell in general structure, also the Allen-Moore cell, but the cathode compartments contain kerosene, which floats on the top of the caustic soda liquor, and the latter overflows through the swan necks, EF. The effect of the oil in contact with the cathode is to cause the caustic soda to form spherical drops, which are rapidly removed from it, thereby falling through the oil to the bottom of the compartment. Each cell is about 8 ft. long, the body consisting of bottom and ends made of cement or concrete, to the foot of which two strong iron plates, CC, forming the outer

containing walls, are clamped. Kerosene supply pipes are shown at DD.

The Gibbs cell (cylindrical diaphragm) is one of the most important of this type, which is the most convenient and most efficient type in use at the present time. Gibbs cell (Fig. 28) is installed at the works of the Pennsylvania Salt Company, United Alkali Company at Widnes, and the Canadian Salt Company, Ontario. The Vorce cell, introduced at about the same time (1907), and the Wheeler cell are similar in construction.

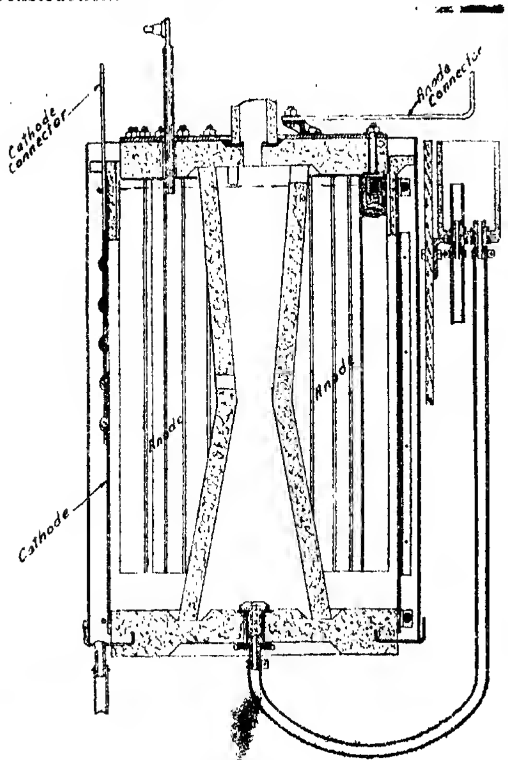

FIG. 29
Wheeler Cell

The outer body of the Gibbs cell is of iron, carbon anodes being fastened to the cover and dome, which form the top of the cell. The diaphragm, which is submerged on both sides, is fastened to a flat annular ring, at the top, which, like the cover, can be easily removed for cleaning and inspection. The cylindrical steel cathode supports the diaphragm, and is covered with a large number of projections which help to support the diaphragm and at the same time serve as points of electrical activity on which highly concentrated caustic soda is formed, and from which it is removed with considerable rapidity, thereby preventing any formation of hypochlorite or chlorate.

The brine feed-cup, 18, serves to maintain a correct level in the cell which is 28 ins. in diameter and 4 ft. high. Such a cell can take 800 amperes at 3·6 volts, and runs with an energy efficiency of 60—62 per cent., which is as high as that of the best cells.

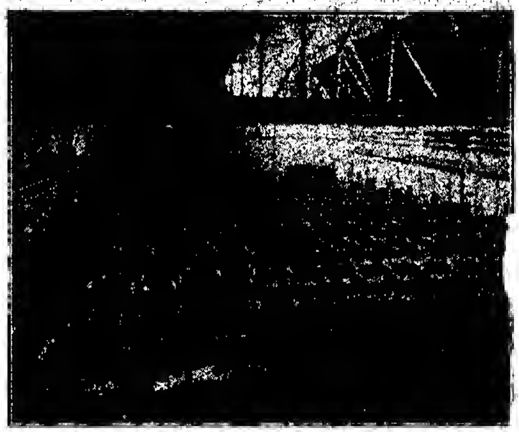

FIG. 30
Installation of Wheeler Cells

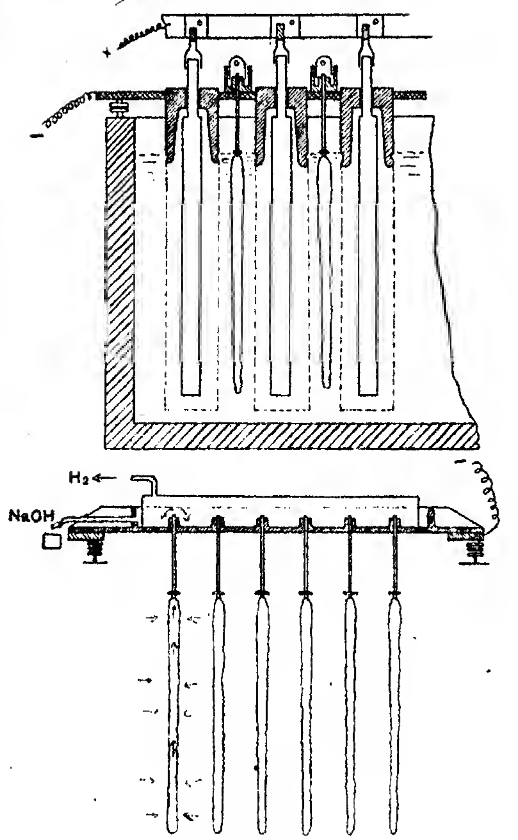

FIG. 31
Cell of the Society of Chemical Industry in Basle

The Vorce cell is cylindrical and is fitted with a circle of graphite anodes in a centre compartment, which is fed from beneath with saturated brine. A 1000-ampere unit is 26 ins. in diameter and 40 ins.

Comparison Table of Efficiencies

Cell	Capacity in amperes	Voltage	Current efficiency	Energy efficiency	Concentration of alkali, g. per litre	Kw.-hrs. per kg. NaOH
Castner mercury	560	4·2	94	50	200	3·4—4
Aussig bell	600	3·6	85	49	80	3·1
Billiter-Siemens	2000	3·1	92	68	120	2·4
Nelson	1000	3·7	90	60	120	2·5
Gibbs	800	3·6	94	60	—	2·5
Basle cell	up to 10,000	—	90	59	—	2·6

high, and the floor space required is approximately 15 sq. ft., as compared with 25 sq. ft. for a Nelson unit, or 60 sq. ft. for an Allen-Moore unit of the same capacity. Its output is 5 lb. of caustic soda per sq. ft. of floor space per day, compared with 2·7 lb. and 1·2 lb. for the Nelson and Allen-Moore cells, respectively.

Its weight is 600 lb., compared with 2500 lb. for the Allen-Moore cell, whilst the weight of graphite anodes are approximately :—Vorce, 214 lb. ; Nelson, 240 lb. ; Allen-Moore, 440 lb.

These figures quoted in favour of the Vorce cell also hold for the Gibbs and Wheeler cells.

The Wheeler cell (Fig. 29) is shown in vertical cross-section. Its similarity to the usual make of cylindrical cell is apparent, and the diaphragm is not submerged on the cathode side. The brine is admitted through the bottom to the centre of the cell and evenly distributed to all parts. Discs of dielectric material form the top and bottom of the cell, that at the bottom being reinforced with a steel trough, which also acts as a collector for the caustic liquor. The cell is stated to operate with a particularly thin asbestos diaphragm, which insures a high efficiency. An installation of Wheeler cells is shown in Fig. 30.

The last diaphragm cell to be described will be that of the Society of Chemical Industry in Basle, which is installed in France, Switzerland and Italy. A rectangular concrete tank (shown in longitudinal and transverse section, Fig. 31), having an area of 50 sq. ft., is filled with brine, whilst graphite anodes and self-propulsive cathodes of iron rod are submerged as indicated. Each cathode rod is encased in asbestos, which terminates at the top in an iron tube, through which a hydrogen and caustic-liquor foam passes to a covered iron channel. The propulsive effect produced by the rising bubbles of hydrogen causes a circulation inwards of the electrolyte, the speed of which depends on the current density at the cathodes. Several such cathodes screwed into a gutter form a cathode unit, the gutter itself being screwed on a frame, which serves as negative conductor. The anode unit consists of a narrow bell made of non-conducting material, into which the carbon anode is fixed, and which has an outlet for chlorine. To the bell an asbestos bag is attached. The anodes and their asbestos diaphragms last about three years. The electrolysers in use at Monthey, Switzerland, have a capacity up to 7000 amperes and produce 240 kg. of caustic soda per twenty-four hours.

(To be continued)

ACADÉMIE DES SCIENCES

On October 20, Prof. H. Le Chatelier read a paper on the variation of the viscosity of glass as a function of the temperature. Within a temperature difference of 500 to 1000° C., the viscosity may vary from 1 to 1 milliard. M. A. Lumière, who had announced in a previous paper that a normal human serum toxic for the guinea pig became harmless when exposed to a vacuum, advanced an explanation according to which the slight flocculation produced by the vacuum sufficed to prevent the toxic shock. M. Lindet presented a note by M. Guittonneau, showing that the Microsiphonaceæ of the soil assimilate with practically the same facility ammoniacal, nitrous and nitric nitrogen. The quantity of combined carbon available as a source of energy determined the utilisation of mineral nitrogen.

On October 27, amongst other papers, there was an interesting one by M. M. Stoklasa and Penkava, on the comparative radio-activity of the air in the potash mines of Alsace, in Vesuvius, and in the Solfatara, showing the influence of radio-activity on the growth of plants and the fixation of atmospheric nitrogen.

On November 17, the Académie heard the funeral oration to Sir Archibald Geikie, a foreign member of the Académie since 1917. A paper by L. Barrabé and P. Viénnot described a discovery of an oil field at Gabian (Hérault). A description was given of the technical and geological considerations which led the authors to select a site for the boring which passed through the upper trias into a region specially favourable for the accumulation of oil. M. Deslandres, discussing band and line spectra, deduced a simple law correlating the radiations of simple bodies. M. Béhal described the work of M. Freundler on the action of light on stannous iodide, showing that the association of iodine, tin and sodium which occurs in sea-water, plays a part in that "dissimilation" of iodine which the author had discovered in Laminariæ at certain periods. A paper by M. Lebeau described the transformation of the diamond into graphite, this change taking place progressively in a vacuum between 1500 and 2000° C. M. Chaussin described the cultivation of wheat with and without fertilisers, and showed that the higher yields obtained with fertilisers correspond (1) to a greater osmotic pressure in the leaf and stem ; and (2) to a much greater value for the ratio of the mineral matter to the total extract in the soluble part of the leaf.

COLLOIDAL PROTECTION*

By JEROME ALEXANDER

Intellectual inertia is, perhaps, the most appropriate term to apply to that attitude of mind which resists the acceptance of truths inconsistent, or apparently inconsistent, with previously-accepted or "classical" ideas of science. In most cases in industry, practical men are far more numerous than chemists and are continually in close contact with actual operating conditions; and in addition to the mere numerical advantage in opportunity for observation thus given, the practical man is usually not handicapped by prior knowledge of what he must see, and what it is unorthodox to observe.

It is for this reason that technical practice frequently is far in advance of theoretical or scientific knowledge. Another reason is that many teachers of chemistry look askance at experimental data which do not fit into the already sufficiently numerous and complicated laws and principles that they must make plain to the coming generation. And, finally, when non-conformist facts stubbornly press their way forward, the attempt is generally made to force them into compliance with existing theories. Thus the purple of Cassius was regarded by Berzelius to be a definite chemical compound, for on precipitation and re-solution it acted as a unit; and for many years it was so accepted. About twenty years ago, however, Zsigmondy proved it to be an adsorption compound by showing that it could be synthesised by simply mixing colloidal gold and colloidal stannic acid; and just recently A. Huber (*Physikal. Zeit.*, 25, 45 (1924)) confirmed Zsigmondy's proof by X-ray analysis, which showed that none of the gold is chemically combined with the tin.

The technical use of what we now call "protective colloids" goes back into the dim mists of antiquity. The Chinese used glue in the manufacture of their ink to deflocculate the lamp-black, just as they also used sheeps' thyroids to aid morons—both worked. And the ancient Egyptians used gum (probably acacia) in their inks for the same reason, and made their clay as workable as that of Babylonia by the use of infusions of straw. The alchemists of the Middle Ages produced their *aurum potabile* by reducing solutions of gold in the presence of stabilising ethereal oils; and at least as early as 1794 silk was dyed with colloidal gold. Berzelius, in his *Lehrbuch* (1844), gives recipes for producing several shades of colloidal gold, and long prior to this, isinglass, egg albumen, and starch were used for the same purpose.

In 1897, just before Zsigmondy (1898), unaware of Faraday's earlier (1856) work with "jelly" as a protector for colloidal gold, had independently rediscovered the phenomena, von Meyer and Lottermoser (*J. prak. Chem.*, 56, 241) recognised the protective action. They drew attention to the fact that albumin stabilises silver sols—a fact well known to practical photographers. In his book "Anorganische Kolloide," p. 50 (1901), Lottermoser said: "On the addition of very stable colloids, such as albumin, gelatin, agar, or gum arabic, to a silver sol, no precipitation is caused by electrolytes until the stable colloid is coagulated. The less stable silver sol is thus protected against the electrolyte by the more stable colloid; it becomes more like it in its behaviour."

To put it tersely, a protector is a substance that opposes the aggregation of molecules or particles into larger groups. It is natural to expect that substances will vary widely in their protective power, if, indeed, they show any protective action at all; and also that a substance which is a protector in one set of conditions, may, under other conditions, show a different degree of protective action, or none at all. To establish some measure of protective action, Zsigmondy determined the number of milligrams of protective substance which would just fail to prevent 10 c.c. of pure colloidal gold solution from changing its colour from red to violet upon the addition of 1 c.c. of 10 per cent. sodium chloride solution. These ruby-red gold sols contain 0·005—0·006 per cent. of gold, and are exceedingly sensitive to traces of electrolytes. The subjoined table gives such "gold numbers" for a variety of substances, taken from the results of Zsigmondy and of Schryver:—

Substance	Gold number
Gelatin	0·005 to 0·01
Russian glue	0·005 to 0·01
Isinglass	0·01 to 0·02
Casein (in ammonia)	0·01
Egg-globulin	0·02 to 0·05
Ovomucoid	0·04 to 0·08
Glycoprotein	0·05 to 0·1
Amorphous egg-albumin	0·03 to 0·06
Crystallised egg-albumin	2·0 to 8·0
Fresh egg-white	0·08 to 0·15
Gum arabic	0·5 to 4·0
Gum tragacanth	2·0±
Dextrin	6·0 to 20·0
Wheat starch	5·0±
Potato starch	25·0±
Sodium oleate	0·4 to 1·0
Sodium stearate at 100 degrees	0·01
Sodium stearate at 60 degrees	10·0
Deutero-albumose	∞
Cane sugar	∞
Urea	∞
Stannic acid sol (old)	∞

The results with sodium stearate indicate that the degree of dispersion of the protector is a very material factor in its action, just as it is in the detergent value of soap, and lends support to the generally-accepted view of Bechhold that protective action is consequent upon the adsorption of a layer of the protector at the interface between the dispersed and the dispersing phase. The thinness of the layer seems obvious from the fact that Zsigmondy could see no diminution of the Brownian motion caused by it, nor any ultramicroscopic evidence of its existence. Since protectors are substances having considerable attraction for water and, as a rule, a great swelling capacity, it is not unlikely that after ordinary desiccation they may swell enough to force the constituent particles of the protected substance far enough apart so that they are beyond the range of molecular attractive forces which is ordinarily estimated to be about 50 $\mu\mu$. But it is not intended

* Paper read before the American Section of the Society of Chemical Industry on May 16, 1924.

to go here into the maze of theoretical discussion—the experimental facts of protection are interesting and suggestive.

A capital instance of the effect of colloidal protection is seen in the case of milk, where the casein, an unstable colloid, is protected or stabilised by lactalbumin. In the older books this relation of the two proteins was obscured by the practice of reporting their sum as "total proteids"; but the [illegible]owing table, based on the averages of Koenig, once shows the great differences between milks, well as the importance of the casein-lactalbumin [illegible]o in determining these differences :—

Average Composition of Various Milks

Kind	Casein	Lactalbumin	Fat	Lactose
Cow	3·02	0·53	3·64	4·88
Woman	1·03	1·26	3·78	6·21
Goat	3·20	1·09	4·78	4·46
Ewe	4·97	1·55	6·86	4·91
Mare	1·24	0·75	1·21	5·67
Ass	0·67	1·55	1·64	5·99

[illegible]xperiment shows that cows' milk is much more [illegible]dily coagulated by acid and by rennin than is [illegible]hers' milk, and that the coagula of mothers' [illegible]k, if formed, are much finer. The addition of [illegible] protector-proteins like gelatin or albumin, [illegible]bohydrates like dextrin, Irish moss, or gum arabic, [illegible] even salts like sodium citrate—will make cows' [illegible]lk behave more like mothers' milk, and will make [illegible] more digestible for the infant. Regarding the [illegible]ghly protected asses milk, so eminent an authority [illegible] A. Jacobi stated as far back as 1888 that it is a [illegible]uge to which the physician flies when neither [illegible]ws' milk nor even mothers' milk is tolerated.

In this connexion it seems probable that any cause [illegible]ich decreases the proportion of lactalbumin to [illegible]ein in mothers' milk—such as nervous shock or [illegible]mia—will tend to register itself in a digestive [illegible]t in the nursing infant. This ratio undoubtedly [illegible]es with the period of lactation as well as in different [illegible], so that the milk of a herd is much more uniform [illegible] that of one cow.

Plural Protection

An outcome of these observations on milk was the [illegible]evelopment of the idea of *double or plural protection*. [illegible]he attempt to produce an imitation of casein by [illegible]rming a precipitate of calcium phosphate in the [illegible]esence of protectors (gelatin, gum arabic) was not [illegible]sful when the protector was added to the phosphate solution or to the calcium solution. On reflection, however, it was evident that in the organism, *both* the reacting solutions contain protectors, and on protecting both the sodium phosphate and the calcium chloride, there was obtained a colloidal calcium phosphate which could be precipitated by acid or by rennin. Olive oil was emulsified in this, and a stable imitation milk was obtained.

Several instances exist in the literature where this principle has been unwittingly used to produce ultra-fine dispersions. Thus in the *grainless* emulsion of Lippmann (so called because of the fact that it is transparent), the recipe calls for the addition of gelatin to each of the reacting solutions of potassium bromide and silver nitrate. Carey Lea produced some of his finest colloidal silver by adding the protective Rochelle salt to the silver nitrate and to the ferrous sulphate. Lobry de Bruyn (*Rec. trav. chim.*, **19**, 236, 1900) produced extremely fine precipitates or even colloidal solutions by adding gelatin to each of his reacting solutions.

The value of this principle in technology is obvious, and in medicine and in biochemistry it must be of exceedingly great importance, for in the organism all reacting solutions are protected. The work of Augusto Lumière and others has shown the disastrous consequences that follow the formation of floccules of sufficient size to cause nerve irritation, capillary embolism, and the wide variety of symptoms that may follow more or less directly or indirectly from the appearance in the blood stream of particles of unusual dimensions. In addition, protectors very generally lead to the formation of crypto-crystalline structures, obviating sharp crystalline deposits.

Autoprotection

Since every substance, in the course of aggregating from atomic or molecular dispersion into visible masses, must of necessity have in it at some time particles of colloidal dimensions, we must face the condition known as *iso-colloidism*, wherein the colloidal dispersion of the substance is in contact with a non-colloidal phase of the same substance. If the colloidal phase has the property of being adsorbed or of adsorbing, we may have *autoprotection*, where the substance delays or prevents its own crystallisation. The work of Quincke, O. Lehmann, and others indicates that crystal formation is preceded by the formation of tiny globulites; and by rapid evaporation of a film of a solution of sulphur in carbon disulphide containing a little Canada balsam to slow down the aggregation process, these globulites and their various stages of aggregation may be seen (J. Alexander, Colloid Symposium Monograph, Univ. of Wisconsin, 1923). An analogous adsorption seems to delay the transformation of γ-iron into α-iron (allocolloidism), and it is especially observable in ammonium salts and in soaps, *e.g.*, in oleates.

In the case of solutions, where the viscosity is not too great, the autoprotective stage is of limited life. Thus the gels formed by cooling solutions of 5-dimethylaminoanilino-3, 4-diphenylcyclo-1, 2-dione in organic solvents (W. B. Hardy, *Proc. Roy. Soc. Lond.*, 87A, 29, 1913); by dibenzoyl-1-cystine (Gortner and Hoffmann, *J. Am. Chem. Soc.*, **43**, 2199, 1921); by camphorylphenylthiosemicarbazide (Forster and Jackson, *J. Chem. Soc.*, **91**, 1881 (1909), dissolved in organic solvents—all become crystalline within a comparatively short time, which may run into weeks.

Cumulative Protection

Anything that changes the nature or degree of aggregation of a protector will influence the stability of the dispersion stabilised by it. This may be brought about by heat (albumin), coagulants (*e.g.*, ferric chloride, by flocculating gum arabic, "breaks" emulsions made with the gum), enzymes (rennin converts lactalbumin into a coagulant in addition to destroying its protective action in milk (J. Alex-

ander, 8th Inter. Cong. Appl. Chem., 1912). We may, therefore, have protectors for protectors, through a whole series.

This conception may lead us to understand some of the peculiar phenomena observed in mixtures. Thus the individual silicates in glass tend to crystallise, but in admixture they form a mutually protective chain, being so chosen by the glass technologist. If the mixture is not right, or if it has been allowed to remain too hot for too long a time, the chain breaks down, and the glass suffers devitrification. In alloys, especially in complex alloys, we may in this manner conceive how even small percentages of some of the constituents may exercise a potent influence.

In biological mixtures such as the gluten of wheat or rye flour the principle of cumulative protection is of consequence, and it may be that many of the proteins (albumin, gelatin, globulin, casein) may be adsorption complexes of simpler chemical compounds, which do not break up under the conditions to which they are ordinarily subjected. This view is consonant with the fact that, although some proteins are not definite chemical individuals, they are approximately uniform in composition.

RANCIDITY AND THE KREIS TEST

By T. W. JONES, B.Sc.

The rancidity induced in fats and oils by deterioration is important economically if for no other reason. Exactly what it is in the fat or oil that constitutes rancidity is still one of the numerous incognita of the chemistry of oils and fats; it is, therefore, a matter for some surprise that the literature upon the subject is not more extensive, for really very little attention appears to have been given to the problem. Several theories have been advanced to account for the phenomena, and a certain amount of work has been done upon the conditions giving rise to rancidity, with the result that, with reasonable care, the possibly heavy losses that would occur through deterioration of stored fats can be avoided. Exposure to light, heat and the atmosphere causes the rancidity of fats; moisture appears from recent work to be but a secondary factor, whilst bacteria thrive only when nitrogenous material is present, such as animal tissue and the marc of fruit remaining from crude methods of extraction.

It was at one time supposed that the acidity of oil was the same thing as its rancidity, but this was disposed of by experimental investigation, as was also the converse theory that rancidity could set in without the liberation of free fatty acids. It is now generally accepted that if an oil is rancid then it contains a fair proportion of fatty acids. Another theory that was quashed was that the aldehydic bodies always found in a rancid oil or fat were responsible for the rancidity; recent work, however, may have the effect of reviving this theory, as it appears that rancidity may be directly concerned with the presence of acrolein.

With this confusion regarding the nature of rancidity it is no wonder that a satisfactory test has not yet been evolved for its detection. Though rancidity can scarcely be ignored when well developed in any oil or fat, yet in its initial stages, especially if masked by a strong natural odour of the oil, its detection is sometimes a matter of difficulty, and on these occasions a positive chemical test is to be desired. It is not difficult to mix a slightly "off" oil with a fresh one that has a strong natural smell in such a way as to disguise its deterioration effectively for the comparatively short period it is on the market. It is to detect such adulterations that it is imperative to have a trustworthy test. Of those proposed the most successful so far and most generally used is the Kreis test, a modification of Bishop's test for sesamum oil. This test consists in shaking the suspected fat or oil with strong hydrochloric acid and then with an ethereal solution of phloroglucin. A rancid fat yields a red or pink colour. Kreis ascribes the reaction to the presence of aldehydes and ketones in the rancid fat, as a similar colour results when the test is applied to such compounds as vanillin, eugenol and so on.

This test has been widely used of recent years and consequently its value has been very thoroughly investigated. The result has been that a certain amount of doubt has arisen regarding its e[illegible]acy for the purpose of detecting rancidity. [illegible]l,[1] for example, objected to it on the grounds [illegible]) it is not specific and gives the same col[illegible] with aldehydes and ketones not found in [illegible]ils, (b) the colour is not proportional to the [illegible] cidity, and (c) lastly, the test is too d[illegible]cat[illegible] oils were to be condemned on the stren[illegible] reaction many that were perfectly fit [illegible] have to be discarded. A few years a[illegible] ton Meat Inspection Laboratory[2] m[illegible]0 to 20·0 study of the test which confirmed [illegible]5·0[illegible] and it was found, in addition, that certa[illegible] ticularly crude and freshly refined cotto[illegible] even when perfectly fresh and sweet, gave the co[illegible] reaction. The Laboratory did, however, find the test of value for confirmatory purposes and for samples where the natural odour masked that of rancidity; also it was concluded that its extreme sensitiveness was not wholly a drawback, as it was found to give evidence of an incipient rancidity which in every instance developed later. The test, therefore, is of use in giving warning of the onset of rancidity some time before the changes have progressed to such a point as to be evident to the senses. Similar conclusions were reached by J. F. Bevis[3]: "Under most conditions the interval of time between the first appearance of the Kreis test and the sensible appearance of rancidity is sufficient to permit the conservation of the product by immediate use."[3] The Kreis test as modified by Kerr[4] is carried out as follows:—

To 10 c.c. of the suspected oil or melted fat is added 10 c.c. of hydrochloric acid (sp. gr., 1·19) in a large test tube (8×1 in.). This is then stoppered and shaken vigorously for approximately 30 seconds. 10 c.c. of a 0·1 per cent. solution of phloroglucin in ether is then added, and the whole well shaken and

allowed to stand. A red or pink coloration in the acid layer indicates rancidity.

This test is given for comparison with the Powick test for acrolein and also because it shows the modi-ation used by Bevis[3] and Holm and Greenbank,[5,6] n their work. These workers tested the relationship etween the amount of oxygen absorbed by an oil or t and the intensity of the colour given by the re-lting oxygenated oil when the Kreis test was plied. This was done by bubbling pure oxygen ough the liquid dry fat at various temperatures at given rate and withdrawing samples at regular ervals for testing. All three found that there was proportionality between the rancidity and the th of colour produced by the test. According to m and Greenbank there is, however, a specific t proportion between the amount of oxygen orbed and the colour intensity; or "the amount fat necessary to give an equivalent colour with Kreis reagent is inversely proportional to the ount of oxygen absorbed, up to a certain limit." ey also found that in every experiment where an preciable oxidation had occurred the resulting fat ponded accordingly to the Kreis test, indepen-ntly of the degree of rancidity. These results point the invalidity of the Kreis test as a specific one for ncidity, a conclusion also reached by Bevis.

Whether any information can definitely be drawn om this work as to the nature of rancidity or not, ertain findings concerning the role played by oleic id are important, and it is possible that future quiry will ascribe the responsibility for this condi-n to the acid. Of the various fats and pure fatty ids examined by Holm and Greenbank, oleic acid as found to produce the greatest intensity of colour r an equivalent oxygen absorption, and further e induction period of autocatalytic oxidation was ortest with this acid. The induction period of re butter fat was also shorter than for lard, which ntains a far smaller percentage of oleic acid. In ddition, Bevis found that the presence of additional e oleic acid in a fat increases the rate of formation f the compounds causing the Kreis reaction.

Powick[7] in work on the rancidity of oils and fat as evolved a new test for acrolein, which is a modifi-ation of the Kreis test of Kerr:—

To 1 or 2 drops of diluted acrolein solution in a test-tube is added 1 drop of an approximately 3 per cent. solution of hydrogen peroxide. After about one minute, 5 c.c. of concentrated hydrochloric acid (sp. gr., 1·19) is added and the test-tube shaken. Finally 5 c.c. of an ethereal solution of phloroglucin is added and the whole shaken. A deep red colour is immediately imparted to the hydrochloric acid phase, which on spectroscopic examination shows a well-defined, fairly narrow absorption band in the yellow green region.

The modification thus consists in the use of hydrogen peroxide and the spectroscopic examination. In the absence of hydrogen peroxide the red colour is not obtained, and when an excess of acrolein is used the condensation product separates as a purple precipitate. Identical results are obtained with rancid fats, but *not* with such aldehydic substances as vanillin, eugenol, cinnamic aldehyde, and non-rancid cottonseed oil which also react with the Kreis reagent; with these the "spectra of the colours obtained show a general absorption throughout the green blue-violet part of the spectrum." Powick therefore concludes that the substance responsible for the Kreis test in rancid fats is the same as that formed by the action of hydrogen-peroxide on acrolein, and that this substance differs from the reactive substance in certain non-rancid cottonseed oils. Powick's results also point to the possibility that the free oleic acid in rancid fats is an active factor in the production of rancidity. It seems, however, from the results of Bevis and Holm and Greenbank that it is not the oleic acid molecule so much as its decomposition products that play the important part. One experiment given by Holm and Greenbank in another paper[8] is significant. Three small vessels containing equal amounts of fresh, dry butter fat are connected in series so that air may be blown through them. To the last vessel (No. 3) is connected an upright tube to act as a condenser. The three are then immersed in water at 100°C., and air is blown through them. It is found that No. 3 is the first to show signs of auto-oxidation, and No. 1 will resist oxidation the longest. This can be explained by the assumption that volatile oxidation products of Nos. 1 and 2 are carried over to No. 3, and catalytically hasten the oxidation of the fat there. It has long been known[9] that by blowing air through oleic acid volatile oxidised products are obtained; and the active substances carried to No. 3 are probably the decomposition products of the oleic acid in the butter fat, which has such a potent effect upon its reaction with the Kreis reagent.

That the oleic acid decomposition, or rather oxidation, product may possibly be identical with the acrolein-hydrogen peroxide complex is further indicated by the fact that acrolein-decomposition products, acrylic, acetic and formic acids are always found in fully rancid oils. The significance of the production of acrolein on heating all animal and vegetable fats needs no stressing. Further investigation of Powick's test will probably reveal this identity beyond doubt. Further investigation of the test is undoubtedly required before it can be finally accepted; but it appears to be the long-desired specific test for rancidity.

9 Dict. of Applied Chem., Thorpe.

The Société des Produits Azotés, at its recent meeting reported progress at its Bellegarde-Lannemezan and Martigny works, stating that the latter works, equipped for the production of calcium carbide with a supply of 50,000 to 60,000 k.w., was supplied with only 10,000 to 12,000 k.w., and it was decided to increase the supply of energy.

MINERAL OUTPUT IN THE UNITED STATES IN 1923

Figures showing the outputs that have been reported so far of various minerals in the United States in 1923 are as follows:—

	1923		22
Bismuth (metallic) ..	472,000 lb.	..	— lb.
Selenium	64,000 lb.	..	123,56[illegible]
Tellurium	1,000 lb.	..	—
Carbon black (produced from natural gas)	138,262,648 lb.	..	67,795,129 lb.
Clay	3,434,660 s.t.	..	2,647,700 s.t.
Fuel briquettes ..	696,810 n.t.	..	619,425 s.t.
Gypsum	4,753,448 s.t.	..	3,779,949 s.t.
Mica	9,086 s.t.	..	7,180 s.t.
Quicksilver	7,937 flasks		6,375 flasks.
Peat	61,355 s.t.	..	60,680 s.t.
Slate	726,800 s.t.	..	607,680 s.t.
Tin (metallic) ..	7,466 s.t.	..	9,108 s.t.

Nearly two-thirds of the 1923 output of bismuth was sold at $2·25 to $2·94 a pound, the smaller lots bringing the higher price. Ores containing appreciable amounts of bismuth were produced in 1923 from mines in Arizona, Idaho, Montana, Nevada, and Utah. The United States is believed to have been the largest producer of bismuth in 1923.

Only two companies reported the production of selenium in 1923, and most of the supply was in demand by the glass and ceramic industries, though a little was used in experiments. The output of tellurium and its compounds in the United States is very small, but the copper refineries ... annually between 100,000 and ... element should uses be found ... of clay products ... United States, and there

Clay available for the ... is widely distributed in every State in the Union. ... are clay-working ... 1923 increased by 30,703 short ... Imports of ... cent. in quantity, and $266,348, or 8 ... tons, or 9 ... value compared with 1922. The quantity ... per ... exported increased by 37,219 tons, or 78 per cent., and the value increased $195,295, or 45 per cent. compared with 1922.

Production in the fuel briquette industry has tended steadily upward during the last sixteen years with but four interruptions. The outstanding feature of 1923 was an increase of 48 per cent. in production at plants in the Eastern States. The combined output in Wisconsin and Pennsylvania constituted more than 67 per cent. of the total amount for the country. Of the 14 briquetting plants that were in operation in 1922, 13 were active in 1923, and the plant of the Virginia Fuel Corporation at Portsmouth, Va., commenced operations. The estimated world production of fuel briquettes in 1923 was approximately 37,500,000 m. t., a decrease of about 14 per cent. compared with the output in 1922.

In 1923 for the first time the quantity of gypsum mined in the United States exceeded 4,000,000 s. t., showing an increase of 26 per cent. over that of 1922.

From figures available from North and South America and Africa, the world's output of mica for 1923 appears to be only 10,929 m. t., but figures from other countries are not yet reported. Mica imported into the United States in 1923 amounted to 7,330,853 lb., and the total value of mica exported was $182,162, against $129,186 in 1922.

The condition of the mercury-mining industry in 1923 was somewhat better than in 1922. There was an increase of nearly 14 per cent. in the average price at San Francisco and an increase of nearly 25 per cent. in the production. If the new mercury boiler should prove as successful in practice as is believed by its sponsors, an increased demand for quicksilver will undoubtedly arise, but this demand is not likely to be great in the immediate future. Should it eventually become so a large part of the quicksilver to satisfy it will have to be sought in foreign countries. Italy continued to be the world's largest producer of quicksilver in 1922 and 1923, the output in 1922 being nearly 44 per cent. above that of 1921, though it had not yet reached the amount which the deposits now in Italian possession showed themselves capable of yielding before the war. In 1923 there was a smaller increase in production of mercury. The output of Spain in 1922 was more than double that of 1921 and was greater than that of any other year since 1911. In 1923, however, there was a distinct decrease ... amount ... purt ... number of producing mines in the United States ... from 10 in 1922 to 14 in 1923.

FORTHCOMING EVENTS

Dec. 19. SOCIETY OF CHEMICAL INDUSTRY, South Wales *Section*. Joint Meeting with the ... Institute of Chemistry, the Chamber of Commerce, Exchange Buildings, Swansea, at 6.30 p.m. "Fire Damp Explosions," by Prof. R. V. Wheeler, D.Sc.

Dec. 19. SOCIETY OF DYERS AND COLOURISTS, *Scottish Section*, "Gelatine Colours and their Application," by J. W. Wilson.

Dec. 19. SOCIETY OF DYERS AND COLOURISTS, *Midlands Section*, "Destruction of Wool by the Action of the Atmosphere," by S. R. Trotman and R. W. Sutton.

Alteration.—The January meeting of the Manchester Section of the Society of Chemical Industry which had been arranged for January 2 is now arranged for January 9. In this meeting it is hoped that in addition to the paper by Messrs. Simpkin and Sinnatt, the Section will have the honour of welcoming and hearing a paper by Prof. Hugh S. Taylor of Princeton University, U.S.A., the title of his address to be "The Properties of a Catalytic Surface."

USES OF COBALT

At a recent meeting of the Société des Ingénieurs Civils, M. L. Guillet read a paper on recent applications of cobalt. After describing the well-known utilisation of cobalt as a compound, the speaker pointed out the harmful effect of cobalt in brasses and aluminium bronzes, and said that cobalt did not offer much possibility of use for improving the properties of metals, but was of interest for the manufacture of permanent magnets, high-speed steels, and for electro-plating.

SOCIETY OF CHEMICAL INDUSTRY

SUSPENSION OF ENTRANCE FEE

As an inducement to Chemists to become members, the Council has resolved that no entrance fee shall be paid by members joining the Society in 1925.

A form of application for membership was inserted at the end of this Section in the issue of the Journal for October 17, and it is hoped that it may be used to introduce a new member for next year.

BACK NUMBERS OF JOURNAL

The General Secretary will be glad to hear from Members or Subscribers who have copies of the *Journal* for January 4, June 13 and 27, July 4 and 25, September 19, or October 3 and 17, 1924, that they are willing to dispose of to the Society.

LIBRARY OF THE CHEMICAL SOCIETY

The Library of the Chemical Society will be closed for the Christmas Holidays at 1 p.m. on Tuesday, December 23, and will re-open at 10 a.m. on Monday, December 29.

LIST OF MEMBERS ELECTED, December 12, 1924

Askew, H. O., "Fairlawn," 643, Fulham Road, London, S.W. 6
Bain, William, Ashbourne House, Whitechapel Road, Cleckheaton, Yorkshire. Analytical Chemist.
Balns, Leslie, 5, Carlton Road, Stroud Green, London, N. 4. Chemist.
Bührig, William H., The Fleischmann Laboratories, 158th Street and Mott Avenue, New York, N.Y., U.S.A. Chemist.
Burman, Henry, "Dunaverty," Provanmill, Millerston, Glasgow. Analytical Chemist.
Burns, A. C., 6, Oakbank Avenue, Chorlton-cum-Hardy, Manchester. Chemist.
Chevassieu, Henri, Société de la Soie Artificielle d'Izieux, Izieux, Loire, France. Director.
Cheshire, Arthur, 21, Cavendish Drive, Rock Ferry, Birkenhead. Chemist.
De Ganahl, Carl, Isle of Grain, Kent. Oil Refiner.
Donovan, W., Dominion Laboratory, Wellington, New Zealand. Assistant Dominion Analyst.
Frost, Granville B., Dept. of Chemistry, Queen's University, Kingston, Ontario, Canada. Lecturer.
Gibson, Reginald O., 41, Peak Hill, Sydenham, London, S.E. 26. Research Chemist (Industrial).
Godber, Joseph, 30, Frant Road, Tunbridge Wells, Kent. Director.
Hess, Eric H., c/o Adolph Hess & Bro., Ltd., Kirkstall Road, Leeds. Managing Director.
Hossack, James, 679, Echo Drive, Ottawa, Canada. Chemist.
Katsuyama, Katsujiro, c/o Mitsubishi Shogi Kaisha, Ltd., 117, Fenchurch Street, London, E.C. 3. Chemical Engineer.
Kearns, W. E., Cowpe Mills, Waterfoot, near Manchester. Cotton Yarn Dyer.
Lewis, Philip S., The Muspratt Laboratory, The University, Liverpool. Research Student.
Light, Alfred K., Dept. of Public Works, Ottawa, Ontario, Canada. Chemist.
Long, William L., 537, Brinton Street, Germantown, Philadelphia, Pa. U.S.A. Chemist.
Lunt, Clifford, 66, York Street, Runcorn, Cheshire. Chemist.
Marson, Cecil B., Fuel and Metallurgy Dept., The University, Leeds. Gas Research Fellow.
Martin, Frank A., 56, Windsor Terrace, Gosforth, Newcastle-on-Tyne. Works Chemist.
Mitchell, Helen G., The Horticultural College, Swanley, Kent. Lecturer.
Mitchell, Thomas C., Templehall Buildings, 168, Quarry Street, Hamilton, Scotland. Research Assistant.
Monk, Harold E., 27, Kenwyn Road, Wallasey, Cheshire. Assistant to City Analyst.
Moth, Leonard Alfred, 24, Holborn Viaduct, London, E.C. 1. Analytical Chemist.
Parrish, Eric, 157, Cheetham Hill Road, Manchester. Research Student.
Parrish, John, 155, Hertford Road, Waltham Cross, Herts. Technical Chemist.
Roberts, Thomas J., Ingleside, Huyton, near Liverpool. Lecturer.
Scruton, Harold A., 192, Victoria Avenue, Hull, Yorkshire. Research Chemist.
Simpson, Louis, 172, O'Connor Street, Ottawa, Ontario, Canada. Consulting Engineer.
Slater, Victor W., 139, Ashburnham Road, Luton, Beds. Industrial Chemist.
Smart, Thomas F. M., The Clayton Aniline Co., Ltd., 68½, Upper Thames Street, London, E.C. 4. Manager.
Southall, Colin L., Suva, Fiji Islands. Analytical Chemist.
Steed, Walter A., 72, St. John's Road, Isleworth, Middlesex. Analytical Chemist.
Stoton, Percy F., 20, Mill Street, Wincanton, Somerset. Chemist.
Streather, Alec T., 3, Wellington Road, Watford, Herts. Works Chemist.
Swint, Wendell R., c/o E. I. du Pont de Nemours and Co., 54, New Broad Street, London, E.C. 2. Chemical Engineer.
Sword, James, 14, Percy Street, North Kelvinside, Glasgow. Assistant to Professor of Chemistry.
Taylor, George, 17, Great Tower Street, London E.C. 3. Analytical Chemist.
Taylor, L. R., c/o The Lautaro Nitrate Co., Ltd., Oficina Santa Luisa, Taltal, Chile.
Thwaites, John A. C., 14, Holly Avenue, Whitley Bay. Chemist.
Thompson, Joseph, Altorf, Holywood Road, Belfast. Miller and Manufacturer.
Tunstall-Behrens, Brian, 36, Meadway, Golders Green, London, N.W. Analytical Chemist.
Voge, Cecil I. B., 4, Cluny Avenue, Edinburgh. Student.
Walton, Milton, c/o Messrs. I. Brown and Co., Ltd., Manufacturing Chemists, Savile Town, Dewsbury. Chemist.
Whitmore, Richard D., Food and Drug Laboratories, Health Dept., 317, Queen Street, Ottawa, Ontario, Canada. Chemist.

NOTTINGHAM SECTION

A joint meeting with the Society of Dyers and Colourists was held on November 27, Mr. S. H. Pentecost presiding. The Society recorded its sorrow at the loss of Mr. J. T. Wood and its sympathy with Mrs. Wood.

Mr. G. H. Ellis then read a paper on "The Dyeing of Acetate Silk." Mr. Ellis stated that artificial yarns produced by the earlier methods differed materially from those produced by the Dreyfus process (which is responsible for the present day Celanese); the difference shows itself chiefly in the degree of impermeability. Although in comparison with other textile fibres the present Celanese is relatively impermeable, it is much less so than the earlier fibres, and it has also low conductivity and different optical properties. It is claimed therefore that garments made from Celanese are

relatively cool in summer and warm in winter. The yarns are also extensively used for insulating purposes. The tensile strength of the yarns particularly when wet has been increased and this together with a considerable elasticity renders it possible to process with facility. Cellulose-acetate as represented by Celanese is a very stable fibre as is shown by long ageing tests.

The earliest cellulose-acetate fibres of a number of years ago would only take up basic colours substantively after drastic treatment to swell the fibre. In the early days of Celanese (which is the registered trade mark of British Celanese, Ltd.) unsuccessful attempts were made to use ordinary dyestuffs such as direct cotton colours. In England the method of saponification or hydrolysis was elaborated, whilst in Switzerland the dyeing was done with simple basic colours without mordants, using inorganic salts, *e.g.*, magnesium chloride, for heavier shades. The saponification method was difficult to control, as faults were not apparent until the material was dyed and were then beyond correction. A very large percentage of the saponification was completed in the first five minutes, which meant an extremely sensitive process, which, on account of its rapidity, resulted in irregularity. Unevenness became greatly accentuated, since any portion of the surface first attacked by alkali subsequently absorbed more and became further hydrolysed in preference to the remainder. Further, there was a substantial loss in weight and some effect on the lustre, resistance to abrasion and so on; hence the saponification method was unsuccessful.

The ultimate solution of the problem lay in the synthesis of colours especially for cellulose-acetate which theoretical deduction showed would have to be molecularly simple, generally basic in nature but certainly not strongly acidic or salt-forming. It appeared certain that such colours would be insoluble in water, and it became necessary therefore first to devise a method of "solubilising" such insoluble compounds. The possibility of achieving physical or colloidal dispersion of water insoluble colouring matters was conceived. Many colouring matters answering to the above conditions would be oil soluble and considerable promise seemed to lie in the use of sulphoricinoleic acid which has the properties of an oil, but has miscibility with water, and in the form of its alkali salts is a very powerful protective colloid in aqueous dispersion systems. Thus simple colours were dissolved in hot sulphoricinoleic acid and the solution diluted down to suitable dyebath strengths. The method was next extended to cover unsulphonated fatty acids, neutralisation being first necessary to produce salts miscible with water. Subsequently the methods were greatly elaborated and numerous new discoveries made; the principle throughout was to obtain a high degree of solution in pre-treatment and to prevent subsequent aggregation or coalescence in the aqueous dyebaths.

The result of much research has produced what are known as "S.R.A." colours. Dyed samples were shown in which the dye was used in the form of a paste embodying the colouring matter compounded with agents or media colloidal solubilisation and subseq ... of dyebath conditions. In the discussion Mr. Pentecost pointed out that the process involved was entirely novel in that it achieved the dyeing with insoluble dyes in a very fine degree of dispersion, instead of in true solution. It should be noted that there was a whole series of these dyes, covering the entire range of the spectrum. Mr. Pentecost said he had noticed that with some materials the cotton constituent had become coloured even when temperatures of only 160°—170° had been used and no carbonated alkali, and he wondered whether a trace of alkali in the softened water was responsible. Another speaker enquired if it was possible to prepare a material in marketable condition in which the Celanese fibre was dyed and the rest left white. Another speaker enquired whether "S.R.A." dyes could be used for calico printing. In reply, Mr. Ellis said that the points to be attended to were (*a*) the temperature must be strictly governed, (*b*) avoidance of saponification, (*c*) mechanical occlusion. He did not think that the amount of alkali present in softened water would cause irregularities. Prevention of mechanical occlusion required very careful scouring. A hard twist would resist much better than a soft one. Some causes of unsatisfactory results were those alluded to above and it must also be remembered that a number of the dyes were oil soluble and consequently all the fabric must be freed from oily matter. In calico printing nothing more was needed than direct printing on with a suitable material such as gum tragacanth or British gum. After printing, the usual drying was carried out and ageing preferably with dry steam. The material would then stand soaping much better than cotton printed with ordinary cotton colours, in fact, the results nearly approached those obtained by mordant colours.

The fifth meeting was held on December 3, Mr. Pentecost presiding. Prof. W. E. S. Turner, D.Sc., read a paper entitled :—"A Study of Recent Attempts to Produce High Resistance Glasses."

The stability of glass was indicated by the fact that specimens are in existence which were made more than 3000 years ago. Glass made up to the sixteenth—seventeenth century was mainly of the soda-lime-silicate type. In the seventeenth century

appeared a new glass in which oxides of lead and potassium were extensively used in place of lime and sodium oxide. This glass was still in use for the best table glass. Glass chemical apparatus up to 1850 was mainly of the soda-lime-silica type. Glass rich in sodium oxide was appreciably attacked by water and acids and was therefore unsuitable for accurate quantitative experiments. Stass found that a glass of the composition SiO_2 77 per cent., CaO 10·3 per cent., K_2O, 7·7 per cent, and Na_2O, 5·0 per cent., resisted chemical action, and in 1860—1870 glass of this type was made by the Bohemians.

Starting with sodium silicate ($Na_2O.3SiO_2$), the substitution of CaO for Na_2O increased the stability. Glass containing less than 2 per cent. CaO was rapidly attacked by water, and as the amount of lime increased beyond 3 per cent. the corrosion rapidly diminished. The substitution of Na_2O by other alkaline earths or aluminium oxide gave similar results. The substitution of magnesia for lime gave a slightly more durable glass, whilst for zirconia and titanium oxide the results were intermediate between those for lime and magnesia.

The material extracted from the glass by corrosion varied with the type of the glass, but the alkali constituents were always in excess in the solution. The stability of high resistance glass was in general indicated by the actual solubility of the several oxides which compose the glass. The order of solubility of the commoner oxides used was as follows: K_2O, Na_2O, B_2O_3—BaO, CaO, MgO, PbO, ZnO—Al_2O_3, SiO_2, hence the more SiO_2 which can be melted into a glass, the greater the durability to water and acids. Boron trioxide, although relatively fairly soluble, behaved as an exception to the above rule since, up to a limiting value of about 12 per cent. B_2O_3, it not only increased the durability but reduced the coefficient of thermal expansion and gave the glass valuable optical properties; above 12 per cent. B_2O_3 the durability diminishes. In 1893, high resistance borosilicate glass was made at Jena, and since that time the use of B_2O_3 associated with high silica content had been extensively developed.

The resistance of a glass increased with the silica content, but the fusion point was correspondingly raised, hence the limiting silica content was mainly determined by the ability to bring the materials to a state of fusion in operations on a commercial scale.

In the discussion, Mr. Pentecost asked whether it would be possible to make dye-baths of glass that would not be stained by the dye. Dr. Firth asked if a glass which was initially readily attacked by water or acids became more resistant after several treatments with water or acid, also why it was impossible to work glass which had been subjected to the action of steam for some time, also the cause of opalescence after heating of combustion glass, and transparent silica ware. Dr. Prideaux enquired whether the use of manganese dioxide by the Romans was intentional or routine, the value of zinc oxide as a constituent of glass and also whether dust hastened devitrification. In reply, Prof. Turner stated that glass could not be used as lining for metal baths, owing to the difference of thermal expansion of metal and glass. Glass improved appreciably after repeated treatment with water and acids, the amount of glass dissolved diminished, particularly in soda-lime and the commoner glasses. Glass may be regarded as a colloid, and rapidly adsorbed gases and water vapour; this was greatest in glasses of high alkali content in which adsorption was followed successively by absorption, hydration, hydrolysis of silicates with the production of silica possibly as gel, and the corresponding production of alkali. On heating glass containing absorbed gases or more particularly water vapour the gas or water vapour was rapidly expelled under fracture of the glass. With glass of high silica content high temperatures caused the excess silica to separate as fine crystals; at 1140° amorphous silica was slowly converted into tridymite. The use of manganese dioxide was known to the Romans not only as a colouring agent, but also as a decolorising agent. The use of zinc oxide increased the refractivity and durability and lowered the thermal expansion. Dust favoured devitrification in so far as the particles were centres for the condensation of moisture and hence the glass was acted on intensively at these points. Therefore optical glass and the like should be kept dust free.

BIRMINGHAM AND MIDLAND SECTION

Dr. Twiss presided at the second meeting on December 9. Mr. D. R. Nanji and Mr. W. S. Shaw (Department of Fermentation and Brewing, University of Birmingham) submitted a paper on "The Role of Silica in Plant Growth: its Assimilation and Physiological Relation to Phosphoric Acid."

During the eighty-five years which have elapsed since Liebig first brought forward his theory, our views on the artificial fertilisation of land have undergone considerable modification, more especially when viewed from the standpoint of the colloidal and the biological conditions existing in the soil. We have come to regard elements such as nitrogen, phosphorus, potassium, calcium, magnesium, sodium, sulphur and iron as requisite for perfect growth, and it is now held that certain elements such as boron, fluorine, iodine, silicon, aluminium, manganese and zinc, which had been known to exert a toxic effect towards plants when present in concentrations above a certain limit, had, in fact, when present in very minute amounts, not only a stimulating and beneficial effect, but might even be essential in some cases. It had been held that silica fulfilled ecological functions in that plants grown in the presence of silica are able to withstand parasites and moulds to a greater degree than plants grown without silica. Recent investigations have shown that silica is capable of increasing growth, and this beneficial effect is particularly marked in soils deficient in phosphorus. Silica fulfilled an important function in plant metabolism, and the realisation of this fact should prove of immense service to agriculturists in combating plant pests and diseases. The great significance of this problem to the cotton and similar industries which suffer heavy losses annually in their inability to cope with disease, can readily be realised. Such a study would also reveal the influence of silica in modifying the physical nature of the plant tissues. Before such investigation can yield fruitful results it will be necessary to dispose of

methods for examining and estimating the forms in which a given constituent may be present in the plant tissue. By this means alone can we gain an accurate impression of the equilibrium between the different combinations of the same element found generally in plant tissues. Much work still remains to be done by the agricultural chemist on the mineral physiology of plants, and being specially interested in the physiology of the element silicon and its relationship to phosphorus, studies have been commenced by the authors with such plant tissues as the straws of various types which are known to be highly siliceous.

A paper on 3 : 3 - Diethylpentane was presented by Prof. G. T. Morgan, Mr. Sydney Raymond Carter, and Mr. Albert Edward Duck. 3 : 3 - Diethylpentane or tetraethylmethane, $C(C_2H_5)_4$, a tertiary paraffin, is of especial interest as having the most symmetrical structure of all the theoretically possible nonanes. From the general inorganic viewpoint this hydrocarbon acquired additional significance, because it may also be regarded as the initial member required to complete the following periodic series :

$$C(C_2H_5)_4,\ Si(C_2H_5)_4,\ Ge(C_2H_5)_4,\ Sn(C_2H_5)_4,\ Pb(C_2H_5)_4.$$

This paraffin had now been synthesised from diethylketone by the application of the Grignard and Frankland reactions, as summarised in the following scheme :

$$(C_2H_5)_2CO \rightarrow (C_2H_5)_3C{\cdot}OH \rightarrow (C_2H_5)_3C{\cdot}I \rightarrow C(C_2H_5)_4.$$

The hydrocarbon is a colourless liquid with a characteristic camphoraceous odour, having a melting point $-41° \pm 1°$ and boiling point $139{\cdot}2°/760$ mm. In its chemical properties diethylpentane exhibits the inertness which characterises a paraffin hydrocarbon. It does not decolorise bromine water or alkaline permanganate, neither is it attacked by concentrated sulphuric or nitric acids. Its physical properties, including the vapour density, liquid density, molecular volume, surface tension and refractive index, have been determined. A comparison of these properties with those of other hydrocarbons demonstrates the monomolecular character of 3 : 3 - diethylpentane. Moreover, they accord with the compactness and perfect symmetry which would be associated with the structural formula of tetraethylmethane.

A joint dinner with the local section of the Institute of Chemistry was held at the Queen's Hotel, Birmingham, on December 13, and Prof. G. T. Morgan, the chairman of the local sections, presided.

The toast, "Chemistry and Industry" was proposed by Professor F. W. Burstall, Dean of the Faculty of Science in the University of Birmingham, who stated that in his professional life as an engineer he had been greatly impressed by the developments in the chemical world. The developments in the production of synthetic drugs and artificial silk had been particularly marked and the chemist might now well direct his attention to the application of science to the home, and to the production of foods that would be available for immediate use merely by heating and which would to a large extent prevent the colossal waste that now took place. The toast was acknowledged by Mr. W. J. U. Woolcock, C.B.E., president of the Society of Chemical Industry, who insisted that there was practically no industry which did not owe much of its development to the work of the chemist. There was much to be done in inculcating in the public mind the precise function of the chemist and the great part he was playing in the life of the country. In the direction of propaganda a valuable work had been done by the displays in the chemical section of British industry at Wembley. The cost involved of over £100,000 was worth it, because it answered the question—Germany or this country? Formerly, the mass of our people, when they heard the word "chemicals" were apt to think only of Germany. This was no longer the case. To-day, it was recognised that British chemicals and the British Chemical Industry had an established place. The Wembley exhibition had brought home to the Britisher not only the great industrial developments that had taken place within the domain of chemistry, but the patient, plodding, and very often unrewarded research work that was going on; this was an absolute guarantee for the continued progress of the British Chemical Industry.

Mr. J. T. Bell, President of the Birmingham Pharmaceutical Association proposed the toast, "The Institute of Chemistry," and remarked that the institute had always had a peculiarly close relationship to Birmingham from the time when Sir William Tilden was Chemistry Professor at Mason College, and President of the Institute from 1891 to 1894. He gave an interesting historical sketch of the foundation of the various chemical organisations and bore tribute to the invaluable work done by the Institute in maintaining the high professional status of its members. Prof. G. G. Henderson, President of the Institute, in his reply, urged that the primary function of the Institute was to promote the welfare of the profession. It had a direct and personal interest in all its members and was anxious to provide them with information and advice. The foundation of the Society of Chemical Industry had a great influence for good in raising the status of the chemist. The men who laid the foundations of that Society, determined that it should be built up of self-governing sections, each independent within limits, but all linked together by a central body, upon the Council of which each section was represented. Thus, chemists from all parts of the country came together with a common aim and purpose, and in this way obtained a better understanding of one another's position. But he felt that the principal influence in promoting the development of the profession of the chemist was the steady, unceasing work which had been carried on by the Institute of Chemistry for 50 years. Several generations of chemists, representing every branch of the profession, had devoted time, thought and labour, for the benefit of their successors; and he thought it was incumbent upon all chemists to become members of the Institute. Not until every chemist in the country was a member would they be able to speak, if necessary, with one voice upon matters of national importance. Chemistry and other scientific work must become of increasing importance to this country and, indeed, to every country; and if the mass of the people was to realise

the significance and importance of the work of the chemist, the aid of the press would have to be invoked.

The toast of "The Guests" was proposed by Prof. G. T. Morgan, who said that the unemployment list of the Institute would not have been confined to its present modest proportions but for the Safeguarding of Industries and the Dyestuffs Acts. Prof. J. G. Smith replied.

SOCIETY OF DYERS AND COLOURISTS

A meeting of the Manchester Section was held on December 12, Mr. J. Huebner, M.Sc., presiding.

A paper entitled, "Recent Experiments on the behaviour of Aluminium Hydroxide towards Dyestuffs and Salts," by J. K. Wood, D.Sc., and A. Wooller, M.Sc., was read by the first-named author.

Mr. Wood said that the behaviour of titanic acid and of stannic acid towards dyestuffs was influenced by the mode of preparation of the compounds in question. This influence of the mode of preparation was attributed to the amphoteric character of the substances, which made it possible for them to adsorb either acid or alkali from the solution in which they were being produced, so that, according to the condition of the solution, there was either acetate on one occasion or alkali on another, thus giving rise to products capable of taking up acid dyes or basic dyes, respectively. Similar results might be obtained with other amphoteric substances, and it might be said that a hydroxide like aluminium hydroxide could either have the adsorption of an alkali or the adsorption of an acid, according to the condition of the solution in which it was being made, and that would lead to a difference, according to the mode of preparation, in behaviour towards dyestuffs. The paper described experiments on the behaviour of what had been termed hydrated aluminium oxide or hydrated alumina, because the amount of water was variable and there was no very definite compound.

There was some difficulty in preparing hydrated alumina free from impurity, and the behaviour of the product towards dyestuffs was often influenced by the impurity present. Hydrated alumina had more affinity for acid than for basic dyes, and evidence was adduced to show that with basic dyes the fixation of the colour involved an exchange between the acidic impurity in the hydrated oxide and the acid of the dyestuff.

A second paper, "On Alkali Cellulose," by Prof. E. Knecht, Ph.D., M.Sc., and J. H. Platt, B.Sc., was read by Prof. Knecht, who said that it was now more than eighty years since Mercer, in 1844, when filtering a solution of caustic soda of 60° Tw. through a filter, composed of a six-fold layer of cambric, noticed that the filtrate had been reduced in strength to 53°. The experiment led to the discovery of the mercerising process. During further investigations of his "sodaised" cotton, Mercer was led to conclude that on treating cotton with caustic soda of roughly 45° Tw., a definite compound was formed, represented, according to the present way of writing it, as one of cellulose to one of caustic soda. Later, Dr. Gladstone showed that the amount of alkali taken up was one-half of that assumed by Mercer, and that definite compounds, represented by the formula of two of cellulose to one of caustic soda or potash, had been formed. Since then, and especially within the last twenty-five years, the question of the composition of alkali-cellulose occupied the attention of numerous investigators, some of whom had confirmed the views held by Mercer and by Gladstone, whereas others had maintained that the amount of alkali taken up by the cotton fibre was a variable quantity depending upon the constitution of the caustic alkali. "Alkali cellulose" was the product which resulted when cotton was subjected to the action of strong caustic soda or potash. Beyond 40° Tw. the compound formed by caustic soda possessed a constant composition which corresponded to that obtained in another way by Dr. Gladstone. The same was found to hold good for caustic potash beyond a strength of 70° Tw.

BIOCHEMICAL SOCIETY

A meeting was held on December 8, when six papers were read.

I "Magnesium in Human Serum," by E. Watchorn. A series of nine normal individuals gave values ranging from 2·23 to 2·50 mg. per cent., except in one case whose serum contained on one occasion only 2·09 mg. per cent. Thirty-two pathological cases were investigated, of which only six had a normal magnesium content of the serum, the remainder having increased values, ranging from 10 to 40 per cent. Magnesium chloride ingestion caused an increase of 21 per cent. During and immediately preceding menstruation the magnesium was found to be considerably decreased (sometimes by 40 per cent.) in four cases where the function was accompanied by marked physiological disturbance, but increased in one case investigated where there was no such disturbance.

II "The Oxidation of Amino Acids by Fungus Tyrosinase," by M. E. Robinson and R. A. McCance. A study has been made of the oxidative deamination of glycine, alanine and leucine by a tyrosinase from *Lactarius Vellereus*, in the presence of *p*-cresol, resorcinol and catechol. The oxygen uptake, the change in amino nitrogen and the liberation of ammonia have been estimated.

III "The Effect of Gelatin Feeding on the Thyroid Gland," by G. M. Findlay. When gelatin is fed to rats as the sole source of protein in an otherwise complete diet death invariably occurs in from two to four weeks. The only constant pathological finding is an atrophic condition of the thyroid gland, characterised by the disappearance of all colloid material and the collapse of the walls of the vesicles. The addition of cystine and tyrosine to the gelatin does not prevent this change in the thyroid.

The following papers were also communicated :—

"The Isolation of a Hydrolysis Product of the Proteins, hitherto undescribed," by H. W. Buston, H. N. Mukherjee, and S. B. Schryver. "Some Transformations of Casein," by H. Mastin and S. B. Schryver. "The Separation of the Proteins of Egg-white in an Electric Field," by Dorothy Griffiths and S. B. Schryver.

CORRESPONDENCE

WHAT IS THE THEORY OF INDUCED POLARITIES ?

Sir,—I recently took exception (this vol., p. 1109) to the following statement made during the course of a discussion on a paper of Prof. Pyman's: "The theory assumed that when oxygen and nitrogen are both present, the former is the negative key-atom." As Prof. Pyman had merely been applying, to his own observations, the "principle of induced alternate polarities" (which is not based on any theory, but is essentially a restatement in generalised terms of experimental observations) I naturally assumed that Dr. Flürscheim's remark was not a disingenuous attempt to confuse the principle with a variety of attempts which have since been made to explain its theoretical significance.

I preferred to assume that Dr. Flürscheim spoke in ignorance or forgetfulness, and although his reply to my protest suggests that his remark should be interpreted otherwise (this vol., p. 1160), I should be sorry to accept that suggestion.

In the circumstances, however, I, as one of several who have made tentative efforts to discover a sound theoretical basis for the "principle" in question, have good reason to wonder how Dr. Flürscheim justifies the application of the description: "the theory of alternate polarities" to certain views expressed conjointly by Robinson and Kermack rather than to others expressed by Sir Joseph Thomson, by Dr. Henstock, by Prof. Lowry or by myself.

This multiplicity of theories makes Dr. Flürscheim's offer all the more sporting, of course, unless he himself again assumes the responsibility of deciding which of the five or six brands of "theory" is to be tested and when its postulates fail. As to Dr. Flürscheim's own theory, I have expressed my own *opinion* of it in my last letter to you. I long ago signified my concurrence with some of his postulates, and my dissent from that based on Werner's carboxylic acid theory in the Annual Reports for 1909 (vi., pp. 58—61).—I am, Sir, etc.,

The University, Manchester A. Lapworth

THEORY OF SUBSTITUTION IN AROMATIC COMPOUNDS

Sir,—In your issue of November 21, p. 1161, Dr. Flürscheim replies to certain points raised by Prof. Lapworth by quoting some excerpts from publications in part by me, and in regard to which Prof. Lapworth cannot be assumed to have accepted any responsibility. For my own part, I am ready to defend all the postulates quoted by Dr. Flürscheim, but suggest that their application has been misunderstood. It is true that the tendency of the oxygen atom to acquire a negative charge and a stable octet is greater than that of the nitrogen atom, but whether this tendency can become effective or not will certainly depend on the circumstances of the case, and especially on the structure of the molecule and the mechanism of the particular reaction considered. To take the analogy of a game of chess, the queen is potentially the most powerful piece on the board and in simple cases will, with the best play, always overpower a weaker hostile piece, whilst in complex positions even a pawn may sometimes prove a more efficient instrument. Similarly, in complex molecules an oxygen atom may meritoriously succeed in stabilising its octet, and yet the process proves to be futile because it has no relation to the changes which can occur in the molecule under the particular conditions of experiment.

A sovereign has a higher purchasing power than a penny, but this cannot be proved by a test with an automatic machine. Again, in readily reversible reactions the final point of attachment of a group, where more than one possibility exists, will chiefly depend on the stability of the product. In such cases electro-valencies tend to be replaced by co-valencies, and the result anticipated from the elementary process of sign-labelling is reversed.

Absolute rules are rare in organic chemistry, yet in connexion with aromatic substitution there are several to which no exceptions exist. For example, it appears to be always true that the existence of free electrons (lone pairs) in the octet of an atom directly attached to the nucleus connotes strong *o-p*-directive effect. This is easy to understand on the electronic theory of conjugation, because the levelling out of valency, which is one of the prime factors affecting the direction of chemical change, can occur with the aid of free electrons with the minimum of disturbance. In this case the electronic theory is useful both for classification and explanation. What is the equivalent in other theories of valency? In order to avoid misunderstanding it should be stated that the above proposition cannot be reversed; *o-p*-orientation does not always depend on the existence of free electrons.

The whole subject cannot be adequately discussed in correspondence columns, but I do wish to assert that the criticism which has recently been directed against the applications of the electronic theory of valency to organic chemistry has not resulted in the production of a single definite case to which these theories are inapplicable. Prof. Ingold has made very interesting observations on the addition of nitrosobenzene to unsaturated compounds, and it is significant that, on his interpretation of what polarity theories predict, everything goes the wrong way. This indicates order at least, but as in every other case the meaning of the results cannot be discussed until the mechanism of the reactions is elucidated. It is impossible to accept without question the constitutions assigned to the substances formed in the additive processes when the only method of analysis is by thermal decomposition.

The University, Manchester R. Robinson

PERSONAL AND OTHER ITEMS

Mr. George Eastman, founder of the Eastman Kodak Co., who has already given away half his holding of stock in that company, has given the remaining half, roughly, $15,000,000, to various institutions of learning. About $8,500,000 will go to the University of Rochester, and $4,500,000 to the Massachusetts Institute of Technology, both institutions which have previously received large gifts from Mr. Eastman.

Sir John Cadman has returned to London from Persia, where he has been for over two months.

Mr. H. J. Turner, head of Messrs. Charles Turner and Sons, Ltd., colour, varnish and japan manufacturers, London, died recently, aged 93.

Mr. L. E. Hinkel has been awarded the D.Sc. degree of the London University, for a thesis entitled "Reactions in the Hydro-aromatic Series, resulting in the Formation of Aromatic Compounds."

The Royal Society

At tho 262nd anniversary meeting of the Royal Society, the president, Sir Charles Sherrington, announced that Prof. O. W. Richardson, noted for his work on thermionics, has been appointed to the third Research Professorship which has been provided from the munificent gift of Sir Alfred Yarrow. The Society's medals were awarded as follows: The Copley Medal to Sir E. Sharpey Schafer for his physiological researches; the Rumford medal to Prof. C. V. Boys for his services in producing apparatus for accurate physical measurements; a Royal medal to Sir D. Clerk for his work on the internal-combustion engine; a Royal medal to Dr. H. H. Dale for his researches on the action of ergot; the Davy Medal to Prof. A. G. Perkin for researches on the natural organic colouring matters; and the Darwin Medal to Prof. T. Hunt Morgan for his researches into the theory of organic evolution.

The following officers and members of council were elected: President, Sir Charles Sherrington; Treasurer, Sir David Prain; Secretaries, Mr. W. B. Hardy and Mr. J. H. Jeans; Foreign Secretary, Sir Richard Glazebrook; other members of council, Sir Frederick Andrewes, Prof. J. H. Ashworth, Dr. F. W. Aston, Sir William Bragg, Professor S. Chapman, Sir Dugald Clerk, Dr. H. H. Dale, Prof. F. G. Donnan, Prof. A. S. Eddington, Prof. E. S. Goodrich, Sir Thomas Holland, Prof. J. B. Leathes, Prof. T. R. Merton, Dr. G. C. Simpson, Prof. J. F. Thorpe, and Prof. F. E. Weiss.

Cast Iron Research Association

In the unavoidable absence of Lord Weir, Mr. H. B. Weeks presided at the Third Annual Meeting of the Cast Iron Research Association in London on November 19. The Chairman laid stress on the great progress made during the year, and summarised the main developments, particularly the extended research programme, and the establishment of a laboratory. The report and accounts were adopted, these showing a considerable improvement.

Sir John Dewrance, K.B.E., was elected President for the period 1924–26, and the following were elected Vice-Presidents:—Mr. G. Pate, O.B.E., J.P. (Falkirk), Mr. S. Hunter, C.B.E., M.Inst.C.E. (Wallsend-on-Tyne), Mr. F. W. Firth (Sheffield), Mr. C. E. Lloyd, O.B.E., M.P. (Dudley), and Mr. W. B. M. Jackson (Chesterfield). Commander C. W. Craven, O.B.E., R.N., and Prof. T. Turner were re-elected Vice-Presidents for a further year. A great tribute was paid to the services rendered to the Association by the retiring President, the Rt. Hon. Lord Weir of Eastwood, P.C., who was elected an Honorary Member, and retiring Vice-Presidents, Mr. M. Deacon, Vice-Admiral Sir George Goodwin, Mr. A. Laing, C.B.E., Mr. P. W. Petter, J.P., and Mr. Douglas Vickers.

Mr. A. J. Burn, Mr. F. J. Cook, Mr. T. Donaldson, Mr. N. B. Ellington, Mr. J. Haigh, Major C. Howl and Mr. M. Riddell were re-elected to the Council. Dr. W. Rosenhain, F.R.S., and Prof. T. Turner were elected Honorary Members, and Dr. Rosenhain suitably responded, expressing the hope that there would be even greater co-operation in future between the Association and the Ferrous Alloys Research Committee. Delegates nominated by tho leading technical institutions were elected, and thanks expressed to the professors and scientists who assist in the work of the Association.

The French Coal and Iron Industry

Production for the month amounted to 3,837,378 tons, an increase on the August output which was 3,691,153 t., the daily production being 147,591 t., compared with 144,680 t. in January, and 136,147 t. in January, 1913. Developments in the Nord and tho Pas de Calais increased the daily production from 60,239 t. in January, 1923, to 85,539 t. in September, 1924, daily. In the Central and Southern districts the amount of coal extracted during the month was 5569 t. daily. The total daily production of the mines situated along the old frontiers was only 5569 t. less than that in 1913. The production of metallurgical coke in France rose in September to 223,810 t. Of coal and lignite 2,083,499 t. was imported of which 1,026,808 t. came from Great Britain, and 227,896 t. were exported. Imports of coke amounted to 417,610 t., of which 368,274 t. came from Germany, and 45,108 t. were exported.

During the first nine months of 1924, 34,215 t. of cast-iron was imported, and 549,933 t. exported; 7534 t. of ferro-alloys was imported, and 14,436 t. exported. Exports of iron and steel amounted to 1,675,575 m. t., and imports to 537,861 m.t.; 38,613 m.t. slag was exported, and 56,888 m. t. imported.

Sugar Beet Subsidy

It is announced that the Government has decided to carry out the proposals made by the late Government for the grant of a subsidy for a period of ten years on a diminishing scale to sugar manufactured in this country from home-grown beet, coupled with a minimum price to the growers in the initial years.

The proposed subsidy, which will apply to sugar manufactured during the current season, will be at the rate of 19s. 6d. per cwt for the four years from 1924-25 to 1927-28 inclusive; at the rate of 13s. per cwt. for the three following years; and at the rato of 6s. 6d. per cwt. for the three final years. These rates will apply to sugar of a polarisation exceeding 98 deg.; for sugar of lower polarisations the rates will be reduced according to scale. The subsidy has been fixed at a rate which will enable the sugar factories to pay excise duty at the preferential rate, which at present is 9s. 8⅔d. per cwt., and the industry would not be adversely affected in future by any reduction in the Customs duty on imported

sugar, since the Excise duty would be proportionately reduced at the same time. It will be a condition of payment of the subsidy that the sugar manufacturers should pay during the first four years a minimum price of 44s. per ton of beet of 15½ per cent. sugar content, with an addition or deduction of 3d. per ton in respect of each one-tenth per cent. of sugar content above or below 15½ per cent.

The Government proposes also that in the case of any new sugar factories it shall be a condition of the payment of the subsidy that not less than 75 per cent. of the value of the machinery and plant shall be of British manufacture, unless the Minister of Agriculture for any special reason dispenses with this condition.

The necessary measures have been prepared and will be presented to Parliament when it meets for business. It will not be possible to complete the stages before Christmas, but it is the intention of the Government to secure their passage into law without any avoidable delay.

Adulteration of Food

Mr. J. F. Liverseege, F.I.C., city analyst of Birmingham, gave an address on "The Adulteration of Foods" before the members of the Biochemical Society of the University of Birmingham, on December 4, Prof. A. R. Ling presiding.

Mr. Liverseege said that 5000 samples of drugs and food were taken in Birmingham annually, or about 530 samples per 100,000 of the population, and about 5 per cent. was adulterated. From 1897 to 1901 9·3 per cent. of the milk samples contained boric acid or formic aldehyde; but to-day less than one in a thousand samples was adulterated in that way.

During the war, when bread was dear, a curious preparation which claimed to prevent bread losing moisture and to impart flavour and colour was put upon the market, but it was useless as it consisted of starch, Epsom salt and calcium phosphate. At one time boric acid was largely used as a preservative in sponge cakes, and it was used during the war period in imported liquid eggs for making sponge cakes. He had found Gorgonzola cheese adulterated on the outside by a paste of barium sulphate and tallow, sometimes coloured with oxide of iron, whilst rice had been adulterated with French chalk, used, it was said, to protect it against the weevil. Glucose had been used in making sweets, and then as the glucose picked up moisture, a coating was given of paraffin wax. There were instances many years ago of vinegar having been adulterated with sulphuric acid, and he had found samples containing boric acid and salicylic acid. One recent sample consisted of jam marked, "Prepared from refined sugar," but which contained glucose syrup. Adulteration was not common in Birmingham, and the large proportion of traders did their best to supply the public with the article they required and paid for.

Answering questions, Mr. Liverseege stated that dried milks now had to be labelled in accordance with their composition. Under the new labelling regulations the sale of dried skimmed milk as dried milk should be stopped. The word "adulteration" did not come in under the Food and Drugs Act, but such products, including medicine, should be in accordance with the nature, quality and substance demanded by the purchaser. Various products sold under proprietary names could not be defined by the public analyst. There was no standard, so that the public analyst was without power to support a prosecution, unless, of course, such proprietary article was injurious to health. A difficult question like that of the use of saccharin in jam ought to be dealt with not only by a local authority, but by the Ministry of Health. He had on one occasion found golden syrup adulterated by solid glucose.

Prof. Ling said if the manufacturer mixed his food products upon proper lines preservatives should be unnecessary. He condemned the use of glucose in golden syrup as an adulteration.

Power Alcohol from Beet

An influential deputation formed by the British Power Alcohol Association has, according to *The Times*, asked the Minister of Agriculture to extend the proposed subsidy of 19s. 6d. per cwt. on sugar produced from beet to the sugar content of beets used for making power alcohol. Some of the chief points mentioned were the agricultural importance of the beet crop and the serious need of an alternative motor fuel to petrol. The value of sugar beet as a cleaning crop in the rotation and its effect in increasing the following crop of cereals was emphasised, whilst the additional farm labour required and the value of by-products of beet as food for stock were also pointed out. It was urged that if these arguments were strong in the case of sugar they were stronger as regards power alcohol, because central factories were much cheaper to construct, used larger quantities of beet and worked continuously throughout the year. The need of producing power alcohol, in view of the growing consumption and the rapidly diminishing sources of it, had been impressed on the country by various Government Committees, and the deputation strongly urged that it was essential for economic and strategic reasons that we should not be dependent on foreign sources for our motor fuel supplies. If the subsidy were granted, the comparative cheapness of an alcohol factory would prove a guarantee against the creation of monopolies, as it was the aim of the British Power Alcohol Association to encourage the establishment of central factories on a co-operative basis, the farmer supplying the beet to have participation in the profits, and a first claim on a portion of the product. Large sums were lost annually because our main supplies of liquid fuel were drawn from the United States, in consequence of the adverse exchange conditions. Foreign countries, including the United States, where were the largest supplies of petrol, were entertaining large schemes for the development of power alcohol. The main object of a subsidy being to place an infant industry in a position to stand on its own feet, it was important to know whether at the end of the proposed subsidy, namely 10 years, power alcohol could be made in this country to compete with petrol. Leading experts who have examined this question on behalf of the Association were satisfied that at a cost for beet which

could make the sugar industry just pay its way if present prices for sugar were maintained, power alcohol could compete easily with petrol, even if the average post-war petrol price were not to be exceeded, a supposition which seemed unlikely. For the safety of the country against economic or military attack, it was essential that the power alcohol industry should be established here, and the amount of the subsidy would probably be more than compensated for by reduction of the dole and saving in exchange on purchases of American motor spirit.

Whilst addressing the Rotary Club at Wolverhampton, Mr. Alfred Wood said that the British Sugar Beet Society, which represented all interests in this new industry, undertook to make every effort to comply with the condition of the subsidy, which was to secure such economies arising from education, experience and efficient organisation as to enable it to become self-supporting in the period of ten years covered by the Beet Subsidy Bill. Four of the six promised factories at Ely, Kidderminster, Spalding and Ipswich were expected to be ready for the 1925 crop of beet, and the farmers, through the National Farmers' Union, were co-operating with the manufacturers in every possible way. Prof. A. R. Ling, of Birmingham University, Mr. T. H. P. Heriot, of the Royal Technical College, Glasgow, and Dr. A. Wijnberg, formerly principal for twenty-five years of the school for the sugar industry of Holland, were engaged upon the consideration of a scheme put forward by the Society, in which universities and beet sugar factories would be invited to co-operate,

Mineral output of Canada in 1923 and 1924

According to revised statistics received from the Dominion Bureau of Statistics, the Canadian mineral output in 1923 was as follows :—

	Quantity	Value $
Asbestos	231,482 tons	7,522,506
Copper	86,881,537 lb.	12,529,186
Lead	111,234,466 lb.	7,985,522
Nickel	62,453,843 lb.	18,332,077
Salt	206,985 tons	1,713,516
Silver	18,601,744 f. oz.	12,067,509
Zinc	60,416,240 lb.	3,991,701

Finally, revised figures for gold production in 1923 show 1,243,341 fine ounces, valued at $25,702,139.

The total value of metallic production during the first six months of 1924 amounted to $47,496,000 as compared with $39,581,000 during the same period in 1923. The value of gold produced was $14,475,000, an increase of $3,511,000 and the silver production amounted to $5,881,000, an increase of $74,000. The value of nickel showed an increase of $1,789,000, whilst that of lead was $6,278,000, an increase of $2,700,000.

Physics and Chemistry of Paints and Varnish

The study of the fundamental principles at the basis of any manufacture has always proved valuable in helping progress in the industry. Organised consideration of the scientific basis of paint and varnish technology has not been conspicuous, however, in this country, though, in the United States, the U.S. Paint Manufacturers' Association has established an energetic and prolific research department. It is, therefore, of interest to call attention to the course of lectures on the above subject (which also includes synthetic resins), which are to be given at the Battersea Polytechnic by Mr. A. A. Drummond, M.Sc. The Principal of the Polytechnic, Dr. R. H. Pickard, D.Sc., F.R.S., states that the lectures are designed to indicate the lines along which scientific development is being made and the many openings for further investigation. Such a course is well worth attention by young technologists engaged in the industry and should provide a valuable stimulus to progress.

The Action of Light on the Photographic Plate

Dr. T. Slater Price, O.B.E., F.R.S., addressed the Chemistry Section of the Leicester Literary and Philosophical Society, on December 3, at the Museum, Leicester. He gave a brief account of the main principles of the "Action of Light upon the Photographic Plate," illustrated by experiments and lantern slides, and then proceeded to describe the recent work of his own Research Association and of others. Mr. Hubert Pooley, M.Inst.C.E., presided. A short discussion followed.

Research in Cotton

On December 3 the foundation stone of the Technological Research Laboratory at Bombay was laid, and the Viceroy also opened the spinning-plant of the Indian Central Cotton Committee. This function marks an important development in the Indian cotton industry and it is difficult to over-estimate the value of the new laboratory to India. Properly controlled spinning tests will be undertaken for the Agricultural Departments, and the laboratory will also arrange for full-scale mill-trials before new cottons are brought into general cultivation The Research Laboratory thus formed will be the only one in the world concentrating on the improvement of raw material and the investigation of the growers' needs.

Knecht Testimonial Fund

In view of the great service rendered by Prof. E. Knecht, Ph.D., M.Sc., to the Society of Dyers and Colourists over the long period of forty-two years, for forty of which he was Foreign Editor of that Society's Journal, it has been decided that a testimonial should be presented to him. Those desirous of taking part should send their donations to the "Knecht Testimonal Fund," addressed to the Secretary of the Society of Dyers and Colourists, 30, Pearl Assurance Buildings, Bradford.

"Rayon" the New Name for Artificial Silk

The Council of the Silk Association of Great Britain and Ireland has approved the adoption of the word "Rayon" in place of the name, "Artificial Silk." The object is to eliminate the word "silk," and ensure the use of "Rayon" as a descriptive term for all classes of artificial silk, so that "Rayon Silk" would be incorrect. The word "Rayon" has already been largely adopted in the United States by representative organisations in the trade.

REVIEWS

The Extra Pharmacopœia. Vol. I. By W. Harrison Martindale, Ph.D., F.C.S., and W. Wynn Westcott, M.B., D.P.H. 18th Edition. Pp. xxxviii+1163. London: H. K. Lewis and Co., Ltd, 1924. Price 27s. 6d. net.

For the most recent information on drugs and medicinal preparations the pharmacist and the medical man have for many years found "The Extra Pharmacopœia" a safe and reliable book of reference, and the latest edition fully maintains its reputation. It is four years since the previous edition was published, and during that time much important work has been done in medical science. New methods of treatment are described under such headings as Colloidal Metals, Endocrinology, Insulin, Accessory Food Factors, Vaccines, etc. The information supplied is concise, thoroughly up-to-date, and includes a very large number of recent medical references which form one of the features of the book.

To the analyst concerned in the examination of foods and drugs, and to the consulting chemist when confronted with problems connected with pharmaceutical chemistry, this volume is especially valuable. It contains a vast amount of practical information based on the authors' own experiences and research, not only on processes of manufacture of medicinal substances, but also on clinical tests—the excellent summary of the Poisons Regulations and the intricacies of the Dangerous Drugs Acts constitutes an authoritative guide to the pharmacist. Every preparation which falls within the Poison Schedule or is classified as a "dangerous drug" is marked with a special sign throughout the book.

A few of the important new features deserve special comment. The authors have conducted a series of experiments on the preparation of tinctures and spirits of official drugs using isopropyl alcohol in place of ethylic alcohol, and have come to the conclusion that isopropyl alcohol is equally suitable for the extraction of such drugs as belladonna, benzoin, calumba, capsicum, cinchona, henbane and nux vomica. Although isopropyl alcohol is more toxic than ethylic alcohol, its use for medicinal tinctures, the dose for which is comparatively small and usually well diluted, is well worth consideration. For hair lotions, skin lotions and toilet preparations for which methylated spirit is unsuitable, isopropyl alcohol has been proved to be eminently satisfactory.

Activated alkaloids, in which the addition of an alkali is found to produce enhanced physiological effects, form the subject of a new chapter. Alkaloidal periodides have also received experimental treatment, both chemically and physiologically, at the hands of the authors, and their results are published exclusively in this addition. Arsenobenzol, the British equivalent of salvarsan, and the newest methods of administration are fully described, and many recent medical references are given.

Cocain and synthetic substitutes for local anæsthesia are fully dealt with, and details of their application are included. Under colloidal metals, the newest additions are described, with recent reports on the use of colloidal gold in neurasthenia, alcoholism and the morphia habit.

Emetine and its compounds, now largely employed in amœbic dysentery, have been given due prominence. In the chapter on nutriments, the accumulated knowledge derived from many original contributions on accessory food factors has been carefully abstracted and condensed. The effects of aeration, oxidation, pasteurisation and excessive heat on food products are clearly shown.

The subject of insulin, which has been prominently before the public during the last few years, is dealt with in about eight pages, its manufacture, distribution in nature, technique of injection, chemical examination, effects of excessive dose, etc., being fully discussed.

Under Endocrinology, new methods of treatment with animal substances, notably pituitary, thyroid, parathyroid and suprarenal glands are commented on, accompanied by notes on the manufacture and standardisation of their active principles and their physiological effects.

The section on vaccines and antitoxins occupies some seventy-five pages, illustrating the growing importance of this realm of medical treatment, notably in asthma, bronchitis, cholera, diphtheria, d[illegible] tuberculosis, typhoid and small-pox.

The enormous variety of drugs and pre[illegible] referred to in this minature pocket volum[illegible] to impress upon the reader the immens[illegible] ties of the present-day pharmacist. [illegible] tindale" is of incalculable value as a [illegible] and a veritable mine of information [illegible] the preface remind the physician "t[illegible] take exception to a chemist commun[illegible] on matters of doubt relating to presc[illegible] like. Therapy to-day is so extremel[illegible] complex that it is only by careful co-ope[illegible]on and mutual good will that mistakes can be c[illegible]ed and dire consequences be prevented." They plead also to the practitioner to help forward British industry, and ask medical men to assist the English chemical worker to their utmost. The compilers are to be congratulated on the production of a work well abreast of the times and meriting the highest praise.

C. T. Bennett

A System of Physical Chemistry. By W. C. McC. Lewis. Vol. III. The Quantum Theory. Pp. x+407. London: Longmans, Green and Co., 1924. Third edition. Price 15s.

During the last few years many books have been published on the quantum theory. This does not, however, make the third edition of Prof. Lewis's work less acceptable. The book contains a large amount of matter and gives quite clearly and definitely the principles of the application of the quantum theory to many phenomena.

The theory is introduced through a discussion of the problem of radiation in thermodynamic equilibrium. It is shown that classical statistical mechanics leads to a result not in agreement with experiment. Planck's conception of energy-quanta is then given, and the correct law deduced.

An account is given of the application of quantum principles to various problems, such as the energy

content of solids and of gases, thermionics, contact potential, the photoelectric effects, photochemical reaction and Nernst's heat-theorem. A long chapter (Chapter V) deals with the various theories of the structure of the atom, especially the theories of Bohr and Langmuir, which are given in some detail. The application of the Quantum Theory to matter in bulk is discussed in Chapter VIII, which deals with the theory of the ionic lattice and the molecular lattice. The volume has eight appendices, by various writers. These consist in general of a formal development of points in the theory which could not conveniently be treated in the text.

Whilst being mainly theoretical, the book contains an account of the principles of the fundamental experimental work, such as that of Nernst on the specific heat of solids, and the classical determination of Planck's constant by Millikan.

Altogether the book may be considered as a very useful addition to the literature on the subject. The theory is not yet by any means complete; quantum principles have been successfully applied, either partially or wholly, to a large number of problems, but progress is slow in the absence of precise ideas as to the true significance of the discontinuities involved. Each partial application meets with striking successes, and difficulties no less striking, and each reveals a separate aspect of the central problem, which itself remains unsolved. It is this difficulty which the author has had to encounter; he has tried to give as ordered an account as possible of the theory in its present incomplete state, and he may be congratulated on having achieved so much.

There are a few misprints in the book, but these are of a trivial nature, and the book is otherwise well printed and appears to be free from any serious errors. Diagrams are inserted wherever necessary, and these are invariably clearly drawn and of sufficient size.

The writer has no hesitation in saying that the work should prove of great value to all serious students of chemistry and physics. As a volume of a system of physical chemistry, it is written from a chemical point of view, but this should not make it less valuable to physicists. G. ERIC BELL

PHYSICAL AND PHYSICO-CHEMICAL PROBLEMS RELATING TO TEXTILE FIBRES. Reprinted from the Transactions of the Faraday Society. No. 59, vol. 20. Part II, 1924. Price 7s. 6d.

This is an account of a general discussion held by the Faraday Society and the Textile Institute at Wembley in June. The first impression one gets in perusing this volume is that the textile industry is now receiving the full searchlight of science. Previously it was mentioned that all branches of the industry were founded on what is generally called "rule of thumb" or "empiricism," and that these methods held sway until quite recent times. But this statement is difficult to maintain, for a century ago some quite distinguished scientists were engaged in the industry, and at all times textiles seem to have attracted as many men versed in scientific methods as other industries have. It is true that the results of scientific investigations in the industry have not always found publication, for the simple reason that nothing was to be gained by the broadcasting of information of industrial importance. But now we are living in another age, and many old business men are wondering what is to be the outcome of the spreading of this information. Certainly an enormous amount of work is being done, and those engaged in industry find it difficult to assimilate all the information and apply it to industrial use.

The introductory address at the Conference was given by Dr. W. L. Balls, in which he surveyed the field of research. He regards physics as the pivotal subject for industrial research in the textile industries during the next half-century. Most of the faults in cotton yarns to-day were faults intrinsic in the physical properties of the raw materials. When an industry was changing its technique, as the electrical industry always was, and the textile industry was now beginning to do, the scientist's place was very different from what it was in a stable industry, and the main reason why a scientist could be useful to an unstable industry was that the practical man took a very long time to get the answer in experimental work. Dr. Alexander Scott showed some slides of linen used in the shroud of Tut-ankh-Amen, and Dr. S. A. Shorter read a paper on the physical properties of textile fibres in relation to technical processes, emphasising the importance of the absorption of moisture by fibres and their elastic properties. He discussed some observations in the light of the theory of the colloid structure of fibres. Dr. T. Barratt gave measurements of the transparency of a fabric and of the lustre produced during mercerisation. The transparency of a fabric may be increased 30 per cent. by mercerisation, and the amount of light reflected from a mercerised cloth is less than from the unmercerised. A careful examination of a well-mercerised fabric will show a distribution of very bright and very dull points, the amount of reflected light being usually rather less than from the more uniformly lighted surface of an unmercerised fabric. This latter fact is due to the greater transparency of the mercerised fabric and the consequent loss of reflected light.

Some structural characters of the flax fibre were discussed by C. R. Nodder and properties of the silk fibre by Dr. W. S. Denham. Other papers are "The Fibre Balance," by Dr. T. Barratt; "The Action of Light on Textiles," by Dr. G. Barr; "Aircraft Fabrics," by Dr. J. E. Ramsbottom; "Recent Advances in the Experimental Study of Warp Dyeing," by F. D. Farrow; "A review of work on the Absorption and Desorption of moisture by Textile Materials," by A. K. Urquhart and A. M. Williams; and "The Function of Water in the Web Spinning of Flax," by Dr. W. H. Gibson. In some cases the papers were résumés of work previously published and abstracted in this Journal. A full account of the discussions which took place on the papers is given. The Faraday Society is performing very useful work in publishing such reports of its discussions.

COMPANY NEWS

CASSEL CYANIDE CO., LTD.

Colonel Sir Edward A. Brotherton, chairman of Brotherton and Co., Ltd., who has been elected chairman of the Cassel Cyanide Co., Ltd., in place of the late Sir George Beilby, presided over the ordinary general meeting, held in Glasgow, on December 10. The chairman referred to the death of Sir George Beilby, whose connexion with the company extended over thirty-two years, during which he rendered incalculable service to the company and to the cyanide industry, as well as to science and education generally. In moving approval of the annual report (*cf. Chem and Ind.*, Dec. 5, p. 1216), the chairman said that the demand for cyanide during the year was fairly satisfactory, and sales were well maintained in spite of active competition. Selling prices, however, suffered a further reduction, and they could look for no stability in this direction until a lower level was reached, although their product was already selling at less than pre-war prices. The company had been working during the past year on new processes of manufacture with a view to lowering production costs. Patents had now been issued and published, and covered quite a revolutionary process for the manufacture of metallic sodium, which was the base for the production of high-grade sodium cyanide. Their chief chemist, Dr. Ewan, was the inventor. The report was adopted.

POWER-GAS CORPORATION, LTD.

The twenty-fourth ordinary general meeting was held on December 10, Mr. E. Lloyd Pease (chairman) presiding. Although adverse conditions of trade still continued, important orders from all parts of the world had been received for the Corporation's specialities for the production of gas for heating and power, water gas and town gas, and the number of orders booked during the past financial year were considerably in excess of those of previous years. All the plants had given great satisfaction, and it was expected that a growing market would be found for these specialities. The Corporation owned all the shares in Ashmore Benson Pease and Co., Ltd., established about fifty years ago, at Stockton-on-Tees, for the manufacture of gasworks plant and general engineering work, but during the past year had derived no profits from this company, as, although it had secured a larger volume of orders, the prices obtained were unprofitable. After allocating £2000 to the reserve fund from the total profit of £23,267 (which included £11,070 brought forward), there was a balance of £21,267, which it was proposed to carry forward. It was considered that the interests of the company would not be served by making a distribution of profits this year, although it would be the first time for fourteen years that no dividend had been paid.

GENERAL PETROLEUM COMPANY OF TRINIDAD

In order to provide further working capital, the directors have decided to recommend the reconstruction of the company. They propose to form a new company with a capital of £400,000 in 2,000,000 shares of 4s., which will take over the whole of the assets of the present company in consideration for the payment of the liabilities of the present company and the allotment of 1,682,045 shares credited 2s. paid. Each "A" shareholder will be entitled to one share for every "A" share held, and each "B" shareholder one share for every two held, the new shares to be payable 6d. per share on application and the balance by instalments of 6d. per share, payable in March, May and July. The issue of the 1,682,045 shares will provide £168,204, and the subscription has been guaranteed in consideration of an underwriting commission of 7½ per cent. and an overriding commission of 2½ per cent.

BRITISH BURMAH PETROLEUM CO.

The report for the year ended July 31 showed a balance from revenue account of £195,079 (£224,253 last year), and a total credit of £219,273 including interest, dividends, etc. (£250,282 last year). After deducting expenditure, interest on debenture stocks and depreciation, there is a net surplus of £52,098 (£73,530). After adding £2916 balance brought in, £5810 surplus on realisations of investments, and £16,760 refund in respect of taxes, a total credit of £77,585 is shown (£152,849). The directors state that the reduction in profits is mainly due to the continued fall in the prices received for benzine, and do not consider that the profit earned is sufficient for the payment of a dividend. A more satisfactory result is anticipated this year, owing to higher extraction of products at the refinery, combined with further substantial reductions in working costs.

BRUNNER, MOND AND CO., LTD.

The shareholders of this company have been invited by the directors to subscribe to an unadvertised issue of 175,000 7½ per cent. cumulative preference shares at par in the Madeley Collieries, formed to acquire for £350,000 a certain colliery and brick works situated near Madeley, Staffordshire. Half the ordinary shares of the Madeley Co. are held by Brunner Mond and Co. The purchase price is to be paid half in cash and half in ordinary shares.

BRITISH PLATINUM AND GOLD CORPORATION

The accounts for the year ended July 31, 1924, show a net profit of £49,985, compared with £33,385 for the previous year, the amount to be carried forward being £51,583, as against £18,198. The directors have recommended a final dividend of 6d. per share, less tax, making 1s. 6d. per share for the year.

RUTHS STEAM ACCUMULATOR CO., LTD.

The controlling interest in the Ruths Steam Accumulator Co., Ltd., has been acquired by the Fairfield Shipbuilding and Engineering Co., Ltd., and James Howden and Co., Ltd., of Glasgow. The company was formed in April last for the purpose of marketing in the British Empire the steam accumulator invented by Dr. J. Ruths of Stockholm. A great deal of interest has been shown by technical firms in this country in the application of the accumulator in industrial plants, as it has been found that very large economies, together with increased production, are secured when the plant is installed in technical works.

By the terms of the licence all plants will be made in this country, and it is anticipated that considerable output will be secured. Three directors of each of the above companies will be on the board of the company, and Sir Alexander Kennedy, chairman of the Fairfield Shipbuilding and Engineering Co., Ltd., will be chairman.

BOOTS PURE DRUG CO.

An interim dividend has been declared on the ordinary shares for the quarter ending December 31, 1924, at the rate of 9 per cent., less tax.

UNITED INDIGO AND CHEMICAL CO.

An interim dividend has been declared at the rate of 5 per cent. per annum on the ordinary shares, less tax, payable December 31.

REPORT

Report of Test by the Director of Fuel Research on Parker Low-Temperature Carbonisation Plant installed at Barugh, Barnsley, at the Works of Low-Temperature Carbonisation, Ltd. Department of Scientific and Industrial Research. Pp. iv+24. H.M. Stationery Office, 1924. Price 9d.

This report describes a test carried out from July 22 24, 1924. The installation consisted of two settings of 32 retorts each, each setting being designed to carbonise 50 tons of coal per 24 hours. After briefly describing the plant and its operation, the report deals with the arrangements for and the conditions of the test. The coal used was Dalton Main, a medium caking coal, in the form of washed breeze up to half-inch pieces. The coal was clean, and of uniform quality. A weight balance was found to show a loss of 0·48 per cent., and this, in conjunction with the thermal balance loss of 5·2 per cent., is considered satisfactory. A complete examination of the products of carbonisation was carried out at the Research Station, details of which are included in the Report. The yields of products per ton of coal were as follows: Coke, 13·92 cwt.; gas, 5620 cb. ft. or 39·6 therms.; tar, 18·62 galls.; liquor, 26·00 galls.; crude spirit, 1·78 galls.; and ammonium sulphate, 13·55 lb.

The coke or smokeless fuel was of good quality, and the yields of tar, gas, and ammonia were high; the ammonia liquor was dilute (under 6 oz. strength), and the advisability of recovery is questioned. Spirit obtained by scrubbing the coal gas amounted to 1·78 galls. per ton of coal.

Details are also given of the working operations, of the labour and power required and of a variety of points in the handling of the setting. The temperature of carbonisation was not uniform throughout the setting, varying from 600° C. to as high as 800° C. Suggestions are given for the improvement of temperature control, as the 83·5 therms consumed per hour could be reduced considerably.

In an appendix the conditions are set out under which official tests are made of plants for the low-temperature carbonisation of coal.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech. ..	£21 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder..	£47 per ton.
Acid Hydrochloric ..	3s. 6d.–6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali.. ..	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder ..	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime ..	£7 10s. per ton, packages extra.
Borax, Commercial—	
Crystal..	£25 per ton.
Powder..	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride (Solid)..	£5 12s. 6d. to £5 17s. 6d. per ton, carriage paid.
Copper Sulphate	£25 per ton.
Methylated Spirit 64 o.p.—	
Industrial	2s. 7d.—2s. 11d. per gallon, according to quantity.
Mineralised	3s. 8d.—4s. per gallon, according to quantity.
Nickel Sulphate	} £38 per ton d/d. Normal business.
Nickel Ammon. Sulphate	}
Potash Caustic	£30—£33 per ton.
Potass. Bichromate ..	5¾d. per lb.
Potass. Chlorate.. ..	3d.—4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake..	£3 10s. per ton d/d.
Soda Caustic, solid ..	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5–£5 5s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate (refined)	£10 10s. per ton, carr. paid.
Sod. Bichromate.. ..	4¼d. per lb.
Sod. Bisulphite Powder 60/62%..	£17–£18 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. solid 60/65	About £15 per ton d/d.
Sod. Sulphide cryst. ..	£9 5s. per ton d/d.
Sod Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	6½d.—1s. 2d. per lb., according to quality.

Antimony sulphide—	
Crimson	1s. 4d.—1s. 6d. per lb., according to quality.
Arsenic, Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide	£30—£33 per ton, according to quantity.
Carbon Black	7d.—7½d. per lb. ex wharf.
Carbon Tetrachloride	£60—£65 per ton, according to quantity, drums extra.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes White and Dark	5d.—9½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	£48 per ton, barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£16 5s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Precip. B.P.	£50—£65 per ton, according to quantity.
Sulphur Chloride	4d. per lb., carboys extra.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep	5s. 1d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£11 5s. per ton, and upwards.
Grey	£14 10s.—£15 per ton. Firmer.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Demand brisker in many localities.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 9d. per gall. Unrefined.
Wood Naphtha—	
Miscible	4s. 9d. per gall. 60% O.P.
Solvent	5s.—5s. 3d. per gall. 40% O.P. Firmer.
Wood Tar	£4 10s.—£5 10s. per ton. Demand slack and stocks being held.
Brown Sugar of Lead	£42 per ton. Steady market.

TAR PRODUCTS

Acid Carbolic—	
Crystals	5¾d. per lb. Quiet.
Crude 60's	1s. 7d.—1s. 9d. per gall. Market quiet.
Acid Cresylic, 97/99	1s. 11d.—2s. 1d. per gall. Fair business.
Pale 95%	1s. 8d.—1s. 11d. per gall. Not much business.
Dark	1s. 7d.—1s. 9d. per gall. Market dull.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	6½d.—7½d. per gall. Small demand
Unstrained	6d.—6½d. per gall.
Benzole—	Prices advanced; supplies very scarce.
Crude 65's	9d.—11½d. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 9½d.—1s. 11d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5½d.—1s. 7d. per gall. More inquiry.
Toluole—Pure	1s. 7½d.—1s. 9d. per gall. Steady demand.
Xylol—Coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	8d.—8½d. per gall. Not much business.
Middle Oil / Heavy Oil / Standard Specification	5¼d.—6½d. per gall., according to quality and district. Market firmer. Steady demand.
Naphtha—	
Solvent 90/160	1s. 3d.—1s. 6d. per gall. Demand good. Market very firm.
Solvent 90/190	1s.—1s. 1d. per gall. Few inquiries.
Naphthalene Crude—	Cheaper in Yorkshire than Lancashire. Demand rather better.
Drained Creosote Salts	£3—£5 per ton. Steady but quiet.
Whizzed or hot pressed	£6—£9 per ton. No business.
Naphthalene—	
Crystals and Flaked	£12—£15 per ton, according to district.
Pitch, medium soft	50s.—60s. per ton, according to district. Plenty of inquiry for prompt and forward. Market very steady.
Pyridine—90/160	18s. 6d.—19s. per gall. Few inquiries.
Heavy	11s. 6d.—12s. per gall. Rather flat.

INTERMEDIATES AND DYES

Business in dyestuffs has been maintained but without further improvement.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 7d. per lb. naked.
Acid H.	3s. 10d. per lb. 100% basis d/d.
Acid Naphthionic	2s. 2d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid, Salicylic, tech.	1s. 0½d.—1s. 1d. per lb.
Acid Sulphanilic	9d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	10d. per lb. d/d.
Aniline Oil	8d. per lb. naked at works.
Aniline Salts	8½d. per lb., naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	3s. 10d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 1d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
p-Chlorphenol	4s. 3d. per lb. d/d.
o-Cresol 29/31° C.	3½d.—4d. per lb. Fair demand.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	2s. 3d. per lb.
Dichloraniline S. Acid	2s. 3d. per lb. 100% basis.
p-Dichlorbenzol	£85 per ton.
Diethylaniline	4s. 3d. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 2½d. per lb. d/d. Drums extra.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol	£84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine	2s. 10d. per lb. d/d.
G. Salt.	2s. 3d. per lb. 100% basis d/d.
Monochlorbenzol	£63 per ton.
α-Naphthol	2s. 4d. per lb. d/d.
β-Naphthol	1s. per lb. d/d.
α- Naphthylamine	1s. 3½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.

m-Nitraniline	4s. 2½d. per lb. d/d.
p-Nitraniline	2s. 2½d. per lb. d/d.
Nitrobenzene	5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. 3d. per lb d/d.
Nitronaphthalene	10d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s.. per lb. d/d.
p-Phenylene Diamine	10s. per lb. 100% basis d/d.
R. Salt	2s. 4d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 2d. per lb. 100% basis d/d.
o-Toluidine	10d. per lb. naked at works.
p-Toluidine	2s. 10d. per lb. naked at works.
m-Toluylene Diamine	4s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	£45 per ton, ex wharf London, in glass containers.
Acid, Acetyl Salicylic	3s. 1d.—3s. 3d. per lb., according to quantity. Sales steady. Price firm.
Acid, Benzoic B.P.	2s. 6d. per lb.
Acid Boric B.P.	Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 4½d. per lb. Increased demand.
Acid, Gallic	2s. 9d. per lb. for pure crystal in cwt. lots. Easier.
Acid, Pyrogallic, Cryst.	7s. per lb. Resublimed quality 8s. per lb. Market firm.
Acid Salicylic	1s. 6d.—1s. 8d. per lb., according to quantity.
Acid, Tannic B.P.	2s. 10d. per lb. Quiet steady demand.
Acid, Tartaric	1s. 1d. per lb., less 5%.
Amidol	9s. per lb. d/d.
Acetanilide	1s. 10d.—2s. per lb. More enquiry.
Amidopyrin	14s. 6d. per lb.
Ammon. Benzoate	3s. 3d.—3s. 9d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	13s. 9d. per lb. Slightly lower. Quiet steady demand.
Benzonaphthol	5s. 3d. per lb. spot.
Bismuth Carbonate	8s. 6d.—10s. 6d. per lb.
„ Citrate	8s. 6d.—10s. 6d. „
„ Salicylate	8s. 0d.—10s. 0d. „
„ Subnitrate	7s. 7d.—9s. 7d. „ According to quantity. Prices recently reduced.
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	Market less firm. Prices uncertain.
Ammonium	2s. 1d. per lb.
Potassium	1s. 10d. per lb.
Sodium	1s. 11d. per lb.
Calcium Lactate	1s. 6d.—1s. 8d. per lb., according to quantity. Fair demand and steady market.
Chloral Hydrate	4s. per lb.
Chloroform	2s. 6d. per lb. for cwt. lots.
Formaldehyde	£48—£49 per ton in barrels, ex wharf London. Supplies exceed demand.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free	7s. per lb.
Iron	8s. 9d. per lb.
Glycerophosphates—	
Magnesium	9s. per lb.
Potassium, 50%	3s. 6d. per lb.
Sodium, 50%	2s. 6d. „
Guaiacol Carbonate	9s. per lb. Reduced in price.
Hexamine	3s. per lb. for bold crystal. Powder slightly less.
Homatropine Hydrobromide	25s.—30s. per oz.
Hydrastine hydrochlor	English make offered, 120s. per oz.
Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. „
Iron. Ammon. Citrate B.P.	1s. 11d.—2s. 3d. per lb. Price recently reduced.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Light, pure	£46 per ton.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£25 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	57s. per lb. for December delivery.
Synthetic	26s.—35s. per lb., according to quantity. English make. Increasing demand.
Mercurials	Market very quiet. Mercury slightly firmer.
Red oxide	5s. 2d.—5s. 4d. per lb.
Corrosive sublimate	3s. 5d.—3s. 7d. „
White precip.	4s. 6d.—4s. 8d. „
Calomel	3s. 10d.—4s. „
Methyl Salicylate	1s. 9d.—2s. per lb.
Methyl Sulphonal	22s. per lb. Slightly weaker.
Metol	11s. per lb. British make.
Paraformaldehyde	2s. 8d. per lb. for B.P. quality.
Paraldehyde	1s. 2d.—1s. 6d. per lb. in free bottles and cases.
Phenacetin	5s. 6d. per lb.
Phenazone	6s. per lb.
Phenolphthalein	5s. 3d. per lb. for cwt. lots. Again lower in absence of active buying.
Potass. Bitartrate— 99/100% (Cream of Tartar)	86s. per cwt., less 2½% for ton lots.
Potass. Citrate	1s. 10d.—2s. 2d. per lb.
Potass. Ferricyanide	1s. 9d. per lb. Quiet.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Steady market.
Potass. Metabisulphite	7½d. per lb., 1-cwt. kegs included. F.o.r. London.
Potass. Permanganate	7½d. per lb. spot. Forward prices higher.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. per lb. in fair quantities. Supplies exceed demand.
Saccharin	63s. per lb., in 50-lb. lots.
Salol	3s. per lb. for cwt. lots. Slightly lower. Limited demand.
Silver Proteinate	9s. per lb. for satisfactory product, light in colour.
Sod. Benzoate, B.P.	2s. 6d. per lb. Supplies of good quality now available.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite— Photographic	£13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.

Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash. according to quantity.	
Sod. Nitroprusside ..	16s. per lb.	
Sod. Potass. Tartrate (Rochelle Salt) ..	75s.—82s. 6d. per cwt., according to quantity.	Quiet market.
Sod. Salicylate	Powder 2s. 1d.—2s. 3d. per lb. Crystal at 2s. 2d.—2s. 4d. per lb. Flake 2s. 6d. per lb.	Strong demand. Market firm.
Sod. Sulphide—		
Pure recryst.	10d.—1s. 2d. per lb.	
Sod. Sulphite, anhydrous	£27 10s. per ton, minimum 5-ton lots, increasing according to quantity, 1-cwt. kegs included.	
Sulphonal..	14s. 6d. per lb.	Little demand.
Thymol	18s. per lb.	

PERFUMERY CHEMICALS

Acetophenone	11s.	per lb.	Cheaper.
Aubepine	12s. 6d.	per lb.	Cheaper.
Amyl Acetate	3s.	,,	
Amyl Butyrate	6s. 6d.	,,	
Amyl Salicylate	3s. 3d.	,,	
Anethol (M.P. 21/22° C.)	4s. 6d.	,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 9d.	,,	
Benzyl Alcohol free from Chlorine	2s. 9d.	,,	
Benzaldehyde free from Chlorine	3s. 3d.	,,	
Benzyl Benzoate.. ..	3s. 6d.	,,	
Cinnamic Aldehyde— Natural..	18s. 6d.	,,	
Coumarin	17s. 3d.	,,	Again cheaper.
Citonellol	20s.	,,	
Citral	9s.	,,	Dearer.
Ethyl Cinnamate ..	12s. 6d.	,,	
Ethyl Phthalate	3s.	,,	
Eugenol	10s. 6d.	,,	
Geraniol (Palmarosa) ..	33s. 6d.	,,	
Geraniol	12s. 6d.—20s.	per lb.	
Heliotropine	6s. 9d.	per lb.	
Iso Eugenol	16s.	,,	
Linalol ex Bois de Rose..	26s.	,,	
Linalyl Acetate	26s.	,,	
Methyl Anthranilate ..	10s.	,,	
Methyl Benzoate.. ..	5s.	,,	
Musk Ambrette	50s.	,,	
Musk Xylol	14s.	,,	
Nerolin	4s. 6d.	,,	
Phenyl Ethyl Acetate ..	15s. 6d.	,,	
Phenyl Ethyl Alcohol ..	15s.	,,	Cheaper.
Rhodinol	50s.	,,	
Safrol	1s. 10d.	,,	
Terpineol	2s. 4d.	,,	
Vanillin	25s.—25s. 6d.	per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.	
Anise Oil	2s. 10d. per lb.	
Bergamot Oil	15s. per lb.	Cheaper.
Bourbon Geranium Oil ..	30s. per lb.	
Camphor Oil	65s. per cwt.	
Cananga Oil Java ..	11s. 3d. per lb.	
Cassia Oil, 80/85% ..	9s. 3d. per lb.	Cheaper.
Cinnamon Oil, Leaf ..	6½d. per oz.	
Citronella Oil—		
Java 85/90%	7s. per lb.	
Ceylon	3s. 4d. per lb.	
Clove Oil	8s. 3d. per lb.	
Eucalyptus Oil 70/75% ..	2s. 2d. per lb.	
Lavender Oil—		
French 38/40% Esters	38s. per lb.	
Lemon Oil	3s. 4d. per lb.	Dearer.
Lemongrass Oil	5s. 9d. per lb.	
Orange Oil, Sweet ..	11s. per lb.	
Otto of Rose Oil—		
Bulgarian	42s. 6d. per oz.	
Anatolian	28s. per oz.	
Palma Rosa Oil	17s. per lb.	
Peppermint Oil—		
Wayne County ..	45s. per lb.	
Japanese	23s. 6d. per lb.	
Petitgrain Oil	9s. 9d. per lb.	
Sandal Wood Oil—		
Mysore	26s. 7d. per lb	
Australian	18s. 6d. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before February 10th, 1925: they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on December 24th.

I.—Applications

Fothergill. Evaporators. 28,792. Dec. 1.

General Electric Co., Ltd., and Goldsmith. Filters. 29,348. Dec. 6.

Imray (Victoria Falls and Transvaal Power Co. and Andrews). Removal of calcium sulphate scale from condenser tubes etc. 28,801. Dec. 1.

McIntyre. Crushing or mixing machines. 28,701. Dec. 1.

Pennell. Filtering-apparatus. 28,800. Dec. 1.

Spangenberg. Separating particles from fluid streams. 28,810. Dec. 1.

Waring. Pulverising or grinding machines. 28,946. Dec. 3.

I.—Complete Specifications Accepted

13,891 (1923). Sauer. Treatment of liquids. (198,373.)

21,496 (1923). Fothergill. Evaporators. (225,271.)

30,282 (1923). Blantyre Engineering Co., Ltd., and Rogerson. *See* II.

31,767 (1923). McEntire. Centrifugal separator. (225,396.)

6394 (1924). Deutsche Ton- und Steinzeugwerke Akt.-Ges. Fine-grinding mills. (212,922.)

II.—Applications

Artificial Coal Co. (Hamon Process), Ltd., and Hamon. Manufacture of decolorising carbon from peat. 28,873. Dec. 2.

Beaudequin. Manufacture of combustible briquettes. 28,908. Dec. 2. (Belgium, 3.12.24.)

Bregeat. Manufacture of highly active carbon etc. 29,294. Dec. 6.

Crozier. Purifying oils. 29,013. Dec. 3.

Thoumyre Fils. Manufacture of combustible agglomerates. 29,100. Dec. 4. (France, 12.3.24.)

Wollaston. Gas-retorts. 28,717. Dec. 1.

II.—Complete Specifications Accepted

23,345 (1923). Bergh. Retort furnaces for treating bituminous materials. (204,067.)

25,854 (1923). Duplan. Furnaces for distillation and carbonisation. (225,337.)

29,940 (1923). Toogood, and Dempster and Sons, Ltd. Heating of horizontal retorts for gas production. (225,377.)

30,282 (1923). Blantyre Engineering Co., Ltd., and Rogerson. Plant for dehydrating coal, sludge, pulp, and the like. (225,379.)

2267 (1924). Brikettharz-Ges. Manufacture of combustible briquettes. (210,458.)

III.—Application

Murphy. 28 974. *See* IX.

III.—Complete Specification Accepted

29,312 (1923). Weil, and Chem. Fabr. in Billwarder. Manufacturing pure carbazol. (225,369.)

IV.—Applications

Farbenfabriken vorm. F. Bayer und Co. Manufacture of monoazo dyes. 29,133. Dec. 4. (Ger., 5.12.23.)

Soc. of Chemical Industry in Basle. Manufacture of dyestuffs. 28,905. Dec. 2. (Switz., 28.12.23.)

V.—Applications

Cross, and Viscose Development Co. Manufacture of cellulose products. 29,328. Dec. 6.

Ingham. Waterproofing paper. 29,079. Dec. 4.

Levy. Apparatus for manufacture of artificial filaments. 29,135. Dec. 4.

Plinatus. Gelatinisation of nitrocellulose etc. 29,110. Dec. 4.

Plinatus. Manufacture of films etc. 29,113. Dec. 4.

Plinatus. Process for dissolving and gelatinising nitrocellulose etc. 29,113, 29,232. Dec. 4 and 5.

V.—Complete Specifications Accepted

19,028 (1923). Lilienfeld. Treatment of textile products containing cotton. (216,477.)

4678 (1924). Jackson (Tubize Artificial Silk Co. of America). Manufacture of artificial silk. (211,889.)

VI.—Application

Testrup and Thomson. Bleaching etc. 29,331. Dec. 6.

VI.—Complete Specification Accepted

15,278 (1924). Schlumpf. Dyeing and washing textile material. (218,296.)

VII.—Applications

Carpmael (Farbenfabriken vorm F. Bayer und Co.). Manufacture of sulphuric acid. 29,247. Dec. 5.

Du Faur. Recovery of hydrated oxides of iron and calcium sulphate from sulphate solutions etc. 28,993. Dec. 3. (Australia, 21.1.24.)

General Chemical Co. Manufacture of contact sulphuric acid. 28,887. Dec. 2. (U.S., 21.12.23.)

Haglund. Treatment of raw materials containing highly refractory oxide. 29,035. Dec. 3. (Austria, 17.4.24.)

Phillips. Production of diamonds from amorphous carbon. 28,830. Dec. 2.

Plauson (née Hildenbrandt). Manufacture of nitrogen compounds. 28,734, 28,735, 28,736. Dec. 1.

Soc L'Air Liquide. Extraction of krypton and xenon from the air. 28,759. Dec. 1. (Fr., 19.1.24.)

VII.—Complete Specifications Accepted

21,008 (1923). Redfern (Pintsch Akt.-Ges.). Process for obtaining nitric oxide. (225,263.)

29,774 (1923). Pipereaut and Helbronner. Manufacture of titanic and zinc compounds. (207,555.)

31,634 (1923). Kidd. Production of soda crystals. (225,393.)

874 (1924). Deutsche Celluloid Fabrik. Recovering nitric acid from weak nitric acid liquors. (217,546.)

13,925 (1924). Soc. Anon. D'Eclairage et D'Applications Electriques. Extracting krypton and xenon from the atmosphere. (218,266.)

VIII.—Application

Deutsch-Luxemburgische Bergwerks- und Hütten Akt.-Ges. Manufacture of magnesite blocks. 29,234. Dec. 5. (Ger., 16.1.24.)

X.—Applications

Bureau d'Organisation Economique and Soc. des Ciments Français. Manufacture of fused cement. 29,048. Dec. 4. (Fr., 4.12.23.)

Murphy. Soluble tar etc. compound for roads etc. 28,974. Dec. 3.

Plinatus. Cement or adhesive compositions. 29,111. Dec. 4.

Plinatus. Packing and insulating materials. 29,112. Dec. 4.

Rigby. Manufacture of cement. 28,934, 29,148. Dec. 3 and 5.

X.—Applications

Allen. Treating metal surfaces. 29,070. Dec. 4.

Barrott Co. Treating non-ferrous metals. 29,312. Dec. 6. (U.S., 7.12.23.)

Cachemaille (Westinghouse Lamp Co.). Manufacture of refractory metals. 28,785. Dec. 1.

Curtius und Co. Treatment of cupriferous pyrites. 29,011. Dec. 3. (Ger., 10.3.24.)

Haglund. 29,035. *See* VII.

Speck. Annealing etc. furnaces. 29,057. Dec. 4.

Talbot. Metallurgical furnaces. 29,215, 29,216. Dec. 5.

Western Electric Co., Ltd. (Western Electric Co., Inc.). Metallic materials. 29,031, 29,032. Dec. 3.

X.—Complete Specifications Accepted

21,927 (1923). Constant and Bruzac. Reduction of metal oxides. (225,295.)

2205 (1924). Sankey and Sons, Ltd., and Martin. Pickling stainless iron and steel. (225,416.)

18,185 (1924). Lawson. Soldering-metal. (225,484.)

XI—Applications

Automatic Telephone Manufacturing Co., Ltd., and Hudd. Electrolytic cells. 29,106. Dec. 4.

Lewis. Electric accumulators. 28,850. Dec. 2.

Oldham, and Oldham and Son, Ltd. Accumulator plates etc. 28,784. Dec. 1.

Plinatus. 29,112. *See* IX.

Vignon. Dry cells etc. 29,016. Dec. 3.

XI.—Complete Specifications Accepted

25,716 (1923). Oldham and Son, Ltd., and Wilde. Galvanic batteries. (225,334.)

463 (1924). Weissman. Bipolar agglomerate for electric cells. (225,407.)

10,456 (1924). Soc. D'Etudes et de Constructions Metallurgiques. Electric arc furnaces. (225,458.)

XII.—Applications

Crozier. 29,013. *See* II.

Fulton and Hutton. Manufacture of detergents. 29,301, 29,302. Dec. 6.

Spearing. Soaps. 29,146. Dec. 5.

XIII.—Application

British Cyanides Co., Ltd., and Rossiter. Manufacture of artificial resins. 29,246. Dec. 5.

XIV.—Applications

Clarke. Rubber preservative. 28,740. Dec. 1.

Smith. Vulcanisation of rubber. 29,219. Dec. 5. (Italy, 6.12.23.)

XV.—Complete Specification Accepted

11,064 (1924). Schmid and Luttig. Treatment of hides and skins. (225,460.)

XVII.—Complete Specification Accepted

8901 (1924). Burmat. Treatment of bagasse. (225,449.)

XVIII.—Complete Specification Accepted

14,050 (1923). Jensen (Fleischmann Co.). Manufacture of yeast. (225,252.)

XIX.—Applications

Crosfield and Sons, Ltd , Hilditch, and Wheaton. Purifying or softening water etc. 28,773. Dec. 1.

Hartley. Purification of sewage. 28,696. Dec. 1.

Hartley. Purification of sewage. 28,842. Dec. 2.

XIX.—Complete Specifications Accepted

19,829 (1923). British Dyestuffs Corp., Ltd., and Lefebure. Insecticides and the like. (225,262.)

25,321 (1923). Hart. Purification of semolina middlings and other milling products of wheat. (225,331.)

XX.—Applications

British Cyanides Co., Ltd., and Rossiter. Preparation of thiocarbamide. 29,245. Dec. 5.

Farbwerke vorm Meister, Lucius, und Bruning. Manufacture of complex gold compounds. 29,329. Dec. 6. (Ger., 7.12.23.)

Ikeda. Manufacture of glutamic acid and salts thereof. 28,990. Dec. 3.

Rheinische Kampfer Fabrik Ges. Production of inactive menthol. 28,811. Dec. 1. (Ger., 4.4.24.)

XXII.—Applications

Plinatus. 29,110. *See* V.
Plinatus. 29,232. *See* V.

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number:—*Austria*: Hardware, tinplate (604); *China, Japan and Siam*: Chemicals, oils, photographic materials (626); *Egypt*: Palm oil soap (Inspecting Engineer, Egyptian Government, Queen Anne's Chambers, London, S.W. 1) (Muh., 1924/74/6); *Mexico*: Paints (B.X./1378); *Netherland East Indies*: Oils, soap, perfumery, paint, varnish, glass, enamelware (628); *New Zealand*: Steel (599); *Norway*: Galvanised corrugated sheets (616); *Sweden*: Copper, tin, lead, zinc (619); *Switzerland*: Oils (622); *Turkey*: Paint (625).

Output and Consumption of Coal in India, 1923

The total production of coal in 1923 amounted to 19,658,000 tons, which is 647,000 t. or 3·4 per cent. more than in 1922, but about 3,000,000 t. less than the record output in 1919. To this may be added some 393,000 t. estimated to have been taken out from mines by miners for their own use, making the total production in 1923, 20,051,000 t. There was an increase in the output of coal in all the provinces except the Central Provinces, Assam, Baluchistan, the Punjab and Rajputana, and for the first time the Talcher coalfield in Bihar and Orissa during the year under review turned out 4800 t., of good steam coal. Of the coal supplies of India, 98 per cent. are obtained from the Gondwana coalfields and 2 per cent. from Tertiary beds. The total estimated value of the output in 1923 was Rs. 14,61 lakhs. Owing to the fact that the coal in India which is now being worked is comparatively near the surface, and labour comparatively cheaper, Indian coal has a lower value at the pit's mouth than that of any other country except South Africa. In 1923, 200,918 persons were employed in the mining industry in India, a figure practically the same as in the preceding year. Imports of coal during the year fell to 625,000 t., compared with 1,221,000 t. the previous year, and the exports, 88 per cent. of which went to Ceylon and 11 per cent. to the Strait Settlements, amounted to 136,600 t. as against 77,100 t., in 1922, and 275,600 t. in 1921. The estimated consumption of Indian and foreign coal in 1923 was 20,100,000 t.

British Petrol

A new refinery for the production of B.P. motor spirit has been established at Grangemouth by Scottish Oils, Ltd. For the last five years the Scottish industry has supplemented its supplies of crude shale oil by refining crude petroleum imported from Persia, and this operation is at present being carried on very successfully in one of the shale-oil refineries set free for the purpose, and also in the large new refinery at Grangemouth.

Foreign Company News

The manufacture of phosphazote by the Société des produits chimiques de l'Artois has begun, and the Société des produits Azotés has formed, with this company and the Société Malétra, an association for the study of nitrogen and its derivatives. Next spring, the Artois and Malétra companies will absorb 15,000 metric tons of cyanamide, and will produce roughly double the quantity of phosphazote.

The group formed by the Viscose and the Kuhlmann Companies is studying the manufacture of artificial wool, the object being to treat cotton so as to give it some of the qualities of wool. When the process has been perfected, the group will probably form a company to work it.

Notes on Plant and Products

Messrs. Vickers and International Combustion Engineering have received the following orders:—A complete boiler-house equipment, to include two water-tube boilers fired with pulverised fuel, this being the first section of a plant which will eventually be six times the size; pulverised fuel plant for St. Pancras for firing two boilers of the Vickers Spearing type with Lopulco equipment; and pulverised coal equipment for the new cement-manufacturing plant at Holborough, in Kent.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council of Pure and Applied Chemistry

which consists of Representatives from

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals and the Royal Agricultural Society.

VOL. 43 NEW SERIES LONDON, DECEMBER 26, 1924 NO. 52

EDITORIAL

THE year is nearly at an end; the year is dying, let him die. He may have been good and kind to us, but we expect his successor to be better and kinder. Has it not been said that time is like a fashionable host, that slightly shakes his parting guest by the hand; and with his arms outstretched, as he would fly, grasps in the comer? Towards the end of the eighteenth century a writer of good repute—there were such in those days—after contemplating for some interval of time, wrote, "I saw the skirts of the departing year." He subsequently altered this to "I saw the train of the departing year." This imagery is no longer appropriate; trains have disappeared, skirts have become fine by degrees and beautifully less, and the trim ankle whose occasional appearance poets were wont to praise is now succeeded by that which recalls the story of the Prodigal Son. The year, whose departure we are seeing in our mind's eye, has been a year of quiet, uncertain and slow progress. This is as true of chemistry as of other spheres of human activity. No brilliant development, no spectacular theory comes into our mind, marking the year 1924 as a vintage year.

* * *

Nevertheless there is comfort to be derived from a close examination of our profit and loss account, our trading and manufacturing for the year under review. The Society's meeting in Liverpool was the largest, most important and best organised meeting of its kind. Dr. E. F. Armstrong terminated his successful years of office in a manner which was neither common nor mean. If we were the chairman of the company we should dilate on this, but we are merely the auditors. Why should a man be described as an auditor who in the driest words possible certifies the accuracy of accounts after freeing himself from responsibility by mentioning that the stocks have been valued by the company's officials? Everyone knows that whether you make a loss or a profit depends in most manufacturing businesses on how you value your stocks. Auditor, we suppose, means listener; when they have listened long enough they become directors. Every chartered accountant should have framed over his bed the opening words of Juvenal: "*Semper ego auditor tantum?*" Shall I always be merely an auditor? The next item which requires attention is the meeting of the Union Internationale at Copenhagen. This was one of the happiest and brightest of the meetings of that body. We are glad to mention that discussion has recently taken place in Paris on the revision of its statutes, and the committee appointed at Copenhagen will shortly be able to report progress. Wembley: when we think of Wembley we are almost inclined to re-write the earlier notes we have written. It is not wise,to yield too much to your inclinations; what we have writ is writ—would it were worthier! Wembley certainly is an achievement on which your chairman, Mr. Woolcock, is entitled to dilate in glowing periods and terms. The chemical exhibit at Wembley and the book "Chemistry in the XX Century" do stand high in the annals of British chemistry.

* * *

In the science of chemistry we are not competent to enumerate the most significant discoveries in their due order of magnitude. Dr. Aston has continued to investigate the anatomy of the atom, the division of the indivisible, and the explanation of the incredible; the manufacture of insulin has been made more economical, more scientific and more beneficial to mankind; the properties of hafnium are being gradually found out in Copenhagen; the manufacture of synthetic ammonia proceeds apace at Billingham; this country has agreed with Germany to continue the system of encouraging our own dyestuff industry by refusing to import foreign dyes unless a good case can be made out for an exception to that rule. Schemes for the graphic representation of polarities, valencies and chelate bodies adorn our pages at frequent intervals, and twice a month a small crowd assembles outside the Chemical Society's rooms in Piccadilly listening to Profs. La . . . ., Lo . . . ., Ro . . . ., and Si . . . . with some others, as they emerge into the street maintaining with no little heat their various opinions. There is, we fully believe, only one graphic representation of co-ordination, only one way in which this can be made manifest by any symbol visible to the

majority of chemists. It involves both plus and minus signs: these will be always equal in number; the time will have to come when the organic and the inorganic chemist, the organised manufacturer and the disorganised recipient of the benefits of chemistry, will agree upon a scheme for reduction of certain figures in a banker's book to a minus quantity and the insertion of a multitude of positive quantities into another account to be held on trust for chemistry generally. It is a mere case of induced polarity, of stereo-chemistry such as that celebrated recently in Holland and more recently in France.

* * *

Our relations with foreign Powers continue to be friendly: the recent election here and the recent elections in America and Germany have not produced a feeling of European dismay: the Dawes agreement will probably help us to secure a peaceable feeling in this distracted continent. The efforts of the radio-active people in Russia to produce a revolution here have not so far been successful, and are not likely to be successful. This is not a good country for an experiment of that sort: we are "not yet enslaved nor wholly vile, O Albion . . . social quiet loved thy shore, nor ever proud invader's rage or sacked thy towers or stained thy fields with gore." In this journal we cannot help reflecting to some extent the feelings of those we meet from week to week. Our chemical friends do not always talk to us in praise of dimethoxybenzaldehyde. Our literary pursuits sometimes take us far away from the substituted arylpyrazolones. Old Moore's Almanac is almost the last survivor of that combination of modern science and ancient astrology which distinguished the alchemist. This direct descendant of Paracelsus in his issue for the year 1924 predicted an important medical discovery as a leading feature in the brilliance of 1924; he was right, and in the Almanac for 1925 there appear two items, a full-page advertisement of that universal panacea "Yadil" and a note that their previous year's prophecy has been proved to be correct by the benefits conferred by that mixture upon suffering humanity. We trust that the next year's Almanac will prophesy the result of the libel action brought by the proprietors of Yadil against the *Daily Mail*, Sir William Pope and Professor Dixon. Unless some steps are taken to overcome the inertia of our courts and our litigants, we shall learn the decision in no other way. We digress; we must digress; unless we stray sometimes from our path we fear lest we find all individual dignity and power engulphed in Courts, Committees, Institutions, Associations and Societies, a vain speech-making, speech-reporting guild. We fear also lest we might in time, unless we strayed, fall into that error which Faraday condemned, that of accepting theories and usages as established merely because they have gradually become familiar. We ask our readers to forget us until the New Year and to think of us then as being as young, as innocent, as free from guile and as irresponsible as the year is young. Later, we may again become stately. God rest you, merry Gentlemen, let nothing you dismay!

DEVELOPMENTS IN THE BRITISH CHEMICAL INDUSTRIES DURING 1924

By REX FURNESS

The great wave of optimism which usually sweeps through industry with the advent of a New Year is often broken, all too soon, upon the rock of economic conditions into a dazzling but unsubstantial spray. From the commercial point of view, however, the year 1924 has not been too dismal, and the excess of exports of chemicals, dyestuffs and drugs over imports has been practically the same as in 1923, a year during a considerable portion of which trade was artificially stimulated by the Ruhr occupation. The chemical industries are so necessary to general industry that to supply home requirements would be satisfactory in itself, but, with the realisation of more stable conditions at home and abroad, it is possible to hope for an increase in our exports as well as in the home trade. It has been held in some quarters that the incidence of the Dawes scheme would react prejudicially against the chemical industries, for their voice was not heard in the discussions, but it may be pointed out that Germany is feeling palpitations in her chemical heart, if the statements of Dr. Duisberg of the Interessen-Gemeinschaft be taken at their face value. It is probable that individual hardships will be more than balanced by the general benefits which will come as a result of greater stability.

Wembley

Nineteen hundred and twenty-four has seen the realisation of the greatest scheme of advertisement for the chemical industries that has ever been attempted, and the display of the chemical section at Wembley is the seed from which a whole crop of trade will develop, provided adequate fertilisation be afforded in the shape of judicious advertisement in the chemical and trade press. Kinematograph films have been used more during 1924 for advertisement and propaganda purposes in the chemical world.

Synthetic Ammonia

The most outstanding development in the chemical industries has been the commencement of the manufacture of synthetic ammonia on a large scale at Billingham. Fixed nitrogen preparedness has become a dogma in the political and economic faith of modern nations in recent times, and it is thanks to the splendid work of Brunner, Mond and Co. that this country is able to depend upon "air-" fixed nitrogen supplies from the works of Synthetic Ammonia and Nitrates, Ltd., From 100 to 120 tons of ammonium sulphate per day have been manufactured throughout the year so that this company is already the largest individual producer within the ranks of the Sulphate of Ammonia Federation. Details of the process have not been made known, but it is considered to be a much improved type of the Haber-Bosch system both in respect of catalyst, hydrogen production, speed of ammonia formation and general plant equipment and control. Much of the ammonia solution resulting from the removal

of ammonia from the circulating gas stream by means of water, is converted into ammonium carbonate by means of carbon dioxide, produced within the main process. Reaction with calcium sulphate mined in the vicinity of the ammonia plant leads to ammonium sulphate formation, whilst there is a market for the precipitated calcium carbonate.

No praise can be too warm for all responsible for this great achievement, for the Billingham installation is the finest synthetic ammonia plant in the world, with the possible exception of the new German installation at Merseburg.

It is of interest to note that the production of sulphate of ammonia in this country has now overtaken the 1913 figure, but there is a large market available both at home and abroad.

Heavy Chemicals

General progress is evident in our heavy chemical industry, and the recent optimism in the cotton industry has reacted upon the former, so that home demands may be expected to increase. Exports during 1924 have risen above the very satisfactory 1923 figures, and to-day, in spite of heavily protected heavy chemical industries abroad, we are exporting more soda ash, bicarbonate, crystals and caustic soda than at any time. It is true that salt exports are not yet back at pre-war rates, but a steady improvement has been in evidence in 1924. Bleaching powder has again suffered due to the disappearance of the American, Canadian and Swedish markets, but India still calls for supplies, and more and more is wanted in Persia as the application of the hypochlorite refining process for petroleum products is being extended. This may be countered by the policy of home refining of Persian oils, now successfully established and increasing largely in dimensions. Any diminution of bleaching powder consumption in this country will be compensated for by increases in the consumption of liquid chlorine, and this product is now available in cylinders and tank cars. English makers of liquid chlorine are engaged upon intensive research and propaganda in respect of the use of their product.

Acids

Turning now to acid production, it must be recorded that synthetic nitric acid is now being made, in small quantities, by the catalytic oxidation of ammonia by Synthetic Ammonia and Nitrates, Ltd. Hydrochloric acid, no longer a by-product of the Leblanc process since the passing of this honourable method of alkali production after a century of service in 1923, is made specially by the action of sulphuric acid upon salt, whilst small amounts are made synthetically from chlorine and hydrogen.

Sulphuric acid, the life blood of industry, has been produced during 1924 almost at pre-war rates, although, on account of large plant additions during the war years, the percentage of plant in operation has not yet reached the 1913 figure of 85 per cent. A welcome decrease in the price of the acid has been observed, and manufacturers of sulphate of ammonia, and of superphosphate are amongst those most prominently affected by the favourable change.

It is impracticable to review the position of every chemical produced in this country, but special mention may be made of hydrosulphites and related compounds, the manufacture of which for the dye industry is now upon a secure basis. The value of home-produced bichromates has been more apparent in the 1924 returns, and cyanides and related compounds are regaining some of the ground lost by the inception of the process for making calcium cyanide from cyanamide at Niagara. It is to be regretted, however, that the efforts of the British Cyanides Co. to fix atmospheric nitrogen in the form of cyanide by the barium process have not been brought to full technical fruition during the year. Anyone who has experienced the trials of bringing in a new technical process will sympathise with the company, whose efforts have been unrelaxing and experimentally sound for years past. As a *quid pro quo*, however, a new product of value in rubber vulcanisation acceleration and in other directions has been produced by the British Cyanides Co. from gas works sulphocyanides, and successful marketing is announced.

A word must be accorded to the soap and glycerin industries, although little of absolute novelty has appeared during 1924. Messrs. Lever Bros. and their associated companies still pursue a policy of expansion, and factories in Scandinavia and Denmark have been opened this year. Efforts have not been without reward in the sale of British glycerin.

Artificial Silk

The production of artificial silk is definitely a chemical or chemical engineering process, and considerable developments are to be recorded. The viscose process is being further extended, and Messrs. Courtaulds have commenced the erection of a factory at Bushbury, Wolverhampton. It will cost a million and a half, and employ four thousand workers. Probably for the first time, the outside critic is able to look upon the progress of Celanese silk with satisfaction. Not only in production but in application in yarns, mixtures and specialities, and also in the important matter of dyeing has considerable progress been made. It is no secret that the inadequacy or inconvenience—or both—of the dyeing processes for acetate silk was responsible for the commercial difficulties experienced in earlier years. Nineteen hundred and twenty-four has seen the development of a new series of dyestuffs, which will supplement or, perhaps, entirely displace the famous Ionamines, those special acetate silk dyes discovered and produced by the British Dyestuffs Corporation. It has been found that a full range of dyestuffs, fulfilling many demands of fastness, resistance to washing, etc., can be readily applied to Celanese silk by the ordinary direct dyeing process if the dye particles have been sufficiently dispersed.

In the "S.R.A." series of dyestuffs, made by the silk manufacturers, a standard dyestuff itself is incorporated with a solubilising or dispersing agent. Sulphoricinoleic acid was the first dispersing agent used with success and has given its name to the series of colours—S.R.A. Available in the form of 10 per cent. pastes, they may be used without preparation and without change in dyeing method.

Dyes

This matter naturally leads to a thought regarding the dye industry itself. The British dye industry, of which the British Dyestuffs Corporation is an important part—but only a part—has shown its worth by steady chemical progress and the idea that Englishmen had not the temperament for the game should now be counted out. New and special dyes for artificial silk, new bacteriological stains, photo-sensitising dyes and so forth represent forward moves, and the whole progress of the dye industry is not that of an inconsequential plagiarist. On the commercial side, however, there are still difficulties and the reconstruction of the B.D.C. with alterations in the directorate are being significantly discussed. We may well wait the event without comment, but the negation of the policy of agreement with the Interessen Gemeinschaft must be noted. It is probable that the veto exercised by the British Government in this matter will meet with almost universal approval in this country. It has been shown that British research is of high standard and capable of supporting the super-structure of an industry, and it is difficult to see how such research could have continued had agreement with the I.G. materialised. The abandonment of research in this industry, with its reaction in many directions need not therefore be contemplated as a result of the workings of Anno Domini 1924.

The completion of the Colour Index in the early part of the year has given us a record of nearly 1500 dyestuffs and pigments, both natural and synthetic, which is invaluable. It is even more complete and correct than the Schultz Farbstoff Tabellen, and both the Society of Dyers and Colourists and Dr. Rowe, the editor of the work, merit the highest praise.

Fine Chemicals

The fine chemical industry, related so nearly to the dyestuffs industry, has witnessed progress in the manufacture of drugs, pharmaceuticals, photographic chemicals, perfume synthetics and so forth, but pride of place must be given to the successful production of insulin upon a large commercial scale. Insulin, from the pancreas of the ox, is unstable in the presence of alkali and at relatively low temperatures. It is very easily destroyed by tryptic fermentation and its isolation in a relatively pure state in technical quantities was a problem demanding high ability in its solution. The efforts of British chemists and manufacturers have brought down the cost of insulin treatment during the last year or so from pounds to shillings per week. Insulin is now available to all who require it and the achievement is illustrative of the progress which our fine-chemical industries have made.

The predictions of King in the matter of the constitution of the celebrated Bayer 205 for sleeping sickness treatment have been substantiated this year by the discovery in France of Fourneau 309, and when the material has been fully tested, it will undoubtedly be made in English laboratories.

Beet Sugar

The foundations of a home beet sugar industry seem now to be well laid, for, in addition to the factories already producing at Kelham, Cantley and Colwick, six new works are to be erected and subsidised by the State. The work of survey, preparation and building has already commenced in several instances, and production during the 1925 season seems assured in at least one factory. During 1924, the area of land under beet cultivation has been largely increased, and work has been actively continued upon the question of the commercial production of the best type of seed.

Absorbent Carbon: Inorganic Gels

Active decolorising charcoals have been made in this country this year, and the quality is claimed to equal that of Dutch, German or American chars. These substances will find application, not only in sugar refining, but also in the decolorising of oils and fats and other materials, whilst they have a future as absorbents for solvent vapours from air or gas. Thus, benzol may be extracted from coal gas or coke-oven gas more economically than by the old oil-scrubbing processes, and solvent recovery in the rubber, and explosives and other industries is cheapened. In this connexion the inorganic gels, such as silica gel, etc., claim equal attention, and silica gel and an aluminosilicate gel are now made in this country. The latter, "Doucil," also possesses high base exchanging properties, and its use in water softening is spreading, as its superior powers are realised. Silica gel has been used in this country in refining petroleum products, following its success in the States.

Smoke Abatement

Smoke abatement is a matter which concerns the chemical industry directly and indirectly, and much propaganda work has been carried through during 1924, so that both public and manufacturers are beginning to take a greater practical interest in methods for its realisation. Smokeless fuel production has increased and newer processes show further development. Corporations such as those of Glasgow and Nottingham have become producers of smokeless fuel, and it is likely that this move will continue, for such bodies are ideally placed for disposing of by-products in the shape of rich gas and complex tars. The value of low-temperature tar has, however, not been definitely assessed either scientifically or commercially, and much work remains to be done. The burning of powdered fuel under boilers generates less smoke than when ordinary stoking practice is employed, and it is gratifying to note that the undoubted economies of the process have led several executives to put down installations this year. The Birmingham municipality, a Metropolitan electric power supply company, and the Synthetic and Nitrates Ammonia Co. may be cited as important instances.*

* A large and important series of papers upon fuel and kindred problems has been given at the 1924 World Power Conference, and is now available in print.

Chemical Engineering

Britain has often been charged with neglecting the manufacture of efficient chemical plant and the training of capable chemical engineers. The activities of our various societies during the year should clear away the latter taunt, whilst the fundamental research work upon production and standardisation of plant demonstrates that the manufacturer of apparatus for the various unit processes of chemical engineering practice is alive to realities. Production of excellent plant is well maintained, and it is of interest to note that British chemical plant has actually been exported to Germany in 1924, the contract being, in at least one instance, a "repeat" order.

It is perhaps invidious to particularise, but mention may be permitted of the Premier mill or colloidal mill, the stream line filter of Hele Shaw, jacketed pans, stills, filtering and crystallising apparatus and evaporators. In addition, British oil extraction and expression apparatus is second to none.

The Societies

The activities of our many societies and organisations have been well maintained, and the distinct signs of greater co-operation and ultimate fusion in some way are encouraging. The exhibit of the industry and science of chemistry at Wembley, organised and arranged largely as a result of the activities of the senior Societies and The Association of British Chemical Manufacturers, may be paid the compliment of mere mention here, for its value, interest and comprehensive character are surely stamped upon the memory of every reader. "Chemistry in the Twentieth Century," and the series of popular pamphlets have had a gratifying reception, and mark a forward move in the essential matter of placing the science and industry in their rightful perspective in the eye of the educated public.

Organised Research

Although no epoch-making discovery is directly foreshadowed in the reports of the various Boards under the Department of Scientific and Industrial Research, there is much evidence of solid progress in fuel, oils and fats, food preservation, cotton, leather, glass, etc. problems. The whole scheme of collective research has been criticised as being unsuited to the English temperament which is essentially individualistic, but there is no doubt that much useful work has been accomplished. Advocates of the idea of team work have not been wanting, and the address of Sir John Russell at the Toronto B.A. Meeting presents an eloquent defence of the system.

Other Matters

The final report of the Committee on the question of preservatives and colouring matters in foodstuffs is so definitive as to foreshadow immediate legislation.

Finally, a few points of interest—possibly selected arbitrarily or tinged with personal prejudices—may be noted. The year has seen the celebration of the centenary of the discovery of cement by Joseph Aspden, of Leeds, and American and English manufacturers of cement have fittingly paid tribute to the discoverer. Rubber latex has been increasingly exported from British dependencies, but relatively small amounts have been worked up in this country. New and improved accelerators of vulcanisation have been put upon the market, and general progress in the rubber industry is evident.

Agricultural research continues to examine the problems of soil fertility, fertiliser and insecticide production, the microbiology of the soil, artificial farmyard manure manufacture, soil conditioning and plant physiology, and propaganda work amongst farmers is being pursued with greater intensity.

The hydrogenation of oils upon a technical scale has temporarily disappeared, but the plants in being provide an effective economic safeguard against unwarrantable rises in price of solid fats. Research into problems of oil and fat chemistry—"a neglected chapter"—was foreshadowed by the remarks of the late President of the Society of Chemical industry at the annual meeting.

Power alcohol has been made upon a larger scale as the result in part of the operation of the new factory on the Humber, which is fermenting molasses.

The year as a whole has been one of steady untheatrical progress within the various branches of the chemical industry, and the part which chemistry plays in the social and economic progress of the community has perhaps never been so widely realised as in the closing months of 1924

SYNTHETIC AMMONIA IN ITALY

Nitrogen fixation continues to develop in Italy, and it is estimated that by 1926 the total capacity of the Italian factories will reach 12,000 metric tons of nitrogen annually. Details of the plants now working or to be completed are as follows:—The Societa Italiana Ammoniaca Sintetica, which uses the Casale process, is producing 3 m.t. of ammonia daily at Terni. and is building a plant at Nera Montoro, which will shortly be producing 7 to 8 t. of ammonia daily. The old Fauser plant of the Società Elettrochimica Novarese at Novara, with an output of 1 t. ammonia daily. has been replaced by a plant to produce 15 t. ammonia daily. and the new Fauser plant of the Montecatini company at Sedico Bribano (Belluno) will produce 2 t. ammonia daily. Plants are under construction at Bussi by the Società Azogeno (Claude process, 7 t. ammonia daily), at Coghinas in Sardinia by the Società Sarda Ammonia e Prodotti Nitrici (10 t. ammonia daily), at Marlengo, near Merano, by the Società Alto Adige Ammonia (50 t. ammonia) daily, and a large plant at Cotrone will begin work in 1926.

The Casale process has been adopted in France, Spain, Germany, Belgium, the United States and Japan, whilst the Fauser process is to be used in a new plant at Luz in the Pyrenees, and it is understood that a new process developed by Carrara and Zorzi at Milan is to be applied on an industrial scale.—(*G. Chim. Ind. ed App.*, October, 1924).

THE CHEMICAL INDUSTRY IN 1924

The world has not yet recovered from the extreme poverty caused by the enormous waste of the Great War and during the past year Chemical Industry, in common with most other industries, has suffered from this cause. It cannot be denied, however, that a slow but steady recovery is taking place and the past year does not compare unfavourably with its predecessor in the amount of business which has been transacted The demand for, and consumption of chemical products depends to a great extent on the amount of activity prevailing in other industries, among which the textile, and iron and steel trades are of the utmost importance. The depression which has prevailed in these two typical industries for the greater part of the year has naturally affected the home market for chemicals. Latterly, however, the prospects of cheaper cotton, the adoption of longer working hours in the cotton trade, together with renewed activity in the iron and steel industry and the establishment of more settled political conditions have given rise to a feeling that the future is much more hopeful than it was. The industry has not been affected by strikes as much as in previous years and the number of working days lost has been little more than half those lost during the previous year. In the autumn the unemployed male workers in the industry amounted to rather less than 10 per cent. of the total. During the summer some 22,000 workers in the heavy chemical industry received an advance in wages which was estimated to cost the industry about £300,000 per annum.

The production of sulphuric acid provides a very good index of the state of the chemical industry as it does, indeed, of trade in general. Calculated as 70 per cent. H_2SO_4 the output for the year ending June 30, 1924, amounted to 1,272,000 tons, corresponding with 63 per cent. of the plant capacity used. This shows a slight increase over the output for the previous year, but is still nearly a quarter of a million tons less than in pre-war times. Prices have ranged from 70 per cent. to 100 per cent. above pre-war although costs of production have been relatively much higher, probably at least 150 per cent. above pre-war. Production has been adversely affected by the depression in the superphosphate industry which, together with the manufacture of sulphate of ammonia, normally consumes half the output. A study of the statistics relating to the raw material used in the production of sulphuric acid during the past year and in pre-war times is very interesting. The figures are as follows :

Raw materials used	1913 tons	1923–24 tons
Pyrites	800,000 ..	350,000
Spent oxide	110,000 ..	148,000
Sulphur	3000 ..	66,000

The increased use of brimstone for high quality acid is very noticeable, about 22 per cent. of the acid produced during the past year having been made from this raw material compared with only 1 per cent. in 1913. An increasing quantity is also being made from the sulphurous fumes resulting from the smelting of zinc.

British heavy chemicals have always been predominant in the world's markets and a steady export business has been going on continuously throughout the year. On the whole prices have kept very steady indeed, although there have been a few fluctuations. Salt cake, for instance, which at the beginning of the year was valued at £4 10s. per ton was reduced to £3 10s. in the early summer and has maintained that figure ever since. Lead products have been particularly erratic owing to the fluctuations in the price of the metal. In the early part of the year, the price of brown sugar of lead for instance advanced from £42 to £47 per ton and afterwards declined again to the old figure. Latterly, the more important non-ferrous metals have been advancing in price, and products made from these have followed suit. White arsenic has been conspicuous for its steady decline in price throughout the year from about £70 per ton in January to £35 in December. This fall has been due both to the smallness of the demand, particularly from America, and to the very keen competition of the Japanese product.

Bleaching powder has been one of the quietest of the heavy chemicals due, no doubt, to the slackness in the textile industry. The price, however, has been fairly well maintained at about £10—£11 per ton. An interesting development has been the export of considerable quantities to Persia for use in the refining of petroleum by the hypochlorite process.

Steady business has been done in borax and boric acid, and the price of the latter was reduced in the summer by about £3 per ton for all grades. Cyanide products have suffered from American competition during the year, and sodium prussiate, for instance, has declined from 7d. to 4d. per lb. An encouraging feature has been the resumption of the manufacture of formaldehyde in this country, although the market has not been a very active one.

The market for wood-distillation products began the year very well with a good demand for acetates in particular. As the year went on, however, the industry began to suffer from American competition, and grey acetate of lime, for instance, declined from £22 per ton to about £14. Latterly, however, conditions have improved and a stiffening tendency has been in evidence.

As mentioned above, the superphosphate industry has been depressed, mainly owing to competition from Continental products produced with cheap labour, low taxation costs and helped by depreciated exchanges. Temporary relief was afforded during the spring by the improvement in French and Belgian francs which resulted in a decrease of imports at very low prices. Nevertheless, the consumption has been only 75 per cent. of the pre-war figure, and the industry is only slowly recovering the markets lost during the years following the war when exports were prohibited. The trade has been free to export for two years now and conditions generally are more favourable. The stabilisation of foreign exchanges, however, is vital to this industry.

The year has been a prosperous one for the sulphate of ammonia manufacturers, the production for the year amounting to over 400,000 tons, of which 65 per cent. was exported. The average

price for all deliveries both for home and export was £13 5s. 11d., compared with £15 0s. last year. The manufacture of the synthetic product is now firmly established in this country by Synthetic Ammonia and Nitrates, Ltd., who are now the largest individual makers of ammonium sulphate in this country.

With regard to tar products, the year on the whole has been very quiet and rather disappointing in spite of the restriction of output due to the small demand for coke by the iron and steel industry and the consequent closing down of some of the coke ovens. Cresylic acid has been the steadiest feature in the section, and the price has remained substantially unaltered at 2s. 1d. per gallon. Pyridine has been conspicuous because of its demand for methylating purposes, but the price has been erratic, varying between 24s. and 14s. per gallon. Heavy pyridine gradually increased in value throughout the year from 8s. to 12s. per gallon. Carbolic acid has been most disappointing, and has met with very little demand. The crude acid has declined from 2s. 9d. to 1s. 8d. per gallon, and the crystals from 1s. to less than 6d. per lb. Benzole, as might be expected, has generally followed the market for petrol, and was advanced in price in the spring and reduced in September. Recently the price has again been advanced, while the benzole mixture for motor purposes has been kept at the same price to compete with petrol although modified slightly in composition. Supplies of benzole have been none too plentiful. Solvent naphtha has also fluctuated considerably, rising to over 1s. 6d. per gallon in the spring, falling to about 11d. in the autumn, and again recovering to about 1s. 6d. during the past few weeks. Perhaps the most important feature among tar products has been the great fall in the price of pitch, which has been almost continuous throughout the year from about 100s. per ton in January to about 40s. in November. A reduced export demand and considerable imports of American pitch for patent fuel manufacture in South Wales have no doubt contributed to this decline in value.

THE BRITISH DYESTUFF INDUSTRY IN 1924

In spite of the continued depression in colour consuming industries, and consequent curtailed demands for dyestuffs, there is no evidence of diminished effort on the part of the dye makers. On the contrary, increased internal competition has been apparent, with the result that the general level of prices has been constantly, if gradually, lowered.

Keen competition must inevitably result in increased efficiency in production, which implies not only improved yields but also purer and better products, and during the year marked improvement has manifested itself in already existing products, in the direction of brilliancy of shade, solubility, fine paste products for textile printing, and so on.

Perfection of existing dyestuffs, in preference to the making of new ones, has not infrequently been urged as sound policy by consumers. In addition to progress on these lines many dyes not hitherto made in this country—some twenty-five, at least, distinct and essential types belonging to various categories—have been put on the market during the last twelve months, in quality equal to that of the foreign products which they have replaced.

It is not easy to form, at any given moment, a reliable estimate of the value of research in progress, but the indications are that this important branch of work is being prosecuted with no little vigour. Howbeit much criticism has been provoked by the drastic curtailment of research staffs in certain sections of the industry. Considerable work has been expended upon dyestuffs for cellulose acetate silk, and the problem of successful commercial dyeing of this material is much nearer solution than it was a year ago. This country has probably contributed more to the world's achievements in this direction than any other, though Germany and Switzerland have been by no means inactive. Following upon the greater understanding of the nature of the dyeing process in relation to the new fibre, the evolution of a more or less general method has taken the line of presenting insoluble colouring matters of widely diverse chemical constitution in such a form as to be assimilated by the cellulose acetate. Thus the omega sulphonic acid and bisulphite compound processes have been succeeded by the more generally applicable colloid dispersal method whereby insoluble dyestuffs are incorporated with sulphoricinoleic acid, or other disperse colloid, which renders them readily "accessible" to the cellulose acetate fibre. Doubtless this new method as yet only marks the beginning of another era in textile dyeing.

As a general rule the quality of the dyestuffs manufactured in Great Britain is admittedly good. The mind of the consumer is, however, much occupied with the question of prices ruling, and is actively directed towards effecting reductions.

The negotiations reported to have been taking place between the national company and the German Interessen Gemeinschaft have not fructified, the President of the Board of Trade having announced a few months ago that he would be compelled to withhold his sanction from the proposed agreement.

THE BRITISH FINE CHEMICAL INDUSTRY IN 1924

For those engaged in the Fine Chemical Industry in this country the year now closing has been one of great interest. Unusually frequent changes of Government have not tended to stabilise trade conditions, and many of the confident hopes expressed twelve months ago of greater business internationally and within the Empire have failed to materialise; but quiet, steady progress in several branches of the industry has undoubtedly been achieved. New buildings have been erected, departments extended, processes devised or revised, labour and output increased, and in consequence the industry is more firmly and broadly established than ever before, and more adequately equipped to tackle new problems, or greatly increase demand, as occasion arises.

Wembley

Every visitor to the Chemical Hall in the Palace of Industry at Wembley learned in varying degrees to appreciate the importance to the nation and to the individual of a strong and flourishing chemical industry. Professors and teachers discovered, sometimes to their evident surprise, that analytical reagents and microscopic stains of unimpeachable purity could be obtained from British manufacturers. Students and traders were obviously deeply interested in the displays of organic and inorganic chemicals, and even the members of the public wending their way from the water-tap suspended in mid-air, to the fountain composed of "real soap-suds," gained some fleeting impression of medicinal and pharmaceutical chemicals produced in home factories.

Output

The manufacture of well-established chemicals in general demand continues to make satisfactory progress. Alkaloids and their salts, such as atropine, pilocarpine, and cocaine have been placed on the market at competitive prices. Salicylic acid, sodium salicylate, and aspirin are being produced equal in quality and appearance to any imported consignments. Formaldehyde, paraformaldehyde, and paraldehyde, all of British origin, are now available in ample quantities. Acetanilide, chloral hydrate, and vanillin have attained a steadily increasing output. Calcium lactate, barium sulphate (for X-ray examinations), and sodium benzoate, each of a higher degree of purity than any produced elsewhere, are being readily purchased by discriminating buyers. Staple lines, such as sodium sulphate, magnesium sulphate, and calcium phosphate, have been manufactured on a scale exceeding any previous record.

Prices

Increased production here, coupled with higher costs of manufacture abroad and the general gradual return to more normal rates of exchange, have resulted in greater uniformity of prices, and less fluctuation in values. In this connexion it is interesting to compare quotations for a dozen typical fine chemicals in 1914, during the period of the war and to-day.

	1914		War period		1924	
	lb.		lb.		lb.	
	s.	d.	s.	d.	s.	d.
Acetanilide		10	8	9	1	11
Acid salicylic ..		11	20	0	1	5
Aspirin	1	11	48	6	3	0
	oz.		oz.		oz.	
Atropine sulphate ..	21	9	120	0	12	6

The figures demonstrate that the value of many chemicals has reached a reasonable economic level when increased taxation, cost of labour and transport charges are taken into account.

The Future

Faith has been defined as "a capacity for believin something which you know cannot possibly be true, but with a Government in power, backed by th largest majority of modern times, the fine chemic manufacturers of the country would appear to hav a sound and solid basis for faith in the industry an to be in a position to develop trade and decreas unemployment, provided that it is found possibl to effect a settlement in the matter of inter-Allie war debts, and that the Safeguarding of Industrie Act can be rendered more elastic and adaptable t prevailing conditions. In such circumstances event may justify all concerned in looking to the comin year as likely to yield a period of progress an prosperity.

CHEMICAL ENGINEERING DURING 1924

By S. G. URE, M.A., B.Sc., M.I.Chem.E.

The year which is now closing has many interesting features for the chemical engineer and chemical plant manufacturer. On the educational side one welcomes most heartily the opening of the new Chemical Engineering Laboratories in London, at the University College. The new laboratory, which forms an important addition to the existing laboratories in this country in which the subject is taught, is part of the memorial to the late Sir William Ramsay, at one time Professor of Chemistry in University College. Those who are responsible for the venture are to be congratulated on deciding on this form of memorial and on having obtained the support and co-operation of a number of firms well known in chemical industry. Also of an educational character, and also of very great importance to industry, was the World Power Conference held during the summer at the British Empire Exhibition. Representatives and delegates from over thirty countries were present, and papers were read which covered a very wide field, including subjects of special interest to chemical manufacturers, such as power in electrochemistry and electrometallurgy. The question of cheap power is of vital importance to all industries, and the work which was done in this connexion at the Conference should prove of the greatest value. Whilst dealing with the subject of power production, mention may be made of the inauguration, towards the close of the year, by the British Aluminium Co., of their Lochaber Hydro-Electric Power scheme. The magnitude of this undertaking may be realised when it is stated that it will take from five to six years to complete the work, which includes harnessing the waters of Lochs Treig and Laggan, as well as the Rivers Spean, Treig, and Spey. This is the largest hydro-electric power scheme so far undertaken in this country, and will have cost on completion about £5,000,000.

Many power stations and factories in different parts of the country are adopting the pulverised system of boiler firing and are erecting plants suitable for this purpose. The pulverising of the fuel is usually effected by mills of the Raymond or Fuller-Lehigh types. Gas firing of boilers has also received some attention, and new plants are being erected in fac-

tories to produce gas for this purpose. Another method of firing which is receiving attention is that adopted in the Brunler internal-combustion boiler, in which the fuel is burned under the surface of the water, the products of combustion passing over with the steam generated. For this type of boiler a very high efficiency is claimed. Articles on the steam accumulator, an important adjunct for boiler plants in chemical industry, have also appeared in the technical press during the year. Important extensions are being made at various gas works and collieries, in some cases with the object of producing smokeless fuel, and in others simply with a view to increasing the capacity of the works for gas production.

The lessons impressed on the world by the shortage of nitrates during the war have resulted in considerable attention being directed towards nitrogen fixation, and developments have taken place in this province during the year. At Billingham-on-Tees the Synthetic Ammonia and Nitrates, Ltd., have started up their new factory, which is the only plant outside of Germany in which the Haber process has, so far, been worked with success. Nearly all the great countries in Europe and North America have been developing nitrogen fixation during the year. In Italy, for example, plants are being designed, or are in course of erection, which will raise the annual production to 20,000 tons of fixed nitrogen in the form of ammonium sulphate, an amount which is more than double the internal consumption of that country. The Casale process, using hydrogen produced by Fauser electrolysers, seems to be the favourite method adopted in Italy, although some plants are being erected in which the Claude process will be used.

As the result of the protection afforded by the late Government, and continued by the present, in the form of a subsidy to the beet sugar industry, considerable developments are taking place. Already several new companies have been formed, and no time has been lost in acquiring sites and getting ahead with the erection of the factories, which cost between £200,000 and £300,000 each. One of the conditions under which this subsidy is granted is that at least 75 per cent. of the plant and machinery shall be of British manufacture. This should ensure that a considerable part of the costs of each factory should go in the form of orders to our engineering and allied trades. In passing, mention may be made of the erection at Belfast of a new oxygen plant, the property of the Irish Oxygen Co., which is closely associated with the Liquid Air Co. of London. This factory is conveniently situated to the great shipyards of the town, and will give employment to between two and three hundred men. A new plant, in which for the first time in this country silica gel has been used in oil refining, has been brought into operation during the year, and seems to have given every satisfaction to its owners, the Medway Oil Refinery Co. An interesting new material is "Proderite," a pitch concrete formed of vertical retort tar and silicious material, which can be cast into pipes or moulded and may be reinforced like ferro-concrete. It is capable of resisting the action of hydrochloric acid at temperatures up to 110° C.

Another feature of the year was the British Empire Exhibition, at which a considerable amount of plant and machinery suitable for chemical works was on view. Most of this was housed in the "Palace of Engineering," but many very interesting plant exhibits were to be found in various other halls and pavilions. The scattered nature of these exhibits, both in the "Palace of Engineering" and elsewhere, whilst bringing to the notice of those interested numerous other machines, involved a considerable waste of time in finding particular exhibits, and did not tend to impress the average visitor with either the magnitude or importance of chemical engineering. Practically every type of machine used in chemical works was on view, and the quality of the goods exhibited showed that the home-manufactured product was of sound design, made of good material, and revealed high-class workmanship.

PROGRESS IN STEAM GENERATION DURING THE YEAR

By DAVID BROWNLIE, B.Sc., M.I.Chem.E., A.M.I.Min.E.

A striking advance has been made during the year in what is now, at last, being recognised to be the highly important science of steam generation. Considering that about 500,000,000 tons of coal and lignite are being burned per annum in the stationary land boilers of the world for the one operation of making steam, and probably over another 150,000,000 tons in locomotive and steamship boilers, it is surprising the subject has been neglected for so long. Also it is still more staggering that Great Britain, for example, which is no worse than any other country, still goes on squandering about 20,000,000 tons of coal per annum in boiler fireholes for want of scientific methods that are little more than elementary common sense. However, great progress is to be recorded so far as the large water-tube boiler is concerned, and it is the object of this contribution to indicate the advances that have been made, during the past 12 months, particularly in so far as interests the chemical engineer and the technical chemist.

Progress in Power Station Practice

First of all, looking at the whole subject of steam generation from the point of view of a broad general survey, perhaps the most striking fact is that a number of boiler tests have now been carried out with both pulverised fuel and mechanical stoker firing giving over 92 per cent. boiler plant efficiency, and we seem to be within sight of 90 per cent. continuous efficiency all the year round, that is, including light running at night and during the week-end, together with stand-by losses. It is perhaps not easy to grasp the amazing character of this achievement. The average chemical works boiler plant, as with most other industries, is running at a continuous efficiency of less than 60 per cent., and only a small percentage of ordinary large electricity stations reach 75 per cent., the vast majority being less than 70 per cent., whilst if all the boiler plants

of Great Britain were by some miracle raised to 90 per cent. efficiency, the saving would be about 32,500,000 tons of coal per annum, that is, say, £40,000,000. Pulverised fuel firing is largely responsible for this success, but whilst it first rendered possible the 85 per cent. continuous efficiency boiler plant, as at Lakeside, Milwaukee, mechanical stoking has now made remarkable progress, and the struggle for supremacy between the two systems is keener than ever.

Mechanical Stokers

Developments during the year with mechanical stoking have largely been in the direction of air heating, the invention of the "Murray" water-cooled combustion chamber side walls, and the great size of individual units. Thus a single travelling grate stoker can now be constructed 24 feet wide and over because of the use of the flat suspended firebrick arch, that is essentially the use of special firebrick blocks attached to steel girders instead of the old sprung arch, which, under the conditions of mechanical stoking, cannot be made more than 8 or 9 feet across.

The great increase in size now possible with the multiple retort type of stoker is well indicated by the new Kearney electricity station of New Jersey, U.S.A., in which multiple retort stokers are being installed to burn no less than 30,000 lb. (13½ tons) of coal per hour each on normal running, or about 15 tons per hour overload, corresponding to an evaporation of nearly 300,000 lb. of water per hour under average conditions. The "Murray" water tube walls at the Hell Gate power station, New York, have resulted in tests showing over 92 per cent. boiler plant efficiency, equal to the latest pulverised fuel figures.

Pulverised Fuel

Pulverised fuel firing is progressing rapidly and a number of installations are now in hand for Great Britain, noteworthy being the equipment for Messrs. Synthetic Ammonia and Nitrates, Ltd., whilst the power station plants include Willesden, St. Pancras, Birmingham and Derby. In the United States many installations have been started up and new ones ordered. Thus Lakeside, Milwaukee, and the Ford plant at River Rouge, Detroit, have been doubled in size, whilst Cahokia, St. Louis, has been set in operation and the installations of the new Trenton Channel Station, Detroit, and the Cleveland Electric Supply Co. will soon be ready. Perhaps the most remarkable development of pulverised fuel firing is the almost completely automatic boiler plant in which the supply of pulverised fuel and air is controlled by the flow of steam in the main, operating through steam meter mechanism. This method of firing has rendered possible the monster boiler of which the latest example is at the Allegheny County Steam Heating Co., which, fired with "Lopulco" pulverised fuel, has 32,750 sq. ft. heating surface and will evaporate comfortably 400,000 lb. of water per hour. This is equal to about 60 "Lancashire" boilers 30 ft. by 8 ft.

The general tendencies in pulverised fuel firing are, first, the recognition of the fact that the natural moisture of the coal substance is no obstacle to efficient pulverising, but the trouble is the external moisture, so that it is only necessary to dry down to about 3—5 per cent. The ideal of pulverising is now to obtain absolutely even particles, so that 95 per cent. will pass through 100-mesh, and not so much division so that 65 per cent. will pass through 200-mesh, and 90 per cent. through 100-mesh. Further, both air heating and the "Murray" water-cooled side walls are now being used, as well as air-cooled walls and the water screen.

Boiler Feed Treatment

The efficient treatment of boiler feed-water has received more attention, and the huge boiler of 250,000 lb. evaporation per hour and over has only served to emphasise the deleterious effect of small amounts of oil, mud, apparently harmless inorganic salts such as sodium sulphate, and dissolved air and carbon dioxide, apart, of course, from common salt and calcium and magnesium salts. Several new zeolites have appeared and the design of "degassing" or de-aerating plant has improved, whilst an interesting development—although not directly connected with steam generation—is the continuous treatment of the cooling water of steam engine and turbine condensers with a trace of chlorine gas to prevent the growth of organic deposits on the condenser tubes. Further, also, much attention is being given in the United States to the use of carbon dioxide for partially dissolving and loosening boiler and pipe scale.

Action of Caustic Soda on Boiler Plates

The Massachusetts Institute of Technology have continued their investigations into the cause of "embrittlement" or "season cracking" of steam boiler plates. This only takes place at about 160 lb. pressure or over, and is apparently due to the action of caustic soda, formed by the decomposition of sodium carbonate, on the normal impurities present between the steel crystals of the boiler plate, which are dissolved out, allowing bubbles of hydrogen to penetrate and extend the crevices. The remedy is no excess of soda ash in the feed-water, and in this connexion the National Electric Light Association of New York has just published some amusing figures giving the detailed analyses of 15 boiler compositions. These almost all contain caustic soda or soda ash, and, in one case, the price charged was equal to seven dollars per lb. for soda ash!

Flue Gas Analysis

The principle of continuous flue gas analysis is also making good progress, and the modern practice is to use duplex machines which give a continuous record of carbon dioxide and also either carbon monoxide and unburnt products or excess oxygen. A very interesting new absorbent for oxygen has been produced by Louis F. Fieser, and consists of an alkaline solution of sodium hydrosulphite with a small amount of anthraquinone-β-sulphonic acid to act as a catalyst, 30 g. caustic soda, 40 g. hydrosulphite and 5 g. of the catalyst being made up to 250 c.c. This is stated to be a big improvement on

the use of phosphorus sticks, and, of course, the messy alkaline pyrogallol. For continuous determination of carbon monoxide the general principle is to burn by means of an electric coil and determine the increase in carbon monoxide.

High Steam Pressures

The use of higher and higher steam pressure continues to be adopted, and we are not so very far off red-hot steam pipes, that is, a temperature of 1000° F. (540° C.). During the year, full details have at last been published of the remarkable North Tees plant running at 475 lb. pressure, and quite a number of boiler plants will soon be running at over 500 lb., including the new Crawford Avenue station at Chicago at 600 lb. Experimental boilers are also being constructed in Germany and the U.S.A. to work at 1000 lb. pressure and over. Thus one design has drums that are steel forgings no less than 4 in. thick. Other striking new boilers, entirely different from ordinary designs, are the "Blomquist" revolving tube boiler at 1500 lb. and the "Brunler" boiler using a flame under water. The most remarkable of all, however, is the "Benson" super-pressure generator, already described in these columns, operating at 3200 lb. pressure and the "critical conditions," when water is converted into steam at the same volume without the absorption of latent heat, allowing of over 35 per cent. thermal efficiency from raw coal to the switchboard. Of the greatest interest is the "Emmet" mercury boiler and turbine, using mercury instead of water in the generator, and driving the turbine with mercury vapour in place of steam.

Sulphur and Ash Fusibility

Attempts have been made to determine the fusibility of ash in large-scale furnace work by determination of the sulphur content of the coal in the laboratory. The results are not decisive, but it is evident that, roughly speaking, the higher the sulphur content the lower is the fusibility of the ash. If 2500° F. (1400° C.) is taken as the dividing line between a good and a bad ash, very few examples are known of a coal with a high sulphur figure giving a good ash. Thus, out of 1163 coal samples, only 16 contained less than 0·5 per cent. sulphur, and all these had an ash of over 2500° F. melting point.

Other Developments

Many other interesting developments in connexion with steam generation are to be recorded during the year, including the proof that sulphur in coal does not affect concrete bunkers, the use of steam pipe ranges over 3500 ft. in length with little or no condensation loss, the production of several new steam meters and a radiation pyrometer, the use of steam-jet mechanical boiler-flue cleaners, the utilisation of waste gas and heat from coke-oven plant and also the sensible heat in the coke itself, the introduction to Great Britain of the "Ruths" steam accumulator, a new household refuse utilisation plant at Birmingham, and improved boiler and pipe coverings, including the use of blue asbestos and new compositions to place next to very high pressure piping.

THE PROGRESS OF CHEMICAL INDUSTRY AND TRADE IN FRANCE DURING 1924

By MAURICE DESCHIENS

The chief features noticeable in the French coal industry (an industry which is so fundamentally important to chemical industry) during recent years, are the increased production and the discovery and development of new deposits. In 1913 the production averaged 40,600,000 metric tons yearly, compared with a consumption of 63,000,000 m.t., or an average daily production of 136,147 m.t. (1913). Passing over the war years, daily production in January, 1923, was 121,064 m.t., after which it rose to 144,680 t., in January, 1924, and 151,982 t. in October, 1922. A great part of this increase is due to the reconstruction of the Nord and Pas de Calais mines, whose daily production has increased from 85,000 t. to 90,000 t. From these figures, and particularly from the output of 4,103,516 t. in October, 1924, it appears probable that the production will approach 60,000,000 t. per annum in 1925.

The consumption of coal remains heavy, and the imports in October, though slightly less than in previous months, were still large — *i.e.*, 2,070,983 t., of which 1,012,155 t. came from Great Britain. Similar important improvement is noticeable in ordinary and metallurgical coke. Coke produced by the coal mines, excluding that from metallurgical works, totalled 230,694 t. in October, against 131,994 t. in January, 1923, and 222,979 t. in March, 1924. This increase was due to the installation of numerous new batteries of coke ovens.

In the coke industry three chief tendencies are noticed, the object being to produce metallurgical coke from fat coal and recuperate the largest possible quantity of distillation products capable of being used as motor fuel. One tendency is to carbonise for a short period in narrow, long and high ovens made of silica bricks. Another tendency is to heat to 300° as quickly as possible, increase from 300° to 600° by 50° each hour, and then arrive rapidly at 800°; and the last tendency, the method of the domanial mines of the Saar, is to treat fat coal with 32 to 38 per cent. volatile matter in special retorts at low temperatures, and then to mix the semi-coke obtained with four times its weight of fat coal for carbonisation in the usual manner in an ordinary oven.

The shortage of French metallurgical coke tends to diminish, despite the import of 356,353 t. in October, 1924. French metallurgy now controls practically half of the world's reserves of iron ore, and extracts over 30,000,000 t. yearly. Of the 221 blast furnaces in existence, 135 are alight, the production of cast iron and steel in October, 1924, being 659,926 t. and 609,122 t., respectively. The number of blast furnaces alight is still increasing, and the production during 1924 will be found to have increased by some 60 per cent. compared with 1923. There is an interesting increase in the manufacture of steel in the electrical furnace.

After the war period, recent years, and especially 1924, show a veritable rebirth of chemical industries,

which have completely changed the economic physiognomy of France. The various sulphuric acid works utilising either the chamber of the contact processes (the two processes often being used in the same factory) can produce 2,000,000 t. of acid of 53° Bé yearly, compared with a consumption of 1,500,000 t. Despite the existence of French deposits, supplies of pyrites are expensive, especially when of Spanish origin, 500,000 t. being imported from all sources. The situation as regards nitric and hydrochloric acids, soda and sodium salts is normal, the consumption of soda being roughly 700,000 t., which allows of exportation. A new soda factory, independent of the large groups of manufacturers, has been installed at Monguerre.

The production of mineral phosphates in France, Tunis and Algeria, was 276,500 t. in 1913, and since 1921 a remarkable increase has been observable in North Africa. In Algeria the output has risen from 400,000 t. in 1921 to over 620,000 t., in Tunis from 1,418,000 t. to 2,500,000 t., and in Morocco from 80,000 t. in 1922 to over 250,000 t. at present. This increase is in sharp contrast with the decrease in the world's production of crude phosphates. An interesting tendency is to use finely ground mineral phosphates direct as an agricultural fertiliser, also the use of crude phosphates that have been calcined in rotary furnaces. The major part of the mineral phosphates, however, is converted into superphosphates, an industry which is developing owing to the large production of sulphuric acid, the French output having increased from 1,920,000 t. in 1913 to roughly 2,500,000 t., with exports approximating to 130,000 t. The consumption of superphosphates increases annually in France. French agriculture pays more attention to the use of basic slag, the by-product of the steel industry, and of which the production may attain, at normal rate of working, 2,000,000 t., though at present it is not greater than 1,000,000 t., and the consumption of 400,000 t. allows heavy exports.

The return of the Alsatian potash mines has made France an exporter of potash salts. The annual production is roughly 1,080,000 tons of salts (250,000 t. K_2O), and the exports are about 7000 t. of potash salts yearly. An agreement has been reached between the French and German producers of potash salts, and the French producers are seeking a market in Austria. The production can be raised to 500,000 t. K_2O per annum, and the construction of new shafts is being considered. In the nitrogen industry, the recent law approving the installation of the Haber process at Toulouse and the constitution of an Office Industrielle de L'Azote foreshadows an interesting increase in the French production of nitrogen. Under modern agricultural conditions, French agriculture would require at least 300,000 t. of nitrogen, whereas the production only reaches 19,000 t., in addition to imports of 70,000 t. The production of ammonium sulphate is 88,500 t. and imports are 75,000 t. The chief occurrences of note during the year are the starting-up of plants erected by the large chemical manufacturers utilising the Claude, Casale and other processes. The imports are thus likely to be reduced by the development of these processes, and of the production of by-product ammonium sulphate and of cyanamide (50,000 t. annually). Imports of Chilean nitrate are still roughly 270,000 t., imports of Norwegian nitrate of lime being 11,000 t., and of cyanamide, 12,000 t. The use of the hydrogen from coke-oven gases in the Claude and Casale processes suggests the possibility of synthesising ethyl alcohol from the ethylene of coke-oven gas. With the Claude and Casale processes and the manufacture of cyanamide, plants now constructed or about to be constructed will fix 69,000 t. of nitrogen in a few years. The utilisation of 600,000 t. of fixed nitrogen in agriculture is a decided possibility of the future.

The manufacture of dyestuffs has increased from the production of 1000 t. in 1913 to 10,000 t. at present, and imports of 6000 t. in 1920 have been reduced to 1000 t. Taking account of the exports, it will be noticed that in ten years, of which only five were really effective, the French Industry has greatly reduced imports and has increased its production from 10 per cent. to 90 per cent. Thus, imports of azo dyes have been reduced from 47 to 8 per cent. The production of indigo is sufficiently large to allow exportation, but small quantities of sulphur dyes have still to be imported. Progress has continued to be made in the other groups of dyestuffs. New plants manufacture the larger part of the undermentioned products and also supply the perfumery and pharmaceutical industries.

In the fuel and petroleum industry the chief event has been the encouragement to exploration in France and its colonies and the search for substitutes for petroleum such as alcohol, gas oil, benzole, "Carburant National," tetralin, wood charcoal, and various kinds of vegetable, animal, and shale oils. The output from the single French oilfield at Pechelbronn is of the order of 75,000 t. of crude oil yearly and is being increased.

Compared with the pre-war figures the production of dyeing and tanning extracts has diminished, but the manufacture of chestnut extract (80,000 t. per annum), and of oak extract, are prosperous. Exports of dye-woods amount to some 3000 t. The glue and gelatin industry had a prosperous year during 1924 and exported 4000 t. In the industry of artificial plastics and artificial textiles, the manufacture of cellulose acetate and of synthetic resins such as bakelite is developing. During 1923, 30 t. of synthetic resin was manufactured monthly and 17 t. was imported monthly from Germany. In 1924, the output was 50 t. monthly, and as the increase of customs duty in November, 1924, practically prohibited importation, manufacture will further develop. It is estimated that some 60 t. of cellulose acetate is made monthly and production is expected to increase still further now that a further factory has been established. During the year the increasing demand for artificial silk led to the establishment of a large number of factories using either the acetate, viscose or Chardonnet processes. Difficulties in the dyeing of cellulose acetate silk have now been overcome.

MODERN ELECTROLYTIC CELLS

By PROF. A. J. HALE, B.Sc.

(Concluded)

CELLS FOR PRODUCING VARIOUS COMPOUNDS

The most important of these cells are those used for the production of hypochlorite liquors and chlorate. Considerable progress has been made during recent years with hypochlorite electrolysers, the early type of Kellner and Oettel being followed by improved cells such as those now being constructed by Mather and Platt of Manchester, and the "Manchester" Electrolysers made by F. S. White and Company of Prestwich.

Platinum electrodes have been superseded by graphite, each cell carrying a considerable number of bi-polar electrodes. Circulation of the electrolyte coupled with efficient cooling is essential for the production of hypochlorite from brine. One electrolyser (Fig. 32) consists of a rectangular trough of glazed earthenware divided into a number of cells by graphite plates which act as electrodes. the graphite electrodes are not suspended, but rest on a glass bottom cemented into the trough. In this electrolyser 1 kg. of active chlorine is obtained by the expenditure of 8 kw.-hrs.

The "Manchester" electrolyser (Fig. 33) consists of a rectangular stoneware trough divided by carbon plates into some 30 compartments, each chamber having a hole at the bottom and another at the side about two inches from the top. The electrolyser is placed in a tank, 6ft. by 4 ft. by 3 ft. deep and this is filled with 15 per cent. brine. When electrolysis starts the evolution of hydrogen carries the liquid upward causing it to overflow through the openings in the sides, whilst it is replaced by fresh brine entering through the holes in the bottom. Each electrolyser takes 80 amperes at 110 volts and lead coils through which cold water circulates are placed on each side to keep the temperature below 30° C. A consumption of 88 kw.-hrs. yields about 10 kg. of active chlorine. In some electrolysers only 6—7 kw.-hrs. are required to give 1 kg. of active chlorine, the average concentration being 10—15 grams per litre.

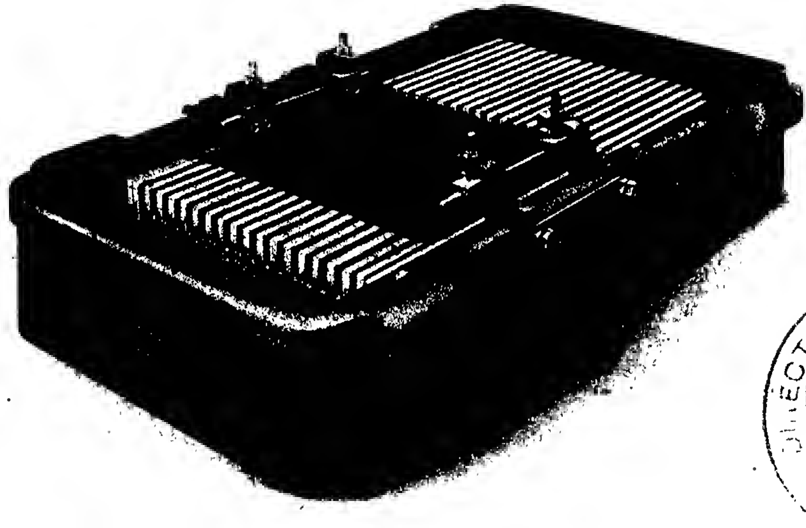

FIG. 32
The Mather and Platt Electrolyser

The channels between these plates are continued at either end by walls formed of glass plates. A chamber at one end receives the electrolyte from the pump, and the liquid flows over a glass weir into the spaces between the electrodes, thence into a second chamber from which it is again passed to the pump and recirculated until the brine contains about 12 grams of active chlorine per litre. The tank beneath the electrolyser is fitted with cooling coils to keep the electrolyte at a low temperature, 20—30° C. There are 17 cells in the trough illustrated and a voltage of 100/110 volts is required at the terminals for the passage of the normal current of 80/100 amperes. The glass plates and

In the "platinode" electrolyser, made by Mather and Platt, Ltd., an ebonite cell (Fig. 34) is fitted with platinum electrodes which are built into the body of the cell to afford them protection from injury. This cell is placed in a glass container and any number of these containers may be placed in a cooling trough. Each glass cell is filled with 20 per cent. brine and requires 5 amperes at 10/12 volts when working. The 1200 c.c. of liquid in the container will be brought to a content of 20 grams available chlorine per litre in approximately $4\frac{1}{2}$ hours.

The internal structure of the unit is shown in Fig. 35. The platinum foil electrode, *a*, is backed with a vulcanite block, *b*, and inserted in a dished

recess in an ebonite plate, *c*. The foil is connected with a terminal, *f*, by a platinum wire, *e*, in the channel, *d*. The electrode carrier shown is normally immersed in the electrolyte to the depth indicated by the horizontal line and access of the electrolyte to the channel, *d*, is prevented by a filling squeezed into position by the plug, *h*. Electrolyte circulates by the opening, *j*, at the bottom of the cell through the channel, *i*, and overflows through openings in the side on the electrolyte level.

In the press type electrolyser of Mather and Platt (Fig. 36) there are 23 graphite electrodes forming 22 cells, mounted transversely on steel bars covered

the required amount of active chlorine, 11—12 grams per litre, has been formed.

This type of electrolyser requires 225 to 250 amperes at 100—110 volts and will give 9 lb. of active chlorine per hour, the power consumption being relatively low, 3 kw.-hrs. per lb. of active chlorine, that is about 6 kw.-hrs. per kg. The electrolyte is allowed to circulate through at the rate of 18 gallons per minute.

Another hypochlorite electrolyser made in various sizes is the "Graphode" (Mather and Platt) a 5-ampere unit being shown in Fig. 37. It consists of a stout holder with graphite electrodes forming five cells, the

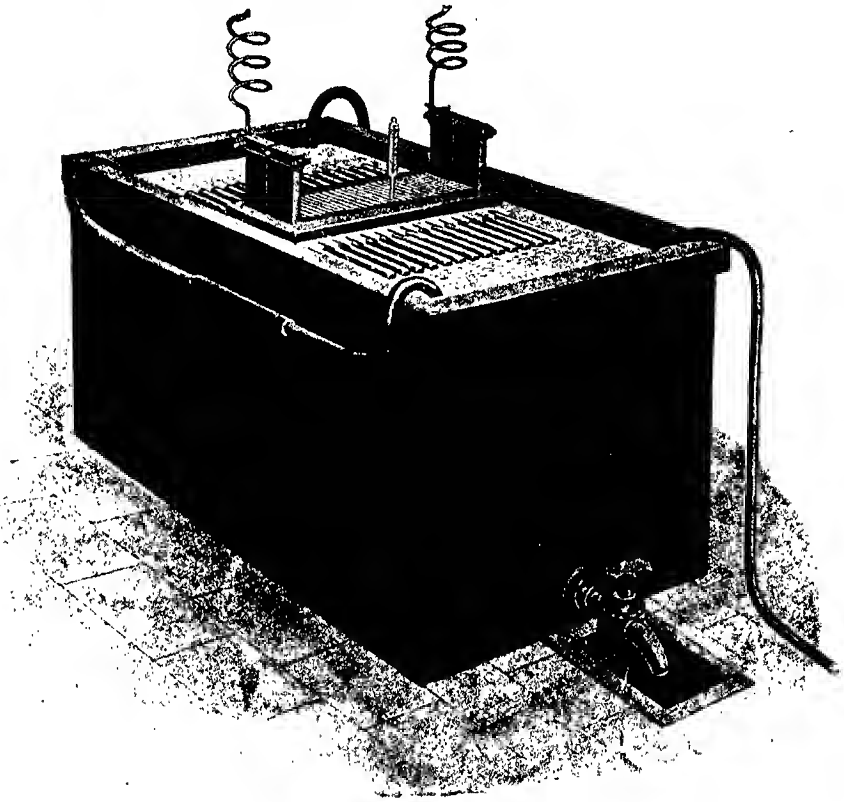

FIG. 33
"Manchester" Electrolyser by F. S. White and Co.

with vulcanised rubber. The cells are formed by suitable insulating distance frames between the electrodes, end pressure screws being provided for adjusting purposes.

Brine liquor falls into the electrolysers through the perforated bottom of a cast iron feed tank which is lined with vulcanite, and each cell is fitted with an outflow syphon-tube which regulates the flow and ensures that each cell is filled to the required height. The electrolysed liquor falls into a cement trough from which it is pumped to the cast iron feed tank, the circulation being continued until

whole being placed in a glass container of about 1 gallon capacity. After about 3 hours a concentration of 10 grams of active chlorine per litre will be reached with a voltage of 20—24 volts. Units of larger capacity (12½ or 30 amperes) can be supplied, but they are usually equipped with sufficient graphite bi-polar electrodes to render them serviceable with the ordinary electricity supply.

Chlorate and perchlorate cells, especially the former, are generally constructed on a larger scale, and the graphite anodes are connected to a common bus bar, the iron tank itself often being the cathode.

The chlorate cell of the United Alkali Company (E.P. 173,028/21) is an iron tank, 8 ft. x 4 ft. x 15 in. wide, and is fitted with a central steel cooling coil. Both the coil and the tank serve as cathodes whilst ranged around the tank are graphite anode --ds at which chlorate formation takes place when

Fig. 34
"Platinode" Electrolyser

he potassium chloride solution is electrolysed. The emperature being maintained below 40° C., the arbon anodes are not seriously corroded by the hlorate. A current of 1500 amperes may be used, ployed are of the diaphragm type, as it is necessary to prevent cathodic hydrogen from interfering with the discharge reaction taking place on the anodes.

Hydrogen peroxide is frequently produced by the distillation of acidified ammonium persulphate, this salt being always manufactured by electrolysis of ammonium bisulphate solution.

The simplest form of cell from which the larger industrial units are planned consists of an outer earthenware jar in which stands a porous pot. Any kind of cylindrical electrode suitable for the work to

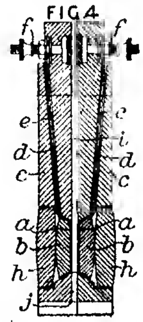

Fig. 35
"Platinode" Electrolyser

be done can be used, one for the inside of the porous pot and a larger one outside it, and all electrolytic oxidation or reduction can be accomplished on the laboratory scale in such apparatus. Sodium hydrosulphite is the principal salt prepared by electrolytic reduction, but a diaphragm is not essential for this purpose. If a suitable solution of bisulphite is allowed to circulate through an electrolytic tank or cell at

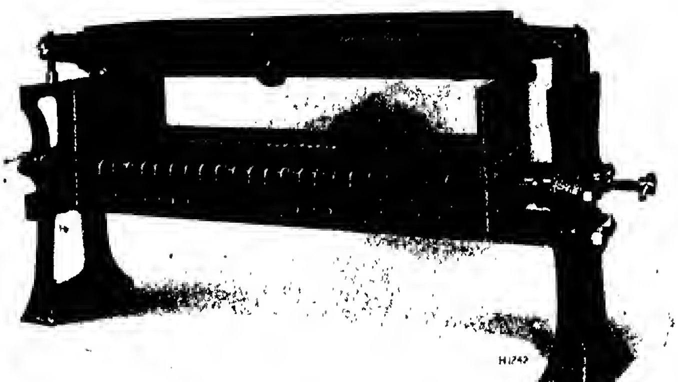

Fig. 36
Vertical Flow Type of the Mather and Platt Electrolyser

nd the electrolyte is caused to circulate in the tank r, when a number of tanks are in use, a cascade ystem of circulation can be utilised.

Persulphates, permanganates and perborates can e manufactured by electrolysis. The cells em- 10–15°, concentrated solutions of hydrosulphite can be obtained (E.P. 13,901/13).

For reduction or oxidation of organic compounds, the most promising field in which electrolysis as applied to organic compounds is being explored, the

simple cell described above suffices, although it may be often necessary to fit such cells with a gas-tight cover, refluxing apparatus and a good stirrer in order to obtain satisfactory results.

Recent patents of C. J. Thatcher for a diaphragm cell, in which organic substances can be oxidised or reduced (E.P. 188,056/22), and for a series arrangement of diaphragm cells in which anthracene may be converted into anthraquinone (E.P. 188,042/22) indicate some advance in this field.

The Society of Chemical Industry in Basle some years ago devised a tank cell, for organic reduction or oxidation, in which the electrodes are fixed horizontally, one near the surface of the electrolyte, and the other near the bottom. The compound to be treated is dissolved in a light or heavy solvent which easily forms an emulsion with the electrolyte (caustic soda or dilute sulphuric acid) such emulsification being assisted by a to and fro motion of the electrode concerned in the reaction (E.P. 15,750/15). This cell is now in use on a large scale.

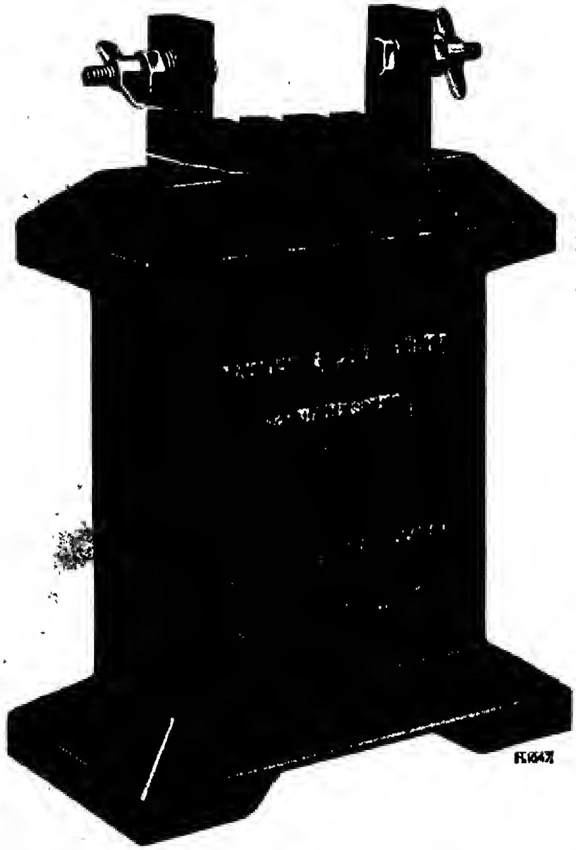

FIG. 37
"Graphode" Electrolyser

Recently Plauson has patented a cell for chlorinating, oxidising or reducing by electrolysis (E.P. 181,848–49/21). It resembles the common cylindrical diaphragm cell in many respects, but one electrode, which is centrally placed within the porous pot or diaphragm, is formed of a metal tube fixed in a porcelain insulator so that only a very small portion of it is exposed to the electrolyte. In this manner a very high current density is obtained, so that the electrode may be maintained at any temperature up to about 120°, and in this condition, promotes many electrolytic changes which, under ordinary conditions, take place to only a small extent or not at all.

Cells constructed on the plan of the cylindrical diaphragm unit for producing caustic soda will, no doubt, prove suitable for the reduction or oxidation of organic compounds, the central compartment containing the organic substance to be treated. The diaphragm, however, must be protected by some non-conducting material such as vulcanite, from the excessive wear which will result from vigorous stirring of a solution or emulsion of the compound to be reduced or oxidised.

The electrolytic cells described in this article represent the various types which have been designed for electro-chemical service during the last twenty-five years. From a study of their construction it should be possible for an investigator in this field to devise a cell suitable for the special electrolytic process which it may be his object to develop.

[Acknowledgment is due to the various firms who have kindly supplied illustrations and information, and particularly to Messrs. Longmans, Green and Co., for permitting the reproduction and lending the blocks of Figs. 16, 17, 18, 21 and 27 (from the author's "Applications of Electrolysis in Chemical Industry") and to Messrs. Virtue and Co., Ltd., for a similar favour in respect of Figs. 1, 3, 5 and 20, which are from the author's "Modern Chemistry, Pure and Applied.—ED.]

THE PROPERTIES OF SOME ALIPHATIC COMPOUNDS CONTAINING BOTH OXYGEN AND NITROGEN, AND THEIR CONNEXION WITH THEORIES OF LATENT POLARITIES AND AROMATIC SUBSTITUTION

By PROF. ARTHUR LAPWORTH, D.Sc., F.R.S.

In a paper on "Latent polarities of atoms, etc" (*Mem. Manch. Lit. and Phil. Soc.*, 1920, 64, ii., 1 *et seq.*) the generality of "the principle of induced alternate polarities" was shown, by considering reactions of molecules containing either one predominating "key atom" or two effective "key atoms" arranged "homogeneously"—that is to say, in such positions as would lead to the same relative latent polarities in the atoms affected by both.

The much more abstruse question of effects resulting from "heterogeneous" arrangements of two or more powerful "key atoms" was not dealt with in detail, but a preference was expressed for the idea that the molecule might at different times be activated

from different "key atoms," and thus occur in two (or more) phases with inverted relative induced latent polarities (*loc. cit.*, p. 6, (A) and (B) as examples). No case was mentioned where two atoms, each capable of exercising a powerful inducing effect, are so arranged that an effect from one must necessarily be transmitted "through" the other. Had it been he writer's intention to enter into such complex uestions he would have selected the cases of oxygen d nitrogen competing in this manner, and would ave based his remarks on well-established experi- nental data obtained prior to 1920, and on lines such as the following :—

The first example is familiar to all organic chemists —an oxime. Here, as elsewhere, the most satisfactory test of a marked latent polarity distinction is one based on its reversible reactions with water. The result is unequivocal and shows that the nitrogen atom is negative with respect to the attached carbon atom :—

$$HO{\cdot}N{=}CR_1R_2 + H_2O \longleftrightarrow HO{\cdot}NH_2 + O : CR_1R_2$$

he same conclusion follows from the reversible dition of hydrogen cyanide at the same position :—

$$HO{\cdot}N{=}CR_1R_2 + H^{\cdot} + CN' \longleftrightarrow HO{\cdot}NH{\cdot}C(CN)R_1R_2$$

oth this and the previous reaction occurring exclu- ely in the direction indicated.

In the case of nitroso compounds on the other and, the balance between the nitrogen atom nd the oxygen atom appears to be in favour of he oxygen atom in all cases in which this can be ested by the behaviour of the compound in eactions with ionisable compounds $\overset{-}{X} - \overset{+}{Y}$, or 1 reactions giving rise to such an ionisable com- ound. The balance between the nitrogen atom and e oxygen atom is, however, so extremely easily sturbed that in nearly all cases where the change is ssible, the compound undergoes isomerisation into oxime in which the nitrogen atom definitely exer- es full control over the system which it separates, gr aphically, from the oxygen atom.

Co sidering next the normal nitroparaffins. These mp ounds show properties which are in excellent cord with the assumption that the oxygen atoms termine the order of polarities, even "through" e intervening nitrogen atom. In the *iso*-nitro- raffins the predominance of the oxygen atoms evident only in so far as these compounds show tendency to revert to the normal nitro-compounds- r the rest it is known that, in some cases at least, e major portion of the *iso*-nitro-compound undergoes drolysis when liberated from its salts, the hydro- sis doubtless taking place in much the same way with oximes, but in the case of the oxy-oximes, *iso*-nitro-paraffins, the oxyhydroxylamine (dehy- oxylamine) formed appears, as usual, in the form nitrous oxide, the organic residue turning up as lehyde or ketone (compare Nef, *Annalen*, 1894, 0, 263, and Lowry, *Trans. Chem. Soc.*, 1898, , 992) :—

$$HO_2\dot{\bar{N}}{=}\overset{+}{C}R_1R_2 + \overset{+}{H_2}\overset{-}{O} \rightarrow [H_3NO_2] + O{:}CR_1R_2$$
$$\downarrow$$
$$\tfrac{1}{2}[3H_2O + N_2O]$$

[t seems clear, therefore, that in the same compound w one atom and now another may assume the rôle of "key atom." It should also be evident that no organic chemist worthy of the name would at any time, since oximes became familiar, have suggested that divalent oxygen must necessarily be the dominant atom in molecules also containing nitrogen.

In considering these facts and their bearing on aromatic substitution, it has to be remembered that divalent oxygen and tervalent nitrogen directly attached to the nucleus exercise a very great *o-p*-directive effect. When either atom is separated from the nucleus by an intervening atom, however, its influence is exceedingly small (for example, substitution in salicylic acid is almost wholly determined by the oxygen atom directly attached to the nucleus). If, therefore, in nitrosobenzene, for example, the "key negative" influence of the nitrogen atom is not wholly suppressed by its association with the oxygen atom, any influence of this kind will be grossly exaggerated during the process of activation of and substitution in the nucleus, just as any polar properties of the oxygens of the carboxyl group in salicylic acid are ineffective as compared with the polar properties of the phenolic oxygen.

SOCIETY OF CHEMICAL INDUSTRY

MEETING OF COUNCIL

The monthly meeting of Council was held on December 12, 1924. The President (Mr. W. J. U. Woolcock, C.B.E.) was in the chair.

The President extended a cordial welcome to Mr. G. H. Clegg, and Prof. N. M. Comber, new members present for the first time.

The following among other matters were dealt with:

The Address to be presented to the University of Leeds on the occasion of the celebration of its coming of age was submitted and approved.

The steps taken at headquarters and by the local sections to obtain new members were reported. The effect of the entrance fee being suspended for 1925 had been widely advertised, and a notable increase in the number of applications had already resulted, at the same time, the numbers of resignations and of unpaid subscriptions for the current year were distinctly less than the numbers at the corresponding date in 1923.

Reports of various sub-committees were submitted, and 48 new members were elected: Home 37: Overseas 11.

The question of a member bringing more than one guest to the Annual General Meeting and having to be supplied with tickets for all the functions, for many of which no payment is made, was fully discussed, and it was decided that every member of the Society attending the Annual Meeting has a right to obtain a ticket for one guest, and has also the privilege of obtaining further tickets by payment of 10s. 6d. in respect of each additional guest.

SUSPENSION OF ENTRANCE FEE

As an inducement to Chemists to become members, the Council has resolved that no entrance fee shall be paid by members joining the Society in 1925.

A form of application for membership was inserted at the end of this Section in the issue of the Journal for October 17, and it is hoped that it may be used to introduce a new member for next year.

BACK NUMBERS OF JOURNAL

The General Secretary will be glad to hear from Members or Subscribers who have copies of the *Journal* for January 4, June 13 and 27, July 4 and 25, September 19, or October 3 and 17, 1924, that they are willing to dispose of to the Society.

EDINBURGH SECTION

The third ordinary meeting for the present session was held jointly with the Institute of Chemistry, in the Hall of the Pharmaceutical Society, 36, York Place, Edinburgh, on December 11, 1924, Dr. A. Lauder in the chair.

Lieut.-Colonel W. Glen-Liston, C.I.E., M.D., delivered a lecture on "Fumigation with Hydrogen Cyanide." The first use of hydrogen cyanide had been made by James Bell, who in 1877 employed it to prevent the destruction of his collection of insects by moths and other vermin. In 1886 Coquellet had introduced the gas for destroying parasites on citrus trees in California. So successful had the method proved that by 1890 it was in general use throughout the district. The next development had been made by the Cape Government in 1898, when hydrogen cyanide was employed for fumigating railway carriages. From then on its use had grown steadily, and experiments for the destruction of rats in the East had been started in 1909. These experiments had been undertaken for the purpose of reducing the ravages of plague, which it had been proved had been distributed by fleas with which rats were infested. In connexion with the fumigation of ships, the method had grown extensively, so that in 1922 no less than 1347 vessels had been disinfected with hydrogen cyanide in New York Harbour. Owing to the deadly nature of the gas great care had to be taken in clearing any closed space which had been fumigated. The apparatus designed by Lieut.-Colonel Glen Liston to facilitate the use of the gas was exhibited and explained by means of lantern slides, and an account was given of experiments which had been made on various ships with the plant.

CHEMICAL SOCIETY

An ordinary scientific meeting was held on Thursday, December 18, when the President announced that no award of the Harrison Prize could be made this year; a serious difficulty in making any award had, in fact, arisen in connexion with the interpretation of the trust deed.

The first paper was read by Mr. D. A. Spencer:—

The action of bromine on sodium and silver azides. Parts I and II.

In the absence of water, bromine reacts with sodium and silver azides to give the highly unstable triazobromide:—

$$XN_3 + Br_2 = XBr + N_3Br$$

This compound, whilst resembling triazoiodide in its general properties, differs in its greater volatility and immediate decomposition by water.

Bromine water reacts instantly with sodium azide solutions to give a mixture of azoimide and hypobromous acid. The solution then evolves nitrogen as a result of the interaction of these substances

$$NaN_3 + Br_2 + H_2O = NaBr + HN_3 + HBrO$$

The reaction between silver azide and bromine water differs from that with iodine solutions in that it is better represented:—

$$2\ AgN_3 + Br_2 = 2\ AgBr + 3\ N_2$$

The only evidence for the momentary existence of triazobromide in aqueous solution is the formation of a certain amount of azoimide with consequent loss of free nitrogen.

The density or viscosity of all nitrogen samples obtained was determined, but no indication of the existence of the polymer N_3 was obtained.

Dr. R. H. Pickard, congratulating the author on overcoming the experimental difficulties attendant on the explosive nature of the substances investigated,

said that he was glad to hear that work of this character was being carried out in an English laboratory. The results seemed to demonstrate the existence at low temperatures of the compound N_3Br.

The President also referred in appreciative terms to the author's courage and good luck.

Mr. W. H. Patterson then read the following paper :—

A method of determining the presence or absence of complex salts or ions in dilute aqueous solutions. [With J. Duckett.]

The method described is the change in the critical solution temperature of phenol and water by the addition of salts or salt mixtures. The complexity of the salts is thus tested in dilute aqueous solution above 66° C. The investigation might be extended, however, by selecting other temperatures of mutual miscibility and also for other solvents.

It has been shown (in a previous communication) that the ions may be arranged in a series, nearly identical with the Hofmeister series, and thus the effect of any simple salt (essentially soluble in water only) in raising the critical solution temperature may be foretold.

If, *e.g.*, 0·1 mol. of one salt and 0·1 mol. of another salt (per 1000 gms. of total solution) are added to the phenol water mixture, and no complex occurs, the critical solution temperature found is the mean for 0·2 mol. of each salt separately. If a complex is formed in solution there is a change in condition and temperature.

Simple mixture was found in the case of the following :—

NaCl, KCl : KCl, LiCl.
$MgSO_4$, K_2SO_4 (schoenite)
$MgSO_4$, Na_2SO_4 (astrakanite)
Alums
$MgSO_4$, KCl (kainite).

Complex formation :—

HgI_2,KI
CdI_2, KI.
Sodium ferrioxalate
Sodium ferrocyanide.

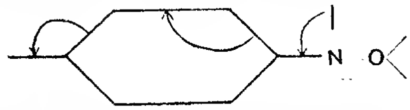
In reply to Prof. Bassett, Mr. Patterson said that the advantage of his method over other recognised methods lay in its greater delicacy and ease of application, and in the fact that the question of the influence of the solvent did not arise.

Prof. C. K. Ingold next discussed :—

The nature of the alternating effect in carbon chains. Part I. The directing influence of the nitroso-group in aromatic substitution.

The directing influence of the nitroso-group in aromatic substitution has been determined—for chlorination, bromination and nitration—and the results are better in harmony with the view that the alternation along a carbon chain is an alternation in the quantity, rather than in the electropolar quality, of the residual affinity.

A letter from Prof. R. Robinson, in the following terms, was read by the Secretary :—" The directive effect of the nitroso-group ought to be *o-p* because like the azo-group and one end of the azoxy-group it is a group which can increase its covalency with the nuclear carbon with the aid of free electrons (lone pairs) in the octet of the nitrogen atom nearest to the nucleus. Aromatic substitution in the course of nitration, halogenation, sulphonation, or coupling with diazonium salts depends on a reaction cycle in the performance of which the carbon atom in the position attacked becomes negatively charged. By virtue of the tendency for a more even distribution of valency (actual, not residual) such negative charge is very easily acquired in the *p*-position to any atom attached to the nucleus and containing lone pairs in its octet. Representing an electron pair by a line, the following exhibits the covalency changes leading to the negatively charged *p*-position :



This figure is in strict accordance with the views on the electronic explanation of conjugation which were expressed by Kermack and Robinson. It is also in agreement with Prof. Lapworth's views. According to this hypothesis only one positively and one negatively charged centre exists in any particular activated phase. Symbols such as $\overset{-}{A}-\overset{+}{B}-\overset{-}{C}-\overset{+}{D}$, etc., merely express what may happen in a number of conceivable activations of the molecule. Polar activation and valency redistribution occur simultaneously and are not, as Prof. Ingold seems to imply, irreconcilable hypotheses."

Prof. G. T. Morgan, recalling the days when he had received instruction in the Crum Brown rule from the President, remarked that the rule, although showing how substitution occurred, did not explain why it did so. Nevertheless, subsequent experimental work remained in consonance with the rule, except in the case of nitration of aromatic amines. Here, however, a derivative, and not the base itself, was usually concerned, and variation in the course of nitration according as the sulphuric or nitric acid is present in excess was usually accounted for by postulating the formation of an intermediate derivative. The speaker, while disclaiming any knowledge of " this plus and minus business," was, on the whole, rather inclined to prefer Flürscheim's theory.

Dr. B. Flürscheim remarked that substitution in the benzene ring was the simplest case for experimental investigation, which would assist in the elucidation of the whole question of chemical affinity. Whilst many experiments were necessary to prove a theory, only one was necessary to destroy it! He was unwilling to deal at such short notice with Prof. Robinson's contribution, but amid some amusement he admitted his impression that the latter author was " trying to make on the swings what he had lost on the roundabouts." Prof. Ingold's results, he said, could also be explained by Thiele's Partial Valency Theory, but that would similarly postulate *o-p*-orientation for every other substituent containing a double bond directly attached to the benzene nucleus, a postulation which was

contrary to fact. The results militated not only against the induced polarity theory of aromatic substitution, but also against any electronic aromatic substitution theory so far advanced, since the proved increase of electron affinity in proceeding from left to right of a period in the periodic classification necessitated that in —N=O, oxygen should be given the negative and nitrogen the positive sign, if signs were to be used at all.

Prof. Ingold said that his paper was primarily intended to publish a new experimental fact; he found great difficulty in understanding the views expressed by Prof. Robinson. The issue could only be settled by crucial experiments in some dozens of suitable cases.

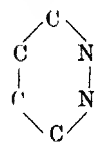
The President, in according the author the thanks of the meeting, said that Prof. Lapworth had expressed great regret at his enforced absence.

Prof. Ingold then dealt with the substance of the following three papers:—

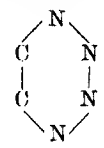
The additive formation of four-membered rings. Part VI. The addition of azo-compounds to ethylenes and some transformations of the dimethylene-1 : 2-di-imine ring. [With S. D. Weaver.]

EXPERIMENTS on the additions of azo-compounds to ethylenes have resulted in the production of four and six-membered rings of the types I, II, and III. Some transformations of these, including the production of a hetrocyclic bridged-ring are also described.

I



II



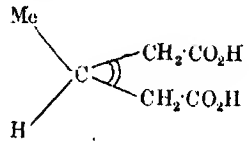
III

The chemistry of the glutaconic acids. Part XVII. Three-carbon tautomerism in the cyclopropane series. Part IV. [With F. R. Goss and J. F. Thorpe.]

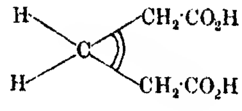
A NOTEWORTHY characteristic of glutaconic isomerism is that it can co-exist with tautomeric mobility, which, presumably, would destroy any definite geometrical configuration around the double linking. It is shown that this characteristic reappears in the cyclic series, and new proofs are given (1) of the mobility of the three-carbon system; (2) of the absence of ordinary structural isomerism (*cf.* Feist, *Annalen*, 1924, **436**, 135). (Geometrical isomerism is necessarily absent for stereochemical reasons.) It is also shown that both series of isomerides can display optical activity, an observation which is being followed up since it forms an important check on all speculations regarding the nature of the isomerism.

The conditions underlying the formation of unsaturated and cyclic compounds from halogenated open-chain derivatives. Part VI. Products derived from halogenated a-methylglutaric acids.

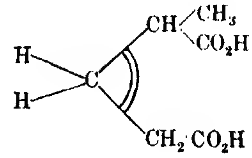
THE correctness of the theory connecting the angles between carbon-to-carbon valencies and the atomic volumes of the attached groups is confirmed by the correspondence between the anticipated order in a series of substances and the observed order in relation to ease of ring formation. Thus in glutaric acid (II) the replacement of one of the β-hydrogen atoms by methyl would depress the angle between the acetic acid chains (I); on the other hand, the replacement of one of the α-hydrogen atoms by methyl would increase the angle because of the greater space-filling power of the branched acetic acid chain (III).



II



I



III

These conclusions have been tested by the method used in previous investigations of the series, and the results have been found to be in good agreement.

Prof. D. R. Boyd, congratulating the authors, asked whether they were convinced that in the case of the *cyclo*propene acid stereoisomerism of the deflection type was impossible.

Dr. J. L. Simonsen briefly contributed to the discussion.

Dr. F. R. Goss replied. Whilst admitting that the suggestion of an abnormal deflection of the valency linking the methyl group might serve as an explanation of the isomerism of the cyclic acid, he did not think that such a suggestion could be given weight in view of the fact that it could not be applied to the similar isomerism throughout the glutaconic series.

In view of the lateness of the hour, the reading of a paper on 6-chlorophenoxarsine by Dr. E. E. Turner and Mr. A. B. Sheppard was postponed.

THE SUGAR REFINING INDUSTRY AND THE BEET SUBSIDY

According to *The Times* it appears that the sugar-refining industry is in a serious position and considers that the Government subsidy should be confined to raw beet-sugar and not extended to its refining by the three groups engaged in the development of beet-growing. With a combined capacity for refining 1,500,000 tons of sugar annually, the industry produced only 1,100,000 t. last year, the decrease being ascribed to foreign competition. One firm of refiners, however, held more optimistic views of the future, believing that prices were near bedrock, so that a better position could be anticipated; especially as there was always a steady demand for British-refined sugar, owing to its superior quality and consistency.

CORRESPONDENCE

PERFUMES FROM SCENTLESS FLOWERS

Sir,—Great as have been the achievements of the rticulturalist in the evolution of improved fruits id blossoms, little attention seems to have been paid therto to the question of the production of perfume r the hybridisation of scentless flowers. The modi- ations of fruit and blossom probably proceed in cordance with the hypotheses advanced by Lamarck id Darwin, but the production of perfume, where one previously existed, is a problem appropriate to e technical chemist. It is noteworthy that the alian professor, Guido Mariotti, has been able by ybridisation to produce, not only a scented camelia, it also some thirteen varieties of coloured and ented gardinias shaped like roses. It may be noted so that the deliciously scented sweet pea of to-day omes from a scented stock. Perhaps it is pertinent remark that scented fruits like the pear and the pple are the product of an odourless blossom; rther, that many flowers are odoriferous at certain nes of the day, but scentless at others. This whole bject, that of the production of pleasant smelling ganic compounds by suitable plant breeding, is its infancy. It is, perhaps, not extravagant to iggest that it may develop into a very important ranch of chemical technology.—I am, Sir, etc.,

Margate F. DE FABRETTI

PERSONAL AND OTHER ITEMS

Mr. D. C. Henry, M.A., has been elected a member f the Board of the Faculty of Science in the Man- hester University.

The degree of D.Sc. of the University of London as been conferred on Mr. Harold Hunter, of East ondon College and Battersea Polytechnic.

Mr. A. F. Greaves-Walker, head of the ceramics epartment of the North Carolina State College, as been appointed consulting refractories engineer or the United States Bureau of Mines.

The honorary degree of D.Sc. was conferred on meritus Prof. J. B. Cohen, F.R.S., during the elebrations of the coming-of-age of the University t Leeds. The honorary degree of LL.D. was con- erred on M. J. Louden, chairman of the Textile ndustries and Dyeing Committee of the University.

William Alexander Smith, of Tay Bank, Helens, urgh, N.B., chairman of Messrs. Bryant and May- td., a director of the Bakau Co., Ltd., the British hemical Co., Ltd., the Scottish Acid and Alkali o., Ltd., and chairman of the Carpet Manu- acturing Co., Kidderminster, who died on August 5, aged 77, left personal property of the value of 35,217.

The name of Herman Frasch is well known to hemists, for his discovery of a method for removing bjectionable sulphur from petroleum and par- icularly for his fine chemical engineering work which nade it possible to utilise the deep-seated deposit f sulphur in Louisiana and Texas. The will of his idow, Mrs. E. B. Frasch, now made public, bequeaths several million dollars to found the Herman Frasch Foundation for Chemical Research with the object of encouraging research in agricultural chemistry.

As another illustration of the growing tendency in the United States to apply accumulated wealth for the betterment of the public, it is interesting to record that the late A. W. Preston, President of the United Fruit Co., has left, in default of issue, several million dollars to be used for "advancing the science of chemistry in the United States."

Mr. L. Emery, who died in Philadelphia recently, was a pioneer chemical manufacturer and oil producer in the United States. He will be best remembered as one of the first manufacturers of oxalic acid by the potash and sawdust process and for his staunch fight to obtain a tariff protecting the manufacture against German competition.

The death is announced, from New York, of Dr. E. J. Winter, consulting chemical engineer, who was a well-known expert on industrial distillation.

Harrison Memorial Prize

The Harrison Memorial Prize Selection Committee is unable to make an award of the Harrison Memorial Prize for 1924.

A New Insecticide

Research on various insecticides has shown that sodium fluosilicate can be used to replace arsenicals and sodium fluoride in the control of various insect pests. Sodium fluosilicate is cheaper, acts as a contact as well as a stomach poison, kills more rapidly, is not so poisonous to people and is effective against a wide range of insects. The disadvantage of commercial sodium fluosilicate is its density, but it is hoped (*J. Ind. and Eng. Chem.*, Dec., 1924) that with further research a sodium fluosilicate suitable for dusting to control the boll weevil will be ob- tained.

Academie d'Agriculture

M. E. Roux described recent work by M. F. Picard, on the extraction of tannins. Acetone, in which all the tannins are soluble, cannot extract the whole of the tannins in vegetable tissues, boiling water or steam being used for industrial extraction. Extrac- tion, however, is not complete, and a large quantity of tannin is lost. According to M. Picard this loss could be avoided by a double treatment with ether and boiling water, it being possible to recover practi- cally the whole of the ether used for extraction.

Nitrate Producers' Association.

Sales of Chilean nitrate have been resumed by the Producers' Association, an amount of 21,436 metric quintals having been disposed of for delivery in January, 1926. These sales represent the first contracts which had been made since the week ended November 6, when 41,656 metric quintals were sold for shipment in January and February. The total sales of the fertiliser to date for delivery in the current season amount to 18,620,753 metric quintals.

REVIEW

LOW-TEMPERATURE CARBONISATION. By S. N. WELLINGTON and W. R. COOPER. Pp. ix+238. London: Charles Griffin and Co., Ltd., 1924. Price 25s.

The authors present a well-arranged and illustrated account of the more important of the processes proposed for the low-temperature carbonisation of coal. The historical record will prove to be of interest to many, and the chronological treatment of the patent literature in a separate section is to be commended, since the main text is rendered much more readable by its elimination.

To the general reader the section of most interest is that in which the possibility of combining low-temperature carbonisation plant with electrical generating stations is examined in considerable detail. Several alternative proposals are set out and discussed from an economic point of view. The assumptions made will not be accepted *in toto* by anyone. Some of them are startling until it is seen that the authors do not wish to allow bias to influence the figures in favour of raw coal. Perhaps it is sufficient to indicate that the conclusions are very nearly in favour of the consumption of raw coal under boilers at the generating stations in preference to any form of combination of the power plant with the low-temperature carbonisation process. This chapter is of distinct value, since the reader can substitute his own market values for those given and should be assisted in forming considered opinions upon points which are too often the subject of popular discussion without sufficient reference to fact.

The rest of the book is made up of an account of a detailed analysis of a particular low-temperature tar and of notes upon the chemistry of tar and of coal. It is reminiscent of a student's note-book and should have been given more consideration before publication. The abstracts of scientific papers are good in themselves, but an attempt has been made to cover too wide a field, with the result that there is some lack of co-ordination. The reference to the factors affecting the free carbon content of tar is likely to leave quite a wrong impression with the reader, since no hint is given that the free carbon found in ordinary gasworks tar is mainly the result of the decomposition of volatile hydrocarbons at the high temperatures of the retort and is largely influenced by the amount of the free space within the retort.

H. HOLLINGS

PARLIAMENTARY NEWS

British Dyestuffs Corporation

Replying to Mr. Waddington, Sir P. Cunliffe-Lister stated that the question of the financial reorganisation of the British Dyestuffs Corporation had for some time been receiving the attention of the board of the Corporation. They had been informed that the Government were prepared to give favourable consideration to any reasonable scheme with that object in view which may be put forward. In a written answer to Sir W. de Frece, he also said that the Government Directors of the British Dyestuffs Corporation received the same remuneration as the ordinary directors. This also applied to the recently-appointed Government director.—(Dec. 16.)

British Sugar (Subsidy)

In introducing the financial resolution to authorise the payment of a subsidy in respect of every hundredweight of sugar or molasses, Mr. E. Wood said that for refined sugar of a polarisation exceeding 90° the subsidy would be at the rate of 19s. 6d. per cwt. for the first four years, 13s. per cwt. for the three following years, and 6s. 6d. for the final three years, other grades of sugar and molasses being provided with appropriate rates. The policy had been proposed because the experience of all beet-producing countries showed that with this industry it was necessary to be prepared to give a measure of assistance in the earlier years. As a condition of the subsidy it would be necessary for the factory to pay the growers a certain minimum price for the beet which they buy from the farmers during the first four years. That price would be fixed at 44s. a ton with 15½ per cent. sugar content. The second condition was that a factory enjoying the subsidy should use machinery 75 per cent. of which was made in this country. The scale of the subsidy proposed was exactly the same as the scale at present enforced in the Customs Duty, and endeavour had been made to hold the scales evenly between the raw-sugar interest and the refining interest. Some wished to make fine sugar, whereas others, partly because the process was less expensive, and partly because they had no other facilities, wished to stop at the raw-sugar process, and the scale was devised in an endeavour to mete out impartial justice according to a scale, the scientific value of which had been more or less accepted. There was nothing to prevent the refining interest itself going into this business and establishing its own factories and thereby qualifying itself to draw the subsidy. It was proposed to extend slightly the principle by which, if a refiner preferred to go into the raw-sugar process and carry the raw sugar away to his existing refinery, he should receive the sugar subsidy on the refined sugar, on the final stage in the refinery. In conclusion it was stated that the cost of the final resolution would be about £530,000, but off this should be taken about half, which represented the income from the reimposed excise, leaving the net cost to the State about £265,000. The resolution was carried by 223 votes to 22.—(Dec. 18.)

Safeguarding of Industries Act.

Replying to Sir Robert Gower's proposal that owing to the very serious position of the glass-making industry in the United Kingdom on account of unfair foreign competition, glass should be included in any legislation that may be brought in to protect efficient industries, Sir P. Cunliffe-Lister stated that the Government did not intend to schedule any industries in the Safeguarding of Industries Bill. Duties would only be imposed after an enquiry had established that a particular industry fulfilled the necessary conditions.—(Dec. 18).

COMPANY NEWS

COURTAULDS, LTD.

It has been reported that Messrs. Courtaulds have acquired the rights over a new process for the manufacture of artificial silk, by the use of which it is hoped to effect greater economy in production costs and to turn out a much higher-grade material of consistent quality.

A dividend on the 5 per cent. cumulative preference shares will be paid on January 1.

PEACHEY PROCESS CO., LTD.

The annual ordinary general meeting was held on December 17, Sir R. W. Gillan (chairman) presiding. The past year, so far as immediate concrete results were concerned, had been a disappointing one. Very much had depended on the progress of the leather company, since they were the pioneers, and the delay in the development of that company's operations (*cf. Chem. and Ind.*, Dec. 12, 1924, p. 1242) had acted unfavourably on the development of other lines. If this company succeeded, rapid development of business would result, and it was certain that the issue would be settled in a very short time, and their action would have to be made accordingly. The directors proposed, therefore, to call an extra-ordinary general meeting before the end of April next, when the shareholders would be informed of all the facts and of the directors' proposals, and would have an opportunity of discussing them. There had been a large decrease in expenditure, the directors having waived their fees, which had not been drawn for over two years. It was thought inadvisable to weaken control over foreign rights, but it was felt that it would be in the interests of both companies to establish a cordial understanding with the leather company, and for this purpose a joint committee of representatives had been formed.

METROPOLITAN-VICKERS ELECTRICAL CO., LTD.

Mr. Arthur E. Scanes, secretary of the company, will retire at the end of the current year, after being associated with them for 35½ years. Mr. R. H. Haviland has been appointed acting joint secretary as from January 1 next.

SANTA RITA NITRATE CO.

An interim dividend has been declared of 5 per cent., less tax, payable to holders registered on December 18. The dividend for 1923 was 15 per cent., and no interim was paid.

SULPHIDE CORPORATION

The accounts for the year to June 30, 1924, show a net profit of £84,142, to which has been added £100,000 over-provided in former years against taxation, making a total of £184,142. From this has been deducted £183,942 for capital expenditure in excess of amortisation, leaving £200 to be carried forward. In order to combat the fire which broke out in July, 1923, the amount of £187,123 was taken from the reserve for contingencies, reducing that reserve to £92,877.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech. ..	£21 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	.. **£45 per ton.**
Powder.. ..	.. **£47 per ton.**
Acid Hydrochloric	.. 3s. 6d.–6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	.. **£21 10s.—£27 per ton makers' works, according to district and quality.**
Acid Sulphuric ..	.. **Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.**
Ammonia Alkali..	.. **£6 15s. per ton, f.o.r. Special terms for contracts.**
Bleaching Powder	.. **Spot £11 d/d.; Contract £10 d/d. 4 ton lots.**
Bisulphite of Lime	.. **£7 10s.** per ton, packages extra.
Borax, Commercial—	
Crystal.. ..	.. **£25 per ton.**
Powder.. ..	.. **£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)**
Calcium Chloride (Solid)..	£5 12s. 6d. to £5 17s. 6d. per ton, carriage paid.
Copper Sulphate ..	.. **£25 per ton.**
Methylated Spirit 64 o.p.—	
Industrial ..	.. **2s. 7d.—2s. 11d. per gallon, according to quantity.**
Mineralised ..	.. **3s. 8d.—4s. per gallon, according to quantity.**
Nickel Sulphate ..	.. **£38 per ton d/d. Normal business.**
Nickel Ammon. Sulphate	
Potash Caustic ..	.. **£30—£33 per ton.**
Potass. Bichromate	.. **5¾d. per lb.**
Potass. Chlorate..	.. **3d.—4d. per lb.**
Salammoniac ..	.. **£32 per ton d/d.**
Salt Cake.. ..	.. **£3 10s. per ton d/d.**
Soda Caustic, solid	.. **Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.**
Soda Crystals ..	.. £5—£5 5s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	.. **£24 per ton.**
Sod. Bicarbonate (refined)	£10 10s. per ton, carr. paid.
Sod. Bichromate..	.. **4¼d. per lb.**
Sod. Bisulphite Powder 60/62%.. ..	.. **£17—£18 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.**
Sod. Chlorate ..	.. **3d. per lb.**
Sod. Nitrate refd. 96%	.. **£13 5s.—£13 10s. per ton ex Liverpool. Nominal.**
Sod. Sulphide conc. solid 60/65	.. About £15 per ton d/d.
Sod. Sulphide cryst.	.. £9 5s. per ton d/d.
Sod Sulphite, Pea Cryst.	**£15 per ton f.o.r. London, 1-cwt. kegs included.**

RUBBER CHEMICALS

Antimony sulphide—	
Golden	.. **6¼d.—1s. 2d. per lb., according to quality.**

Antimony sulphide—	
Crimson	1s. 4d.—1s. 6d. per lb., according to quality.
Arsenic, Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide	£30—£33 per ton, according to quantity.
Carbon Black	7d.—7½d. per lb. ex wharf.
Carbon Tetrachloride	£60—£65 per ton, according to quantity, drums extra.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes White and Dark	5d.—9¼d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	£48 per ton, barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£16 5s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Precip. B.P.	£50—£65 per ton, according to quantity.
Sulphur Chloride	4d. per lb., carboys extra.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep	5s. 1d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£11 5s. per ton, and upwards.
Grey	£14 10s.—£15 per ton. Firmer.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Demand brisker in many localities.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 9d. per gall. Unrefined.
Wood Naphtha—	
Miscible	4s. 9d. per gall. 60% O.P.
Solvent	5s.—5s. 3d. per gall. 40% O.P. Firmer.
Wood Tar	£4 10s.—£5 10s. per ton. Demand slack and stocks being held.
Brown Sugar of Lead	£42 per ton. Steady market.

TAR PRODUCTS

Acid Carbolic—	
Crystals	5¾d. per lb. Quiet.
Crude 60's	1s. 7d.—1s. 9d. per gall. Market quiet.
Acid Cresylic, 97/99	1s. 11d.—2s. 1d. per gall. Fair business.
Pale 95%	1s. 8d.—1s. 11d. per gall. Not much business.
Dark	1s. 7d.—1s. 9d. per gall. Market dull.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	6½d.—7½d. per gall. Small demand
Unstrained	6d.—6½d. per gall.
Benzole—	Prices advanced; supplies very scarce.
Crude 65's	9d.—11½d. per gall. ex works in tank wagons.
Standard Motor	1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure	1s. 9½d.—1s. 11d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5½d.—1s. 7d. per gall. More inquiry.
Toluole—Pure	1s. 7½d.—1s. 9d. per gall. Steady demand.
Xylol—Coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	8d.—8½d. per gall. Not much business.
Middle Oil / Heavy Oil / Standard Specification	5½d.—6½d. per gall., according to quality and district. Market firmer. Steady demand.
Naphtha—	
Solvent 90/160	1s. 3d.—1s. 6d. per gall. Demand good. Market very firm.
Solvent 90/190	1s.—1s. 1d. per gall. Few inquiries.
Naphthalene Crude—	Cheaper in Yorkshire than Lancashire. Demand rather better.
Drained Creosote Salts	£3—£5 per ton. Steady but quiet.
Whizzed or hot pressed	£6—£9 per ton. No business.
Naphthalene—	
Crystals and Flaked	£12—£15 per ton, according to district.
Pitch, medium soft	50s.—60s. per ton, according to district. Plenty of inquiry for prompt and forward. Market very steady.
Pyridine—90/160	18s. 6d.—19s. per gall. Few inquiries.
Heavy	11s. 6d.—12s. per gall. Rather flat.

INTERMEDIATES AND DYES

Business in dyestuffs has been maintained but without further improvement.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 7d. per lb. naked.
Acid H.	3s. 10d. per lb. 100% basis d/d.
Acid Naphthionic	2s. 2d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid, Salicylic, tech.	1s. 0½d.—1s. 1d. per lb.
Acid Sulphanilic	9d. per lb. 100% basis d/d.
AluminiumChloride,anhyd.	10d. per lb. d/d.
Aniline Oil	8d. per lb. naked at works.
Aniline Salts	8½d. per lb., naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	3s. 10d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 1d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
p-Chlorphenol	4s. 3d. per lb. d/d.
o-Cresol 29/31° C.	3½d.—4d. per lb. Fair demand.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	2s. 3d. per lb.
Dichloraniline S. Acid	2s. 3d. per lb. 100% basis.
p-Dichlorbenzol	£85 per ton.
Diethylaniline	4s. 3d. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 2½d. per lb. d/d. Drums extra.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol	£84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine	2s. 10d. per lb. d/d.
G. Salt	2s. 3d. per lb. 100% basis d/d.
Monochlorbenzol	£63 per ton.
α-Naphthol	2s. 4d. per lb. d/d.
β-Naphthol	1s. per lb. d/d.
α-Naphthylamine	1s. 3½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.

m-Nitraniline ..	.. 4s. 2½d. per lb. d/d.
p-Nitraniline ..	.. 2s. 2½d. per lb. d/d.
Nitrobenzene ..	.. 5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	.. 2s. 3d. per lb d/d.
Nitronaphthalene	.. 10d. per lb. d/d.
p-Nitrophenol ..	.. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	.. 4s.. per lb. d/d.
p-Phenylene Diamine	.. 10s. per lb. 100% basis d/d.
R. Salt	.. 2s. 4d. per lb. 100% basis d/d.
Sodium Naphthionate	.. 2s. 2d. per lb. 100% basis d/d.
o-Toluidine ..	.. 10d. per lb. naked at works.
p-Toluidine ..	.. 2s. 10d. per lb. naked at works.
m-Toluylene Diamine	.. 4s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	.. £45 per ton, ex wharf London, in glass containers.
Acid, Acetyl Salicylic	.. 3s. 1d.—3s. 3d. per lb., according to quantity. Sales steady. Price firm.
Acid, Benzoic B.P.	.. 2s. 0d. per lb.
Acid Boric B.P. ..	.. Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric..	.. 19s.—21s. per lb.
Acid, Citric ..	.. 1s. 4½d. per lb. Increased demand.
Acid, Gallic ..	.. 2s. 9d. per lb. for pure crystal in cwt. lots. Easier.
Acid, Pyrogallic, Cryst..	. 7s. per lb. Resublimed quality 8s. per lb. Market firm.
Acid Salicylic ..	.. 1s. 6d.—1s. 8d. per lb., according to quantity.
Acid, Tannic B.P.	.. 2s. 10d. per lb. Quiet steady demand.
Acid, Tartaric ..	.. 1s. 1d. per lb., less 5%.
Amidol	.. 9s. per lb. d/d.
Acetanilide ..	.. 1s. 10d.—2s. per lb. More enquiry.
Amidopyrin ..	.. 14s. 6d. per lb.
Ammon. Benzoate	.. 3s. 3d.—3s. 9d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	.. 12s. 6d. per oz. for English make.
Barbitone.. ..	.. 13s. 9d. per lb. Slightly lower. Quiet steady demand.
Benzonaphthol ..	.. 5s. 3d. per lb. spot.
Bismuth Carbonate	.. 8s. 6d.—10s. 6d. per lb.
,, Citrate ..	.. 8s. 6d.—10s. 6d. ,,
,, Salicylate	.. 8s. 0d.—10s. 0d. ,,
,, Subnitrate	.. 7s. 7d.—9s. 7d. ,, According to quantity. Prices recently reduced.
Borax B.P. ..	.. Crystal £29, Powder £30 per ton.. Carriage paid any station in Great Britain.
Bromides	.. Market less firm. Prices uncertain
Ammonium ..	.. 2s. 1d. per lb.
Potassium ..	.. 1s. 10d. per lb.
Sodium.. ..	.. 1s. 11d. per lb.
Calcium Lactate ..	.. 1s. 6d.—1s. 8d. per lb., according to quantity. Fair demand and steady market.
Chloral Hydrate ..	.. 4s. per lb.
Chloroform ..	.. 2s. 6d. per lb. for cwt. lots.
Formaldehyde ..	.. £48—£49 per ton in barrels, ex wharf London. Supplies exceed demand.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free ..	.. 7s. per lb.
Iron	.. 8s. 9d. per lb.
Glycerophosphates—	
Magnesium ..	.. 9s. per lb.
Potassium, 50%	.. 3s. 6d. per lb.
Sodium, 50% ..	.. 2s. 6d. ,,
Guaiacol Carbonate	.. 9s. per lb. Reduced in price.
Hexamine ..	.. 3s. per lb. for bold crystal. Powder slightly less.
Homatropine Hydrobromide	.. 25s.—30s. per oz.
Hydrastine hydrochlor	.. English make offered, 120s. per oz.
Hypophosphites—	
Calcium ..	.. 3s. 6d. per lb., for 28-lb. lots.
Potassium ..	.. 4s. 1d. per lb.
Sodium ..	.. 4s. ,,
Iron. Ammon. Citrate B.P.	1s. 11d.—2s. 3d. per lb. Price recently reduced.
Magnesium Carbonate—	
Light Commercial	.. £36 per ton net.
Light, pure ..	.. £40 per ton.
Magnesium Oxide—	
Light Commercial	.. £75 per ton, less 2½%.
Heavy Commercial	.. £25 per ton, less 2½%.
Heavy Pure ..	.. 2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	.. 57s. per lb. for December delivery.
Synthetic ..	.. 26s.—35s. per lb., according to quantity. English make. Increasing demand.
Mercurials ..	.. Market very quiet. Mercury slightly firmer.
Red oxide ..	.. 5s. 2d.—5s. 4d. per lb.
Corrosive sublimate	.. 3s. 5d.—3s. 7d. ,,
White precip. ..	.. 4s. 6d.—4s. 8d. ,,
Calomel ..	.. 3s. 10d.—4s. ,,
Methyl Salicylate	.. 1s. 9d.—2s. per lb.
Methyl Sulphonal	.. 22s. per lb. Slightly weaker.
Metol	.. 11s. per lb. British make.
Paraformaldehyde	.. 2s. 8d. per lb. for B.P. quality.
Paraldehyde ..	.. 1s. 2d.—1s. 6d. per lb. in free bottles and cases.
Phenacetin ..	.. 5s. 6d. per lb.
Phenazone ..	.. 6s. per lb.
Phenolphthalein ..	.. 5s. 3d. per lb. for cwt. lots. Again lower in absence of active buying.
Potass. Bitartrate—99/100% (Cream of Tartar) ..	.. 86s. per cwt., less 2½% for ton lots.
Potass. Citrate ..	.. 1s. 10d.—2s. 2d. per lb.
Potass. Ferricyanide	.. 1s. 9d. per lb. Quiet.
Potass. Iodide ..	.. 16s. 8d.—17s. 5d. per lb., according to quantity. Steady market.
Potass. Metabisulphite	.. 7½d. per lb., 1-cwt. kegs included, F.o.r. London.
Potass. Permanganate	.. 7½d. per lb. spot. Forward prices higher.
Quinine Sulphate	.. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	.. 5s. per lb. in fair quantities. Supplies exceed demand.
Saccharin ..	.. 63s. per lb., in 50-lb. lots.
Salol	.. 3s. per lb. for cwt. lots. Slightly lower. Limited demand.
Silver Proteinate..	.. 9s. per lb. for satisfactory product, light in colour.
Sod. Benzoate, B.P.	.. 2s. 6d. per lb. Supplies of good quality now available.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite—Photographic ..	.. £13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.

Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.	
Sod. Nitroprusside	16s. per lb.	
Sod. Potass. Tartrate (Rochelle Salt)	75s.—82s. 6d. per cwt., according to quantity. Quiet market.	
Sod. Salicylate	Powder 2s. 1d.—2s. 3d. per lb. Crystal at 2s. 2d.—2s. 4d. per lb. Flake 2s. 6d. per lb. Strong demand. Market firm.	
Sod. Sulphide—Pure recryst.	10d.—1s. 2d. per lb.	
Sod. Sulphite, anhydrous	£27 10s. per ton, minimum 5-ton lots, increasing according to quantity, 1-cwt. kegs included.	
Sulphonal	14s. 6d. per lb.	Little demand.
Thymol	18s. per lb.	

PERFUMERY CHEMICALS

Acetophenone	11s. per lb.	Cheaper.
Aubepine	12s. 6d. per lb.	Cheaper.
Amyl Acetate	3s. ,,	
Amyl Butyrate	6s. 6d. ,,	
Amyl Salicylate	3s. 3d. ,,	
Anethol (M.P. 21/22° C.)	4s. 6d. ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 9d. ,,	
Benzyl Alcohol free from Chlorine	2s. 9d. ,,	
Benzaldehyde free from Chlorine	3s. 3d. ,,	
Benzyl Benzoate	3s. 6d. ,,	
Cinnamic Aldehyde—Natural	18s. 6d. ,,	
Coumarin	17s. 3d. ,,	Again cheaper.
Citonellol	20s. ,,	
Citral	9s. ,,	Dearer.
Ethyl Cinnamate	12s. 6d. ,,	
Ethyl Phthalate	3s. ,,	
Eugenol	10s. 6d. ,,	
Geraniol (Palmarosa)	33s. 6d. ,,	
Geraniol	12s. 6d.—20s. per lb.	
Heliotropine	6s. 9d. per lb.	
Iso Eugenol	16s. ,,	
Linalol ex Bois de Rose	26s. ,,	
Linalyl Acetate	26s. ,,

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.	
Anise Oil	2s. 10d. per lb.	
Bergamot Oil	15s. per lb.	Cheaper.
Bourbon Geranium Oil	30s. per lb.	
Camphor Oil	65s. per cwt.	
Cananga Oil Java	11s. 3d. per lb.	
Cassia Oil, 80/85%	9s. 3d. per lb.	Cheaper.
Cinnamon Oil, Leaf	6¼d. per oz.	
Citronella Oil—Java 85/90%	7s. per lb.	
Citronella Oil—Ceylon	3s. 4d. per lb.	
Clove Oil	8s. 3d. per lb.	
Eucalyptus Oil 70/75%	2s. 2d. per lb.	
Lavender Oil—French 38/40% Esters	35s. per lb.	
Lemon Oil	3s. 4d. per lb.	Dearer.
Lemongrass Oil	5s. 9d. per lb.	
Orange Oil, Sweet	11s. per lb.	
Otto of Rose Oil—Bulgarian	42s. 6d. per oz.	
Otto of Rose Oil—Anatolian	28s. per oz.	
Palma Rosa Oil	17s. per lb.	
Peppermint Oil—Wayne County	45s. per lb.	
Peppermint Oil—Japanese	23s. 6d. per lb.	
Petitgrain Oil	9s. 9d. per lb.	
Sandal Wood Oil—Mysore	26s. 7d. per lb.	
Sandal Wood Oil—Australian	18s. 6d. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before Feb. 10th, they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on Dec. 25th.

I.—Applications

Bamford. Centrifugal separators etc. 29,643. Dec. 10.

Gibbons Bros., Ltd., Marle, and Walter. Furnaces. 29,624. Dec. 10.

Granton and Smith. Separation of suspensoids or solids from liquids. 29,834. Dec. 11.

Hill. Kilns. 29,625. Dec. 10.

N. V. Handelsonderneming Feynald Maatschappij tot Exploitatie van Octrooien. Reducing-agents. 29,454. Dec. 8. (Ger., 7.12.23.)

Soc. d'Exploit. des Proc. Hidoux. Apparatus for mixing pulverulent etc. matter and liquid. 29,405. Dec. 8. (Belgium, 12.12.23.)

Synthetic Ammonia and Nitrates, Ltd. Means for utilising energy of liquids under pressure containing gases. 29,979. Dec. 13. (U.S., 17.12.23.)

Vacuumschmelze Ges. 29,463. *See* VIII.

I.—Complete Specification Accepted

22,249 (1923). Obermiller. Method of giving to air and other gases a definite moisture content. (204,039.)

II.—Applications

Allgemeine Vergasungs-Ges. Distillation of bituminous coal. 29,499. Dec. 9. (Fr., 24.6.24.)

Cox and McDermott. Refining of oils etc. 30,030. Dec. 13.

Dunstan, Pitkethly, and Smith. Utilisation of gas. 29,598. Dec. 9.

Finlayson, Smith, and Woodall-Duckham, Ltd. Removal of sulphuretted hydrogen from gas. 29,732. Dec. 10.

Henshaw, and Holmes and Co. Manufacture of fuel gases 29,826. Dec. 11.

Krauss. Treating fuels at different temperatures. 29,403. Dec. 8.

Lomax, Lucas, and V. L. Oil Processes. Cracking liquid hydrocarbons. 29,560. Dec. 9.

Longhi. Obtaining acetylene etc. 29,701. Dec. 10.

Patart. Gasifying coal etc. 29,561. Dec. 9. (Fr., 11.12.23.)

II.—Complete Specifications Accepted

22,259 (1923). Bloxam (Barnickel and Co.). Treating petroleum emulsions. (225,617.)

27,366 (1923). Morgan. Fuel for internal combustion engines. (225,685.)

IV.—Applications

Heyl. Manufacture of barium azo pulp or dry lakes 29,698. Dec. 10.

Imray. (Farbwerke vorm. Meister, Lucius, und Brüning Manufacture of dyestuffs etc. 29,558. Dec. 9.

[?]—Complete Specification Accepted

[?]485 (1923). British Dyestuffs Corp., Ltd., Baddiley, and Tatum. Dyes of the anthraquinone series. (225,678.)

V.—Applications

British Celanese, Ltd., Dickie, and Rooney. Manufacture of products having basis of cellulose derivatives. 29,720. Dec. 10.

Burlin, Holman, and Leicester. Manufacture of cellulosic material. 29,707. Dec. 10.

Carrier Engineering Co., Ltd., and Groom. 29,948. *See* XIII.

Cross and Engelstad. Manufacture of lignone derivatives. 29,731. Dec. 10.

Kampf. After-treatment of spools of artificial silk, horsehair, etc. 29,829. Dec. 11. (Ger., 3.7.24.)

Pennell. 29,457. *See* XIX.

Plinatus. Producing marble etc. effects on celluloid etc. 29,445. Dec. 8.

Plinatus. Production of coatings for nitrocellulose etc. masses. 29,566. Dec. 9.

V.—Complete Specifications Accepted

14,572 (1923). Lilienfeld. Production of viscose. (212,865.)

31,444 (1923). Soc. Franç. des Crins Artificiels. Conservation of the pellicles of hydrate of cellulose. (224,487.)

VII.—Applications

Spath. Extraction of nitrogen compounds from the air. 29,714. Dec. 10.

Synthetic Ammonia and Nitrates, Ltd. Treating synthesis gases of synthetic ammonia plants. 29,978. Dec. 13. (U.S., 13.12.23.)

VII.—Complete Specifications Accepted

19,612 (1923). Blumenfeld and Weizmann. Preparation of titanium hydroxide. (225,593.)

27,785 (1923). Reitmair. *See* X.

842 (1924). Fabr. [?] de produits chimiques de Thann et de Mulhouse. Manufacture of cyanides from alkaline earth cyanamides. (225,160.)

VIII.—Applications

Frink. Annealing glassware. 29,995. Dec. 13.

Vacuumschmelze Ges. Production of refractory linings for furnace hearths. 29,463. Dec. 8. (Ger., 21.12.23.)

VIII.—Complete Specifications Accepted

6122 (1924). Soc. Progil. Cold enamelling on wood, metal, cement or like surfaces. (215,722.)

8041 (1924). Cachemaille (Westinghouse Lamp Co.). Coating siliceous or vitreous articles. (225,763.)

16,325 (1924). Wade (Dixon Co.). Plate glass annealing lehrs. (225,789.)

IX.—Application

Wilkening. Heat insulating materials. 29,426. Dec. 8. (Ger. 22.12.23.)

IX.—Complete Specification Accepted

14,868 (1923). Ersley. Product for binding dust on roads etc. (225,587.)

X.—Applications

British Thomson-Houston Co., Ltd. Extraction of metals etc. from ores etc. 29,914. Dec. 12. (U.S., 14.12.23.)

Bruninghaus. Production of steel. 29,734. Dec. 10.

Buchalo and Haefeli. Treatment of cast metal. 29,479. Dec. 8. (Switz., 20.11.24.)

Falkenberg. Process for obtaining lead-tungsten alloys. 29,444. Dec. 8.

Marks (Schlesisches Kohlenforschungs Institut). Smelting of ores. 29,449. Dec. 8.

Procter. Application of white Babbitt-metal etc. to iron, steel, etc. 29,441. Dec. 8.

X.—Complete Specifications Accepted

27,785 (1923). Reitmair. Dispersal of mineral raw materials by chemical action. (225,687.)

7519 (1924). Metallbank und Metallurgische Ges. Improving alloys and metals. (213,575.)

12,914 (1924). Hodges. Educting valuable ingredients from ores etc. (225,779.)

18,345 (1924). Thaud, and Soc. Electro-metallurgique de Mont-Richer. Production of magnetic steels with a high content of silicon. (222,088.)

XI.—Applications

Evreynoff. Electric furnaces. 29,808. Dec. 11.

Hatfield. Apparatus for electrosynthesis of gases. 29,371. Dec. 8.

Williams. Electrolyte for accumulators. 29,524. Dec. 9.

XI.—Complete Specification Accepted

233 (1924). Stone and Co., Ltd., and Midgley. Electric storage batteries. (225,719.)

XII.—Applications

Armstrong (Naamlooze Vennootschap A. Jurgens' Margarinefabrieken). Process for distilling fatty acids etc. from oils etc. 29,619. Dec. 10.

Cox and McDermott. 30,030. *See* II.

XII.—Complete Specification Accepted

19,845 (1923). Schou. Manufacture of soap. (225,595.)

XIII.—Applications

Carrier Engineering Co., Ltd., and Groom. Application of cellulose paints etc. 29,948. Dec. 12.

Heyl. 29,698. *See* IV.

Plinatus. Manufacture of varnishes. 29,567. Dec. 9.

XIV.—Application

Pearhey and Skipsey. Vulcanisation of rubber. 29,[?] Dec. 9.

XIV.—Complete Specification Accepted

14,769 (1923). Smith and Delangeaz. Preparation of cold vulcanising rubber compounds. (225,586.)

XVIII.—Complete Specifications Accepted

14,745 (1923). Jena. *See* XX.

22,281 (1923). Quaker Oats Co. Preserving biological materials or specimens. (203,692.)

XIX.—Applications

Pennell. Treatment of laundry effluent etc. 29,457. Dec. 8.

Pickett and Thomson. Treatment of animal matter. 29,467. Dec. 8.

Stevenson. Treatment of milk. 29,954. Dec. 12.

XIX.—Complete Specifications Accepted

22,281 (1923). Quaker Oats Co. *See* XVIII.

22,821 (1923). Ravnestad. Clarification or purification of liquids. (225,635.)

XX.—Applications

Farbwerke vorm. Meister, Lucius, und Brüning. Manufacture of complex gold compounds. 29,159. Dec. 8. (Ger., 2.6.24.)

Kane, Thomson, Strange and Graham, Ltd., and Synthetic Products Co. Production of acetone etc. 29,678, 29,679. Dec. 10.

Merck. Preparation of homogeneous oleaginous bismuth preparations. 30,036. Dec. 13. (Ger., 13.12.23.)

N. V. Handelsonderneming Feynald Maatschappij tot Exploitatie van Octrooien. 29,454. *See* I.

XX.—Complete Specification Accepted

14,745 (1923). Jena. Production of specific ferment remedies. (225,585.)

XXI.—Complete Specifications Accepted

24,707 (1923). Kitsee. Producing integral multi-coloured screen on photographic blanks. (225,659.)

24,714 (1923). Namias. Obtaining positive photographic pictures by means of powdered pigments. (205,092.)

25,161 (1923). Watson. Composition for use in washing photographic plates, films, or the like. (225,664.)

XXII.—Application

Plinatus. Explosives. 29,713. Dec. 10.

JOURNAL *of* THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council of Pure and Applied Chemistry

which consists of Representatives from

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals and the Royal Agricultural Society.

VOL. 43 NEW SERIES | LONDON, NOVEMBER 7, 1924 | No. 45

EDITORIAL

THERE are only three or four men who would have had the temerity to address the members of the Society of Chemical Industry on recent experiments in Protection and only one, our President, Mr. Woolcock, could have performed this feat so well as he did. He has one unique qualification: he knows, as only those who have been intimately concerned in some of these experiments can know, how they have been conducted, and with what result. Mr. Woolcock avoided a discussion of the merits of Free Trade and Protection; at times he resembled a skilful skater on thin ice which would hardly bear him, at other times he explained clearly and judicially the advantages and disadvantages of the three different varieties of Protection which are now practised in this country and the conditions which should guide those who have to choose between these three varieties. He carefully avoided, as the saying is, partiality on the one hand and impartiality on the ...er one. Twenty years ago many of us read with ...tisan avidity the pamphlet by Mr. Arthur Balfour ...Insular Free Trade and the many speeches by ...Joseph Chamberlain. We knew several selected ...sages by heart and were familiar with a great ...ss of controversial literature and statistics which ...h could interpret to his own liking. In all this ...w of oratory and feast of argument there was no ...h careful and scientific a treatment of the subject ...Mr. Woolcock gave us last Monday. He indulged ... no prophecy; he told us how the different pro...ctive measures fitted into our British system and ...ow in our essentially British way the measures were ...onceived and put into operation. We heard in the ...ubsequent discussion a reference to certain funda...ental and immutable principles; Mr. Woolcock ...ndicated the means of detecting which principles ...re fundamental and immutable, and the effect on ...them of some variable conditions. The prosperity of the chemical industries of this country is of vital interest to every chemist; Mr. Woolcock's address helps us to understand how Protection affects certain parts of this industry; it seems to us that his address is singularly novel and opportune, and that every chemist, whether he is interested in politics or not, should read his careful and weighty words and remember his conclusions. This address is a striking departure from the technical and analytical discourses which have formed a large proportion of those delivered to meetings of sections. The discussion of the paper clearly showed that the topic, controversial as it might have been in less skilful hands, was handled so as to interest the audience and to set many scientific minds thinking how a number of political questions could be investigated with equal care and caution and the great problems confronting us be reduced to simple terms freed from the oratory which is necessary to stimulate the great mass of the population but is a cloud and a distraction to those who have been trained in scientific methods.

* * *

Thus with the year seasons return; the shooting season has been prematurely closed by the election season; the dining season has begun. The joint dinner of the Society of Chemical Industry and the Chemical Industry Club will be held on Friday, the 14th inst., at the Hotel Victoria, Northumberland Avenue. The Society and the Club have many things in common besides the dinner. When we consider how popular the Club is, and how much it is frequented by chemists and by others who are glad to be associated with chemists, it is somewhat surprising that such a Club was not founded many years ago. Well, better late than never, as the astronomer said when he missed his train. Founded it was in the fulness of time and now flourishing; it is a permanent and valuable part of our corporate life. The dinner will be a pleasant gathering, the numbers will be considerable, the music and speeches will prevent any prolonged and bitter arguments between those who doubt, and those who advocate, the validity of alternate polarities or the electro-negative character of zinc. There will be an atmosphere of content; sweet are the thoughts that savour of content; there will be harmony, such harmony is in immortal souls. We trust that those who partake of the feast will murmur as they leave: "Fate cannot harm me, I have dined to-day." But let not the dinner be a mere meal; let us regard it as a contribution to that better understanding of each other and of ourselves which will lead to more concerted action, more community of thought, the highest common factor of human experience, united action towards an important end, the advancement of human happiness and human prosperity. These are dark days; we can all help to brighten them. One of the greatest duties which man has is to be cheerful; to a certain extent this power grows by experience; the longer we live the happier we become. And in the month of November this duty is unusually necessary.

ECONOMY IN THE GENERATION AND UTILISATION OF STEAM. PART I

By CHAS. F. WADE, A.M.I.Mech.E., A.M.I.E.E.

When we talk about "coal," it is not sufficiently realised that this is a general name for a *class* of material rather than a substance of definite composition and characteristics. Coal may range from the almost pure carbon known as anthracite to the semi-lignite with no uncombined carbon in its composition, and consisting mainly of volatile hydrocarbons, moisture and incombustible matter or ash. Between the two extremes mentioned there is an infinite variation in the composition. While, on the one hand, the variation in the properties of coal presents the valuable feature that we have a selection of what is virtually a large variety of combustible material, each variety of which has certain properties which make it of especial value for specific purposes, on the other hand the variability, if neglected, may lead to considerable financial loss through insufficient attention to the particular properties required in the fuel for the special work to which it is to be applied.

Only too often is the purchase of fuel for manufacturing works left in the hands of a quite non-technical Stores Department which asks for coal of some particular name or decides upon purchase on the basis of size and price only. Such a method of buying almost invariably leads to financial loss, because even with coal from the same seam and pit large variations will occur from time to time in the composition of the fuel supplied, whilst the label on the truck or name of coal on the invoice does not always give a correct description of the material supplied by the agent.

This series of articles being particularly concerned with matters relating to steam raising, we will confine ourselves to the discussion of the desirable properties to be looked for when selecting a suitable fuel for economical steam raising.

Calorific Value

Although selection of fuel by calorific value against price will be a quite unsatisfactory basis of purchase by itself, yet this test forms an essential preliminary without which ultimate commercial valuation cannot be carried out. The test for calorific value is the starting point, and *the starting point only* from which we proceed to make further investigations as to the physical properties of the fuel so as to arrive at the actual suitability of the fuel for our purpose and to calculate the necessary deductions to be made from the theoretical heat value as disclosed by the calorimeter. The calorimeter test gives no idea whatever of the nature of the fuels tested, and will correctly give similar heat values for a number of fuels having widely varying characteristics in use and ultimate commercial values.

Many people have attempted to arrive at a valuation of coal on the basis of B.Th.U. of heat value per unit of price. This system would be scientifically correct if conditions of use were uniform in every case, and the ash content and percentage hydrogen of the fuel were constant in composition and amount respectively. Selection by calorific value will only be correct where the coal is already known to be suitable in respect to its proportion of volatile matter and fixed carbon and the nature of its ash. Even then the commercial value of the fuel will not bear a regular proportion to the calorific value, as the calorific value does not decrease nearly so rapidly as the practical value with increase of ash content.

Practical Selection of Coal

This involves a simultaneous investigation of the various properties of the fuel in the laboratory, together with careful observation of the behaviour of the coal under working conditions, combined with careful tests of the various losses associated with the particular fuel under observation.

In addition to the test for calorific value the other laboratory investigations consist of proximate analyses of the fuel so that its composition in terms of moisture, volatile matter, "fixed" carbon and ash will be determined, together with visual observation of the coking properties of the coal and the nature of the ash. It is usual to include a sulphur determination in addition to the proximate analysis, but for steam raising purposes this is of little value and may be omitted without detriment to the pra[illegible] value of the results obtained.

Proximate Analysis

This consists essentially of a progressive heating of the fuel under varying conditions of temperature and air admission. A detailed description of the various stages of this analysis is outside the scope of this article, but a summary of the procedure is given herewith.

(1) *Moisture* is determined by heating a weighed sample of the finely powdered fuel in a current of air in an air-jacketed oven until there is no further loss of weight. The difference in weight before and after heating gives the uncombined moisture in the fuel. As with all the stages of proximate analysis, this test must be carried out under standard conditions, preferably those recommended by the Fuel Research Board and published in their Interim Report on Methods of Analysis of Fuel (H. M. Stationery Office).

The moisture test should be carried out on the air-dried fuel or a sample of the fuel which has been powdered and placed in a desiccator overnight. Free moisture is not a characteristic feature of any fuel, but is influenced mostly by weather conditions in transport and does not therefore affect the real value of the coal.

Water also exists in the combined form in coal mainly as carbohydrates of the cellulose type, whilst hydrogen and oxygen also occur in other portions of the coal substance, but the original combinations of these elements are but slightly known at present. Empirical formulæ are available by which a close approximation to the actual percentages of oxygen and hydrogen may be arrived at, but a knowledge of the percentage of hydrogen is the more important point in determining the actual practical value of a

bituminous coal or other fuel containing appreciable proportions of hydrogen.

(2) *Volatile Matter* is determined as a percentage of the fuel by heating a sample in a covered crucible without access of air until the whole of the volatile hydrocarbons are expelled. In order to obtain uniform results the temperature employed must be standardised because very large variations in volatile matter will be caused by heating at different temperatures owing to the variation in the nature of the reactions. The temperature now adopted as a standard is 900° C. The residue from the volatile matter test is the coke, consisting of the "fixed" carbon and ash of the original fuel.

(3) *Percentage Ash* is obtained by roasting a sample of the fuel in a muffle at a high temperature and in a current of air until the whole of the combustible is removed and only incombustible residue remains.

These three tests constitute the usual routine of proximate analysis, the percentage of fixed carbon being obtained by difference from the other three determinations.

Hydrogen in Fuel.—This may be determined directly by the ordinary methods of organic analysis, in a combustion tube; but this is not usual in the majority of practical fuel laboratories. Hydrogen is usually calculated by means of some empirical formula, such as Diederichs', which is as follows :—

$$H = V \left(\frac{7\cdot35}{V + 10} - 0\cdot013\right),$$

where H = percentage of hydrogen in the combustible.

V = percentage of volatile matter in the combustible,

and combustible = Volatile matter plus fixed carbon

The total hydrogen in the air-dried coal will therefore be the hydrogen as found above plus one-ninth of the moisture.

The importance of the hydrogen content lies in the effect of the water produced by the combustion of hydrogen in absorbing a very large amount of heat which is carried away in the waste gases in the form of latent heat of evaporation, in addition to sensible heat and superheat. In the calorimeter the whole of this heat is recovered, owing to the condensation of the water of combustion, thus giving a higher figure of heat value than can be obtained in practice where condensation does not take place before the gases reach the atmosphere.

Coke.—The coking properties of the coal may be very well observed during the test for volatile matter, and note should be made of the hardness and coherence of the coke produced. Heavily caking coals are to be avoided as far as possible when selecting steam coal for average working conditions because of the great difficulty in obtaining complete combustion with moderate draught without excessive opening of firing doors for slicing and poking.

Ash.—The principal point to be noticed about the ash is its fusibility. Low fusing-point in ash is generally caused by iron compounds which exercise a strong fluxing action on the other constituents of the ash. Such low fusing-point is shown in the proximate analysis by the colour of the ash, which varies from dark chocolate brown in the very fusible ash to pure white in which case the iron content is negligible, and the fusing point very high. Low-fusing ash reduces the practical value of a fuel much more than a high-fusing ash. In addition to the actual reduction in heat value, due to the incombustible matter, there is its action in closing up the firegrate spaces so that combustion is retarded. Again the molten slag entraps and envelops appreciable quantities of carbon so that combustion is arrested, however much air is admitted to aid in the process. Incidentally it may be remarked that American coals are very troublesome in this respect, and it is for this reason that pulverised fuel is finding such wide adoption in the States.

Apart from questions of direct economy in the use of fuel with a low-fluxing ash, considerable additional expense in the maintenance of water-tube boiler brickwork is caused by the fluxing action of the iron compounds on the brickwork, which requires much more frequent renewal than when high-fusing ash is present. This also applies to the cast-iron firebars, which burn and fuse much more rapidly with the low-fusing ash. Owing to this trouble the testing of ash fusibility is a regular feature in fuel investigations in many modern American plants.

Working Tests of Fuel

Before actual placing of a contract for the supply of a fuel a preliminary order should be given for a truck or so, of each coal which has been offered and has shown itself to be of apparently suitable character from tests of calorific value and proximate analysis, so that observation may be carried out upon the behaviour of the fuel under working conditions. Such observation should be carried out upon a boiler provided with a water meter on its feed-pipe, so that the rate of evaporation may be observed and regulated.

During the working test of the coal the following observations should be made :—

Test of waste gases by means of the Orsat apparatus and determination of the maximum percentage of carbon dioxide obtainable without carbon monoxide being present.

Temperature of waste gases.

Maximum possible rate of evaporation without carbon monoxide being present in the waste gases.

Average percentage of carbon dioxide in the gases during the whole of the trial.

Coking characteristics of the fuel, also tendency to slagging ash or otherwise.

Power required by draught fans.

Amount of fuel used and ashes removed.

Ultimate Evaluation of the Fuel

Having obtained the necessary laboratory and boiler house data as described, we are now in a position to form an accurate idea of the practical value of each fuel offered by various tenderers, in terms of B.Th.U. per unit of cost.

The first deduction to be made from the calorimeter value of the coal is the unavoidable loss due to water vapour or steam in the waste gases, caused either by moisture or combined water in the original fuel,

or by combustion of the hydrogen. This loss, known as the hydrogen loss, is obtained from the following formula :—

Loss per lb. of fuel =

$$9H([212-t]+970{\cdot}4+\{0{\cdot}48[T-212]\})$$

where

H = Hydrogen in fuel expressed as a fraction.
t = Temperature of air in degrees F.
T = Temperature of air in waste gases in degrees F.

The higher or gross calorific value of the coal, less the above deduction, gives us the lower or nett calorific value at the temperature of the waste gases for the particular case under observation. The commercial value of the fuel is not, however, by any means represented by the lower value already arrived at, for a further deduction will have to be made for the sensible heat loss in the waste gases when working under the most favourable conditions. The method of calculating these losses would require a very considerable amount of space to describe, but the formulæ may he obtained from various books on the subject.

The next deduction to be made is the loss due to unburned carbon in the ash heap; this is obtained by taking the difference between the absolute ash as found by proximate analysis and the percentage of ashes removed and calculating this as a percentage of the fuel used with the assumption that the increase of weight is due to carbon with a calorific value of 14,544 B.Th.U. per lb. This final deduction leaves us with the practical thermal value of the fuel and, under some conditions, is a measure of the commercial value.

Where coals are being selected from a large number of qualities which vary widely in calorific value and ash content the cost of labour in firing and ash removal will have to be taken into account. This is of considerable importance when considering the purchase of low-grade fuel at what appears to be a particularly advantageous rate if based upon calorimeter tests. Not only are labour charges and power costs increased when low-grade fuels are used, but the practical working calorific value will be a smaller percentage of the calorimeter value than with high-grade fuels owing mainly to the physical effect of the ash in reducing the possible thermal efficiency obtainable, as well as the maximum possible output of steam per boiler unit and per man employed.

Although the reduction below the theoretical thermal value does not increase very rapidly at first with increase of ash percentage, yet the rate of reduction increases very rapidly with ash increase until with a coal containing 40 per cent. of ash the practical value is zero under normal conditions of draught and firegrates.

If it is desired to take full advantage of the low price at which low-[illegible] coals are usually offered, the conditions un[illegible]ich such fuel is to be used will have [illegible] be ma[illegible]table for the purpose, but this wi[illegible] be a [illegible] proposition unless it is intended [illegible] use low-grade fuel permanently.

Coal should be selected for any purpose with as low a percentage of volatile matter as can be economically burned with existing conditions and possible requirements as to a reducing atmosphere ; it should have as low an ash content as possible, and the ash should be as free as possible from iron compounds ; it should not form a dense coke if required for steam raising ; it should have the highest possible calorific value per unit of price ; and for steam raising purposes it should never be purchased in a larger size than about 4-inch cobbles.

THE MAKING OF A COMPLEAT CHYMIST

By HENRY E. ARMSTRONG

(*Continued*)

Students are not often allowed to make experiments—seldom, if ever, encouraged to do so. They are spoon-fed on demonstrations and verifications. Think this out, please ! Lecturers are falsely said to *show* experiments—you can't declare the result of an *experiment* in advance, though you may foresee it ; an experiment is a question put, not an assertion ; you can give demonstrations to justify faith in your statements. Assistants are properly called *Demonstrators* ; the Experimenter, let alone the Philosopher, has not hitherto been officially recognised.

If you study Bernard Shaw's *Joan of Arc* you will realise that the lecturer who gives demonstrations is just a miracle worker. We no longer believe in the miraculous and fortunately we do not always trust lecturers ; their miracles may often be read more ways than one, as books may ; you will remember what Stevenson says in the passage I quoted. Only some of us, far too few, are seeking to make experiments.

It will be the office of those among you who become " thinkin' men " and acquire " bloomin' souls," when you go into schools, to deal with a very awkward situation. You will desire to be logical but the examiners controlling you—probably the Board of Education Inspector also—will only take the old coin. You must slip your logic in unawares. No headmaster will suffer a teacher who makes boys think—if they did they would find out the absurdity of the school system. To-day, Oxford and Cambridge, in particular, make the rational teaching of Science in schools impossible by setting questions, in the College entrance examinations, which are not fit even for their fellows. Boys are asked to gas about Ions and Electrons and all sorts of high falutin' matters but never a question on real fundamentals. No worse service to science teaching was ever done than that of allowing the Intermediate Examination to be taken from school. The Board of Education special courses have an equally bad effect. The work can't be done properly under school conditions without cramming. School is the place in which as broad a general foundation as possible should be laid : it hasn't the scientific atmosphere ; in school there should be no teaching of special branches of scientific activity, no chemistry even, certainly no elaborate makers' apparatus—only a general course bearing upon the affairs of life.

This may equally be asserted of the period at the University up to the first degree—this should be the

medal course but no clasp should be held without the medal. Each special subject might well have its clasp. The growing tendency to give degrees in special subjects is one that appals me. Thoroughness of knowledge and breadth of outlook are the essential qualifications in every profession to-day. Scarcely a problem in chemistry can be dealt with from a single point of view; nor can any problem in practice. The one-sided treatment to which problems are being submitted is leading us nowhere in particular and is a great waste of time and energy.

The burden now laid upon the student is an intolerable one—far greater than he can bear; what is worse, he is asked to memorise so much that he has no time left in which he can learn to think. The practical work is not well thought out and there is far too little of it. So-called research work is brought in at the end, too late to give the mental balance which didactic and dogmatic teaching have all but destroyed.

Chemistry needs cleaning up—a thorough stock-taking of what we have and a clear decision as to its value. We need to develop a true philosophy of our science which the student could assimilate:—

> O for a Muse of fire, that would ascend
> The brightest heaven of invention.
> A kingdom for a stage, princes to act
> And monarchs to behold the swelling scene.

Of our kingdom we are sure, for it is the world, nothing less; princes to act are wanting, who will unfold the drama we have composed in terms that monarchs and the common people will understand. members of my class are the greatest sinners—are "over-full of self affairs" and make no reasoned effort to come down from our stilts. We are in no way ourselves possessed by the scientific spirit. Let me give an illustration from my own person. Recently I have had to ask why I was born so soon. Prof. Bancroft, *the* authority on theoretical questions in the U.S.A., has been moved to discuss the *Action of Metals on Nitric Acid* and to come to the broad conclusion Acworth and I came to in 1877, that the metal merely displaces hydrogen from the acid and that products other than a nitrate are due to secondary interactions—that, as Bancroft put it, the interaction is a case of electrolytic corrosion. My remark upon this is, that if Bancroft be right and I but plagiarised him, therefore, in 1877, chemists generally must have been very obtuse—for none has accepted the view. The story of nitric acid is a disgraceful muddle in the text books. The case is made worse by the fact that, from 1885 onwards, I have persistently contended that all chemical interchange is electrolytic in character. No one has either accepted or denied my explanation. No other explanation has been offered. The Arrhenic hypothesis merely states that action is between ions; nothing is said as to the conditions which determine interaction. The subject is calmly left untouched. Chemists are satisfied to be without any clear conception of the nature of the process by which they gain their living. Such appears to be the psychology of the scientific mind—it can flatly say: "I won't think! It doesn't!"

Some of you may remember how the sage, Sembobitis, answered Balthasar: "My Lord, science is infallible but the learned often err"; how, when Balthasar had discovered a star and urged the Sage to admire it, "Sembobitis did not see the star because he would not see it. Wise and old, he did not like novelties." On this issue, I would have you study Walter Pater's *Marius the Epicurean* (Macmillan and Co. 3s. 6d.).

The learned should be made to wake up. Here the *Compleat Chymist* will come in—he must be a person trained to reason; doubting all things, ready, at all times, to discuss.

To give a technical tone to our talk, let me go a little further into this question of the acid function and also refer to certain fictions which are commonly put upon the student and which he is weak enough to accept. Just as in old days the doctrine of original sin was accepted by the good, water is made an original sinner in chemistry—it starts life bad, we are told. It is dissociated into its ions, though ever so little. The logic of this assertion is ridiculous. It is based upon the statement of one Kohlrausch that water which he had purified so far as he was able still had a certain slight electrical conductivity. The assumption made is, that the water he examined *was pure*. What does *pure* mean? To my thinking, the thing itself—free from all impurity. It is inconceivable that the Kohlrausch water can have been pure, in this sense: no vessel we can use is to be had free from surface impurity, even if it be not to some slight extent itself soluble. The doctrine of the original sin of water is, however, so firm a matter of faith among chemists that it is useless to protest. Now that Bishop Barnes is coming to Birmingham, perhaps a new miracle may be enacted: he gave away the Church's doctrine of original sin at the British Association meeting, at Cardiff, two or three years ago; perhaps, under his patronage, your Professor will become a convert—or should I say pervert—to the doctrine that water lacks morality through evil associations and would not in itself be bad could it be forced away from their company.

You know the Arrhenius speculation—I use the word advisedly, as it never was *a theory*—about electrolytes generally: that they exist in solution, more or less, as free ions; hence their activity. Though a conceivable hypothesis, it is in no way a necessary one and there is not a shred of proof that it holds; the facts, in large measure, are against it. Yet it remains fashionable at the end of nearly forty years. Who will say that chemists are not like the proverbial old woman; that their motto is not the simple converse of her's—"I know it's untrue but I believe it"? Let us hope that some day soon, if not the knight of the *Daily Mail* some other doughty champion of scientific truth, may tilt them into unbelief. I learn that tailors are at last advising their customers that the cult of the turned-up trouser is nearing its end—so anything may happen; I fancy, indeed, that the day is not far distant when the crowd *will* see that their king has no clothes. I hope you remember your nursery tales.

The short skirt of the male chemist to-day is the acid reduced to its hydrogen ion: his nakedness is

astounding, his modesty nil in wearing so little. The fashion is but a fashion—there is not the slightest reason to suppose that the acid radicle is not co-operative in all interactions of acids.

These just by way of example of problems to which the *Compleat Chymist* may well turn his attention, straws which show how carelessly blows the wind of belief among us, how doctrinaire we are apt to be, how difficult it is to be philosophical. I lay no claim to superiority but in life there must be times when the man of thought feels that, like Gilead P. Beck, he has struck 'ile. Such thought was mine in 1877. As my orbit seems to be 44 to 47 years, I feel that I may well await the time when my *unbelief* of 1885-6 and onwards in ions as freelovers becomes current as the *belief* of our tribe.

Last, let me ask—is the *Compleat Chymist* possible? Only by the method of very gradual approach and never the finished product! First, let us recognise that only the few can approach completeness. Special provision should be made for the drones, not to overburden them, whilst training them to be competent artificers, yet seeking to charge them with a sufficient burden of logic, so that if the "thinkin' man" arise in them at any time, a "bloomin' soul" may have the chance to frame itself. I have known more than one such case of late development in after-life among my pupils: suddenly, some chord has been struck to which there has been real response. Will you believe it, I was desperately afraid, at one time, that the now Sir (William) Pope would never make a chemist; that he might degenerate into a mere mathematician. However, one day, something happened: all at once his marvellously dextrous fingers were at work in every direction; the "bloomin' soul" *was* there and in full operation.

To return for a moment to nitric acid. If, as Faraday maintained, the terms chemical and electrolytic action be synonymous, if all chemical interchange be electrolytic in its nature, the acid can act only in one way and, as it were, in one place: the radicle H at the one and the radicle NO_3 at the opposite "contact" with the metal. The only possible product of the interaction of a metal and nitric acid (given the necessary third component of the electrolytic system) are hydrogen (H_2) and the nitrate. The secondary products are due to the reduction of the acid—by what? Not by the hydrogen, even when nascent—*i.e.*, still in circuit: this cannot be, as hydrogen is formed away from the acid radicle and the radicle can act neither in two places nor in two ways at once. The primary reduction of the acid must be due to some other cause. We know as a fact that nitric oxide is the primary reducing agent and it is probable that hydrogen comes into operation only after a reducible "nitrous compound" has been formed by the interaction of nitric acid and this oxide.

The *Compleat Chymist* will be an artist and—as I have said elsewhere in speaking of the work of Sir James Dewar—the experience of ages goes to show that Art of every kind is a matter of individual expression and that it cannot brook control. He must, therefore, as far as possible, be left to his own devices and mainly learn by doing. Neither at school nor at college, to-day, can the student learn to help himself nor to think for himself: he is so ceaselessly tutored and directed; he must work at play as well as play at work; he has no time in which he can cultivate hobbies and interests, little chances of becoming a good Naturalist. The true chemist is but little else: the world is his oyster, to open with stirring rod, test tube and balance.

As chemistry is before all others *the* experimental science, the early period of study at school and then at college should be spent in real experimenting—not in mere verification work. In other words *Research*, as we are pleased to call it to-day, should come at the beginning not the end of the course and be continued all through it. It is the attitude that counts in learning chemistry. Most students begin research work after the art of experimenting has been memorised out of them. As I have said elsewhere, in addressing the Institute of Chemistry, I would have students spend much time in familiarising themselves with materials, but the work should be done from their own reading not from any laboratory manual. Just as the bug-hunter collects, sets and arranges his insects, so the chemist should hunt down this and that compound and bring it into being on his bench. The Squeers principle of learning to spell winders by cleaning 'em has to be applied in chemistry. I am not speaking at random when I give this advice.

As to reading—most reading is mere memorising: the art of reading, to which I have already referred, is rarely learnt by the student. As Sir Nathaniel says (*Love's Labour Lost*):—

> He hath never fed of the dainties that are bred in a book;
> He hath not eat paper, as it were; he hath not drunk ink;
> His intellect is not replenished; he is only an animal,
> only sensible in the duller parts.

He hasn't pegs in his closet to hang the clothes upon which the examiners would have him own: so he just throws them at random into the press and may or may not be able to find this or that article when called upon to produce it. He has no joy in his clothes. The only way to read with effect is to acquire interests—best through practical work—and ever to consider the bearing of what is read upon these interests—in short, what use can be made of it.

Desultory reading leads nowhere. It is possible to read an account several times without finding anything in it—then something happens to make it of interest and when read again it may be found to be full of point. To read with effect it is necessary to have a philosophy:—

> Study is like the heaven's glorious sun,
> That will not be deep-search'd with saucy looks;
> Small have continual plodders ever won,
> Save base authority from others' books.

As to subjects of study. Just as all roads lead to Rome, so chemistry now travels upon all roads and the chemist must at least be able to wander sympathetically upon most of them. Before all things he must have real feeling for current elec-

tricity—as chemistry and physics are inseparably linked in all the phenomena of chemical interchange.

My feeling is that a chymist may be compleat without knowing a vast deal—if only he have acquired a certain outlook. It is not only undesirable but wrong to qualify the term by any prefix. "Research Chemist" is a contradiction in terms, as the man who has the "bloomin' soul" of the chemist is never otherwise than an experimentalist; those who have not are not chemists but mere artificers. Recollect always, it's the bloomin' soul that counts. The great example is that set us by Emil Fischer in the marvellous work he did in laying solid foundations for the future treatment of vital problems in terms of structural chemistry. He never called himself otherwise than Chemist and was proud of the significance of the title; he knew that he was no biologist. To-day we have a school yclept "*Biochemists*," who, for the most part, are but crude bits of chemists and still smaller bits of biologists; in like manner, the physical chemist is neither physicist nor chemist but only a fragment of each: physics and chemistry are essentially one subject. To work with a product of vital origin, such as starch, doesn't make the worker a biochemist; nor does working with enzymes, which are vital agents. Your Professor of Brewing, the pupil of whom I am especially proud, has done remarkable work on Starch. In a recent account of the inquiry, he speaks of the discovery of the several constituents of starch giving "a new conception of its nature," adding that this was "the result of the 'pure' chemist working in concert with the biochemist." This is just an "aside" to help the lame dog along: the conception comes from work done by an exceptionally qualified chemist—one of the Samurai. There ain't no such thing as a Biochemist: the "pure" chemist don't exist—to be compleat he must be very impure, a mixture of many "ists."

The spirit of Paul's message to the Corinthians should be more with us. "Now I beseech you, brethren, that ye all speak the same thing and that there be no divisions among you; but that ye be perfectly joined together in the same mind and in the same judgment."

Infinite injury is being done to our great subject by the present-day loose specialisation, built upon an insufficient foundation of primary knowledge and entirely lacking in breadth of outlook. The result is that problems are so narrowly envisaged that far too little of the work done is of practical value and our science is in serious danger of sacrificing public esteem, through lack of that culture and outlook which Huxley hoped would be gained in Mason's and like colleges.

Our Universities should take stock of the situation and consider how far they are on the downward path in failing to pay proper, adequate attention to scientific method—the method of Zadig; to consider by what means and how far method may be made the first charge upon their madness, as a corrective of the herd instinct innate in man and a means of raising his tribal efficiency.

FORTHCOMING EVENTS

Nov. 10. Biochemical Society, Physiological Department, St. Bartholomew's Hospital, 5 p.m. "Micro-estimation of Urea in 0·2 c.cm. of Blood," by G. Thomas; "Excretion of Salicyluric Acid after Ingestion of Sodium Salicylate by the Human Subject," by E. Holmes; "Carbohydrate Enzymes of Starch-free Monocotyledons," by R. E. Chapman; "Effect of Ultra-violet Irradiation of Environment on Growth and Calcification of Rats fed on Vitamin A-deficient Diet," by E. M. Hume and H. Henderson Smith; "Effect of Insulin on Cholesterolæmia," by G. A. Harrison; "Observations on Glucose and Lævulose Tolerance Tests," by R. L. Mackenzie Wallis.

Nov. 10. Institute of Brewing, Engineers' Club, 39, Coventry Street, London, W., at 7.30 p.m. "Preservative Properties of Hops," by A. Chaston Chapman.

Nov. 11. Society of Chemical Industry, *Birmingham and Midland Section*, University Buildings, Edmund Street, Birmingham, at 7.15 p.m. (1) "Studies in the Acenaphthene Series, Part I: 2-Amino-naphthene," by Prof. G. T. Moran and H. M. Stanley. (2) "Researches on Molybdenum Salts," by W. Wardlaw, F. H. Nicholls and R. L. Wormell. (3) "Observations on the Higher Fatty Acids," by G. T. Morgan and A. R. Bowen. (4) "Researches on Residual Affinity and Co-ordination, Part XXIII: Trialkylstibine Derivatives of Platinum and Palladium Chlorides," by G. T. Morgan and V. E. Yarsley.

Nov. 12. Leicester Literary and Philosophical Society, *Chemistry Section*, The Museum, Leicester, at 8 p.m. "Water Supply," by S. F. Burford.

Nov. 13. Textile Institute, *London Section*, 38, Bloomsbury Square, London, W.C. 1, at 5.45 p.m. "Textile Fibres Produced Within the Empire," by J. S. M. Ward and F. R. Econ.

Nov. 13. Oil and Colour Chemists' Association, 8, St. Martin's Place, Trafalgar Square, London, W.C. 2. "The Examination of Varnishes: Drying under Standard Conditions: Water Absorption," by J. A. F. Wilkinson and E. F. Figg.

Nov. 13. Society of Chemical Industry, *Chemical Engineering Group*, Kelvin Room, Engineer's Club, Coventry Street, W. Discussion on "Chemical Works Costs," opened by F. M. Potter and followed by H. C. Marris. W. J. U. Woolcock, C.B.E., will occupy the chair.

Nov. 13. Institute of Metals, *London Section*, Royal School of Mines, South Kensington, at 8 p.m. "Oxidation, with Special Reference to Thin Films," by Prof. T. Turner.

Nov. 13. University of London, St. Thomas's Hospital Medical School, S.E. 1, at 4.30 p.m. "Enzymes," by Prof. J. Mellanby. Also on Nov. 20 and 27.

Nov. 13. University of London, Bedford College, Regent's Park, London, N.W. 1, at 5.15 p.m. "Atomic Structure and Quanta," by Prof. W. Wilson.

Nov. 14. Institute of Metals, *Swansea Section*, University College, Singleton Park, Swansea, at 7.15 p.m. "The Inner Structure of Alloys," by W. Rosenhain.

Nov. 14. University of London, King's College, Strand, W.C. 2, at 5.30 p.m. "Scientific Method," by Prof. L. T. Hobhouse.

Nov. 14. Society of Chemical Industry, *Glasgow Section*, jointly with the Ardeer Chemical Club and the Institute of Chemistry. "Chemical Pottery," by J. G. Roberts.

SOCIETY OF CHEMICAL INDUSTRY

CHEMICAL INDUSTRY DINNER

The Autumn Dinner, which will be under the auspices of the Society of Chemical Industry and the Chemical Industry Club, will be held in the Edward VII Rooms of the Hotel Victoria, Northumberland Avenue, London, W.C. 2, on Friday, November 14, at 7 for 7.30 p.m., and will be presided over by Mr. W. J. U. Woolcock, C.B.E., President of the Society.

It is hoped that members who intend to be present and who have not yet applied for tickets will do so as soon as possible, in order to facilitate the seating arrangements.

SUSPENSION OF ENTRANCE FEE

As an inducement to Chemists to become members, the Council has resolved that no entrance fee shall be paid by members joining the Society in 1925.

A form of application for membership was inserted at the end of this Section in the issue of the Journal for October 17, and it is hoped that it may be used to introduce a new member for next year.

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

VOL. IX (1924)

This volume is in course of preparation, and an order form will be sent out in due course with the application for the annual subscription for 1925.

The list of subjects dealt with and the names of the authors are as follows :—

Plant and Machinery	S. G. M. Ure.
Fuel	J. W. Cobb and H. J. Hodsman.
Gas—Destructive Distillation—Tar Products	W. B. Davidson.
Mineral Oils	S. J. M. Auld.
Colouring Matters and Dyes	E. H. Rodd.
Fibres, Textiles, Cellulose, and Paper	S. H. Higgins.
Bleaching, Dyeing, Printing, and Finishing	A. J. Hall.
Acids, Alkalis, Salts, etc.	P. Parrish.
Glass	E. A. Coad-Pryor.
Ceramics, Building Materials, and Refractories	W. J. Rees.
Iron and Steel	C. O. Bannister.
Non-Ferrous Metals	C. A. Edwards.
Electro-Chemical and Electro-Metallurgical Industries	J. N. Pring.
Oils, Fats, and Waxes	H. M. Langton.
Paints, Pigments, Varnishes, and Resins	C. A. Klein.
Indiarubber	D. F. Twiss.
Leather and Glue	D. M. McCandlish.
Soils and Fertilisers	H. J. Page.
Sugars, Starches, and Gums	E. Eynon and J. H. Lane.
Fermentation Industries	H. L. Hind.
Foods	G. W. Monier-Williams.
Sanitation and Water Purification	J. H. Johnston.
Fine Chemicals, Medicinal Substances, Essential Oils	H. King.
Photographic Materials and Processes	W. Clark.
Explosives	J. Weir.

LONDON SECTION

There was a large attendance at the opening meeting on November 3, when an address was delivered by the President, Mr. W. J. U. Woolcock, C.B.E., entitled "Experiments in Protection," of which an abstract follows :—

I need hardly say that in dealing with this subject I do not propose to treat it in any party political spirit. I do, however, feel that it would be useful that we should discuss together and endeavour to understand the experiments in protection which have been tried in Chemical Industry. I shall confine myself to a discussion of the methods, and not the principles of protection. There are, in general terms, only three methods which can be used to protect artificially the industries of a country :—(1) Subsidy. (2) Prohibition of Imports, except under Licence. (3) Tariff.

(1) The method of subsidy was used fairly extensively during the war. In theory it presupposes that the industry to which it is to be applied is of direct national importance and that every taxpayer is therefore concerned in its maintenance. If this is accepted it is logical to make all pay for what is for the benefit of all. In practice, however, it is a very difficult method to work. It entails the necessity of deciding to whom the subsidy shall be given; more difficult still is it to determine the amount of the subsidy. A subsidised industry always lies under the implication that it is inefficient, although the the necessity for the subsidy may be due to causes outside the control of the industry, such as depreciated currency in foreign countries and the differences in exchange values. For these reasons although the method of subsidy was used during the war, and in war time is less objectionable than in peace time, it has fallen into disrepute.

(2) *Prohibition and Licence.*—Experience has shown that where there already exists an organised body of consumers of a class of commodities or where such can be organised, the method of prohibiting the importation of these goods except under licence can be utilised with comparatively little friction. The consumer invariably feels that if there is a prohibition of foreign imports he will have to pay more for his goods. He argues that there would be no need for prohibition if the British goods were cheaper. He is, however, interested in the maintenance of the British industry quite apart from national patriotic motives, because if the foreigner has no competition in Britain, the prices the British consumer will have to pay will be higher than those charged in other foreign countries with competitive industries.

If I use the Dyestuffs (Import Regulation) Act, 1920 to illustrate this method it will perhaps make these general observations clearer. The origin of the Dyestuffs (Import Regulations) Act, 1920, and also of the Safeguarding of Industries Act, 1921 can be found in the report of the Committee on Commercial and Industrial Policy presided over by Lord Balfour of Burleigh, and usually called the Balfour of Burleigh Report. In June, 1916, the Economic Conference of the Allies held in Paris passed among other things the following resolution: "The Allies decide to take the necessary steps without

lelay to render themselves independent of the enemy countries in so far as regards the raw materials and nanufactured articles essential to the normal development of their economic activities." Following this he then Prime Minister (Mr. Asquith) appointed the Balfour of Burleigh Committee.

At the close of the war the country was provided ith a mass of emergency legislation under the Dence of the Realm Acts, and, by reason of the interetation placed upon it, with machinery under the ustoms Consolidation Act of 1876 for the restriction imports into this country. The legality of the strictions for which the Act of 1876 was evoked was sted in December, 1919, when Mr. Justice Sankey's dgment declared them to be illegal except in the se of certain specific classes of goods such as firems, ammunition, explosives, etc. The effect of the dgment was to throw wide open the door to all nds of foreign imports. To meet this situation the overnment introduced the Imports and Exports egulation Bill, which met with considerable oppoion and was dropped. The situation with regard the manufacture of dyestuffs in this country then came very acute and at the close of the year 1920 Dyestuffs (Import Regulation) Act was passed. is was followed six months later by the Safeguard- of Industries Act. The two Acts together protect their different ways, the former by prohibition and ence, the latter by tariff, most of the industries ich the Balfour of Burleigh Committee regarded as ey" industries.

he Dyestuffs Act, which came into operation on uary 15, 1921, and continues in force for ten rs, prohibits the importation of all synthetic anic dyestuffs, colours and colouring matters, all organic intermediate products used in the nufacture of any such dyestuffs, colours, or uring matters except under licence. The Act owers the Board of Trade to issue licences for the ortation of any of the articles covered by the and constitutes an Advisory Committee to advise Board as to the issue of such licences. The cedure to be followed by an importer begins with atement of the name and quantity of the dyestuff ntermediate which he desires to import, together his reasons for making the application. As the of the Act prohibits the importation of article, the onus of convincing the Advisory mittee of the necessity for importation is on the orter. The Act was passed with "a view to the guarding of the dyemaking industry"; therefore uate cause must be shown before the Committee advise that a licence should be issued. On the er hand, although it finds no expression in the there is an implied condition that, when necessary licence must be issued. The question arises, on hat grounds can the importer claim that a necessity as arisen for the issue of the licence? It is suggested hat the strongest case is made out when it is proved that: (a) The dyestuff for which the licence is required is not itself made in this country; (b) that no suitable substitute is available; and (c) that it is required by a consumer for immediate use in his business and for a stated purpose. If conclusive evidence on these three points is furnished to the Committee a licence would be issued almost automatically. An application for a licence merely on the ground that it is desired to make a speculative purchase which may or may not result in a sale is not likely to be regarded with favour by the Licensing Committee. But between these two extremes there is room for a considerable argument, and the constitution of the Advisory Committee as provided by the Act makes it certain that the application will be considered from several points of view.

The Advisory Committee is composed (Section 2 and 3) of five persons concerned in the trades in which goods of the class prohibited to be imported by this Act are used, three persons concerned in the manufacture of such goods, and three other persons not directly concerned as aforesaid. One of the last-mentioned is appointed Chairman by the Board of Trade, and in practice, if he is absent, one of the "other persons" acts as his deputy. In the main it is a technical Committee with a sufficient number of non-interested persons to hold the balance fairly between what are bound to be two opposing views. The consumers' representatives may be expected to take a somewhat pessimistic view of the possibility of a British dye-maker producing an adequate substitute for a foreign dye; the representatives of the dye-makers are apt to take a too optimistic view of the capabilities of the British dye-maker. The truth, as usual, lies between the two, and the "other persons" taking a disinterested view assist in finding it.

The machinery set up by the Act has worked quite well mainly because there is on the side of the users of dyestuffs a very efficient Colour Users' Association. Only where the products which it is desired to protect are used by a great number of unorganised concerns is the method of prohibition and licence likely to fail. The only real difficulty which arises is the amount which the consumer has to pay to maintain the industry in the country. It will be obvious that the claim to import a foreign commodity may be made on one of two grounds, namely, that no identical British product is made, or that although such a product is made its cost is so high that the firms who have to use it are handicapped in their business by its price.

The practice under the Dyestuffs Act is to put the onus of proof that the British product is equivalent in quality to the foreign dyestuff upon the British manufacturer. This question can fairly easily be settled in the testing laboratory. The onus of proof that a colour user is being placed in an unduly disadvantageous competitive position is on the user, and is not proved so easily. It is, in practice, impossible to take each individual case and demonstrate that a possible sale of, say, 100 pieces of coloured cloth has been lost because of the cost of the dye in the cloth. Yet some kind of limit has to be fixed especially if only one maker is making a particular dyestuff. Where a number are making the same colour the internal competition compels each maker to seek greater and greater efficiency and consequently a lower price. But here arises one of the fundamental problems of industry. If the total quantity required of one particular colour can be made in one works, the increased output should make

for a lowering in price to the advantage of the consumer. This is true when the foreign market is open as a check on prices and a stimulus. When, however, you prohibit the importation of the foreign article and concentrate the manufacture in one works you have to provide some other stimulus to efficiency.

The problem to be solved is, How much can the consumer afford to pay in order that the industry shall be established in this country. The answer, of course, is, the amount he estimates it would cost him if he had to rely entirely on the foreigner. This can only be an estimate. In practice the only thing to be done is to fix an arbitrary factor with which to work and agree that as long as the British price is not greater than that arrived at by the use of the factor it will be considered that the user is not being placed in an unduly disadvantageous competitive position.

3. *Tariff* Our only example of protection by means of a tariff is to be found in the Safeguarding of Industries Act, 1921. Here it is desired to protect a variety of industries the products of which go to an even greater variety of consumers. Obviously the method of prohibition and licence would be difficult to apply, and hence the tariff method is adopted. The Safeguarding of Industries Act swept into its net all the other industries, apart from dyestuffs, which had been reviewed by the Balfour of Burleigh Committee. It dealt with synthetic organic chemicals, fine chemicals, optical glass, optical instruments, wireless valves, magnetos, arc-lamp carbons, and a number of other things. It also dealt with the protection against dumping. I have little to say about the dumping part of the Act except that in the form in which it was drafted it was of very little use. I do not, however, think that no machinery can be devised for this purpose. The first part of the Act, dealing with the safeguarding of "key industries," has worked and has done something to establish firmly the industries in this country.

The Act provides that there shall be charged, levied and paid on the goods specified in the Schedule to the Act on their import into the United Kingdom a Customs duty of 33⅓ per cent. The Schedule contains a number of headings of classes of articles included in this part of the Act, and only in very few instances are the articles themselves enumerated. The Act therefore also provided in order to avoid disputes whether a particular article is covered by the Schedule, that the Board of Trade may issue from time to time lists defining the articles which are to be taken as coming within the general descriptions in the Schedule. The effect of the publication of the name of any article in such a list is the same as though the article itself were named in the Schedule. This list was first published in September, 1921, and certain amend[illegible] since been made in it.

I have [illegible] on a subject which is not per[illegible] top[illegible] which you are accustom[illegible] me[illegible]ngs. I have done so becau[illegible] the commencement, the Society holds [illegible] position in that it represents both the Scien[illegible] the Industrial sides of Chemistry. These sides have been too far apart in the past. I think perhaps your place as chemists has not been sufficiently emphasised in the industrial world. I feel even more certain that chemists have not fully recognised the necessity of studying the industrial problems as well as the scientific. For this reason, among others, I have gone out of the beaten track and sought in this way to encourage you to realise the interdependence of the scientist and the industrialist. The success of British Chemical Industry is as vital to the chemists as to the industrialists. If members of the Society, realising this, work for this end, then the Society will have more than fulfilled the task for which it was founded.

NOTTINGHAM SECTION

A discussion on "Textiles" was held jointly with the Faraday Society, at University College, Nottingham, on October 30, the Chairmen being Sir Robert Robinson, K.B.E., and Mr. G. J. Ward, M.I. & S.I. Dr. W. Lawrence Balls, F.R.S., sketched the general conditions of the textile problem, and pointed out that the unit from the textile point of view was the single hair or fibre, a unit which to all intents and purposes had only two dimensions, being entirely flexible in the third. With this material three-dimensional persons and furniture must be covered. A scale model of a cotton fibre made of rubber tubing ½ in. in diameter would be 60 ft. long. All the surface properties of such fibres became enormously important. The slivers moved over one another along these surfaces in the process of drafting, which, although invented in 1745, is one of which we knew least. By trial it had been found that the rollers should be covered with leather, should have true surfaces, and machinery had been perfected so that defects in yarn and fibres formerly due to faults in the machinery must now be considered to be inherent in the properties of the raw material. The exaggeration of these properties in one direction, which was peculiar to the material of the textile industries, opened a new field of applied physics for which the author proposed the term "Trichodynamies" in 1918.

Dr. J. Barratt, of the Research Department, Woolwich, then summarised his work on the lustre produced in cotton by mercerisation and on the measurement of the transparency of a fabric. Photographs of fabrics stretched and unstretched during mercerisation showed a much smoother surface in unstretched material, and the disappearance of the folds and creases would account for the superior brilliancy and increase in the intensity of light regularly reflected. In order to measure the intensity of light reflected at various angles a special form of Joly's photometer had been designed. Most of the increased lustre shown in a mercerised fibre was due to the light regularly reflected in a direction along the length of the fire. This regular reflection was intermediate in intensity between that from glass and that from the unmercerised thread. The diffuse reflection was greater with unmercerised fabrics, in which the lustre due to the single fibres was enhanced. A mercerised fabric also showed a distribution of very bright and very dull points. By the same photometer the relation between the total transparency and the thread transparency (*i.e.*, the percentage of the

light falling on the threads alone which was transmitted by them) could be determined. Thus, the thread transparency 24·8 of a muslin was increased to 30·8 by a "hard finish."

Dr. Guy Barr described the various methods of investigating the action of sunlight, and of artificial lights, such as the mercury arc, approximating to sunlight upon fabrics, especially those used in the construction of balloons. The distribution of destructive power in the spectrum had been investigated by Scheurer, Aston, Ramsbottom, and Glendinning; and it had been conclusively shown that the weakening of cellulose threads was chiefly due to rays of wave-length less than 4000 A.U.; cellulose was extremely sensitive to the rays of very short wave-length less than 2950 A.U., which were present in the light of the mercury arc, but absent from sunlight. The breaking strain, reduced from 120 to 102 lb. per in. by light of 6250 to 5330 A.U. transmitted through red glass, fell to 12 when transmitted through violet glass (6300 to 3230 A.U.) and to 2 with no glass. The fabric was partly protected by pigmented dopes, the most effective being lead chromate. These changes were due to oxidation, for they are almost inhibited in absence of oxygen, and cotton which had been insolated answered the tests for oxycellulose.

Dr. S. A. Shorter then gave a detailed account of his theories relating to the behaviour of woollen fabrics during manufacture under the heads:—(1) The elastic properties, (2) the absorption of moisture and its effect on the elastic properties, and (3) the surface structure of the film. The creeping of wool fabrics when rubbed was due to surface structure, which also caused the shrinkage in milling. The absorption of water could be treated thermodynamically, as heat was given out during absorption and the atmospheric humidity necessary to produce a given moisture content increased with the temperature. Thus wool saturated and apparently dry at one temperature became obviously moist on heating. Some experiments were described which seemed to show that the wool fibre was perfectly elastic; if the stretching was slow an extension of 30 or even 40 per cent. might be followed by complete recovery. Many reasons were adduced in favour of the theory that the wool fibre consisted of an elastic envelope enclosing a material which behaved as a viscous liquid. The extensibility was greater when the wool was wet. On exposure to boiling water the elastic envelope underwent a change similar to the annealing of a metal.

Dr. Barratt remarked on the variability in the results which express the action of light on textiles. There might be some other agency at work, such as a chemical action resulting in an increase of acidity, and the greater resistance of wool might be traced to the fact that it is not so easily attacked by acids. Experiments might profitably be made upon quite neutral fabrics. Dr. Balls enquired how far the effect of bacteria had been eliminated, and said the conditions governing the formation of a free water film on different fibres were different: where none existed the results might be considered free from the suspicion of bacterial or mould action. He did not claim that such action seriously vitiated the experiments, but it might mask or intensify the effect of light. The viscosity method of following the changes produced by light was very interesting; the changes in viscosity were five or six times more rapid than those in tensile strength. He suggested that the light disintegrated the fibres longitudinally and not transversely. Mr. Burford, illustrating the importance of the time factor in the recovery of fibres from stretching, said that pellets of sugar moistened with acid and then dried did not char for a long time when kept in air-tight bottles. Dr. Prideaux asked if quantitative experiments had been carried out on the effect of the standard sunlight which could be obtained in some tropical regions. Sir Robert Robertson pointed out the great differences between the solar spectrum and those of the mercury and carbon arcs. The daylight lamps used in "fadeometers" and the 1000 c.p. pointolite lamp gave results more in accordance with daylight.

Dr. Barr, in reply, said the cotton was washed thoroughly before the experiments. No elaborate precautions were taken against micro-organisms, as their effect was almost negligible compared to that of light, and those which would cause damage were destroyed, especially by the short wavelengths which were most destructive to the fabric. Some experiments had been made in the tropics, but the difficulties were great. The "daylight" lamp was not intended to give the same ultra-violet intensity as sunlight, but rather to give the same ratio of distribution in the spectrum. The explanation of the cause of the differences between the viscosity and tensile strength figures was most suggestive; was it partly due to differences in the adhesion of separate fibres? The initial high viscosity of unexposed cotton was probably due to a highly polymerised cellulose forming the outer cuticle. It was fairly well established that the outer layer, present in extremely small amount, was different from the rest; and it was probably the disintegration of this which caused the rapid fall in viscosity. The Chairman mentioned as evidence for the existence of highly polymerised cellulose the fact that in nitrating to obtain the most nitrated (most viscous) product, a portion was more highly nitrated. It contained, say, 13·8 per cent. of nitrogen, but, on stabilising, the nitrogen went down to 13·4 per cent. Replying to Mr. Heyes, Dr. Barr said that copper numbers of the solutions of exposed fabrics had not been determined. He intended to try this, but thought that the differences would be much less than those shown by the viscosity.

Dr. Bramley asked whether the effect of the rate of drafting and the temperature had been measured. Was there any connexion between the fibrils mentioned by Dr. Balls and the lustre produced by mercerisation; did they become more evident after this process? Mr. Palmer emphasised the probability that the breaking of yarn was really a surface slipping effect. In silk this effect was negligible. The strength of cotton fibre was as great as that of silk and very much in excess of that of cotton thread. Dr. Shorter inquired as to the effect of humidity on the single fibre. Was it, like the yarn, made stronger? Dr. Balls could not give

a definite opinion as to the effect of twisting and drafting on the fibres. Information on fibrils would be found in a paper read before the British Association and published in the *Empire Cotton Review*, January, 1923. The use of cotton appeared to be justified only by its great tensile strength, which in fine and coarse varieties, and allowing for air spaces, worked out at 17 to 18 tons per square inch. This, however, was not translated into the tensile strength of the yarn. Dr. Barratt remarked that the wetting of fibre increased its apparent tensile strength by increasing its extensibility. Mr. Dunford understood from the papers that wool could be stretched and allowed to recover a number of times. Would that not have a tendering effect? When hosiery goods were heated with water, would not the colloidal material be leached out or unevenly distributed?

Mr. Palmer enquired whether Dr. Shorter could apply his theory to fibres other than wool. He had not been able to apply the theory of retraction to silk or artificial silk. Was the time of retraction for wool equal to that of extension. Dr. Balls said the failure to obtain parallel results with silks was to be expected in view of the difference in structure; silk being an extruded substance quite different from the highly cellular cotton and wool. Ought there not to be some relation between the maximum extension of the wool fibre and the dimensions of the net-work, on the supposition that the elastic network was rigid and had a kind of "lazy-tongs" structure? Dr. Shorter said that the 40 per cent. extensibility was only found with cold-treatment; hot water had a permanent effect. There was a loss of about 1 per cent. on boiling, rather less if the material was acid. All fibres showed more or less the effect of the extension and recovery, but cotton and silk gave permanent extensions. When wetted, wool only swelled in width, but silk also in length. The time of recovery was always longer than that of extension. Theoretically it was infinite. If one wetted the fibre and extended slowly the results were much more uniform. He found groups which gave a uniform extension of 35 per cent. and others of 42 per cent. which bore out Dr. Balls' suggestion. Mr. Brimley suggested that the degree of perfection of the framework is a function of the ratio, amount of water in cell to saturation capacity. Dr. Shorter said he did not think the water content affected this property much. Dr. Balls said he could not give any opinion as to the mechanism of swelling. Owing to the structure, the fibre was anisotropic, and the longitudinal swelling, which was easy to measure, was different from the tangential or radial. He had long been trying, but unsuccessfully, with Mr. Hancock, to measure the changes in radial dimensions, but had only succeeded in doing so with the fibre immersed in liquid, which of course altered its properties. Dr. Bramley enquired whether the elasticity of fibres was impaired after treatment with organic solvents. Dr. Shorter said that benzene and such liquids had no effect, but alcohol caused swelling. Mr. Edwards understood that treatment with organic liquids would remove the natural grease; after scouring it was necessary to add some fat. Mr. Heyes asked how Dr. Shorter's theory agreed with the microscopic structure—the outer cuticle enclosing spindle shaped cells? Dr. Shorter said that the structure referred to in his paper was sub-microscopic. Dr. Barrett suggested that the time of shear might have a great effect on the time of set. If the structure were ultramicroscopic there must be a minimum shear to produce any movement in a viscous liquid. Was Dr. Shorter's description of the frame-work as perfectly elastic hyperbolic? If Dr. Balls had measured the change of length and of volume, that should give the change in cross section. Dr. Shorter said that the densities had been determined in benzene and in water. He assumed that the former was the true one. Mr. Calam, referring to Dr. Shorter's theory, suggested that the cell walls might be simply the dividing lines between large colloidal molecules, which in recovering after stretch re-established a molecular equilibrium. Dr. Shorter said that the effect of sudden shear agreed with the viscous liquid theory. The proof of perfect elasticity was the complete recovery on wetting.

Mr. Barber asked whether the viscous substance could be coagulated before extension, and Dr. Shorter replied that it was coagulated when dried, and the material was then not elastic. Mr. Pentecost enquired whether, in the work on the effect of light, precautions had been taken against mildew and bacterial action, which were the chief causes of deterioration of lace curtains. Dyed cotton apparently was not so liable to deterioration. Dr. Barr thought that it was not established that the growth of fungus on cotton was the chief cause of damage. Dr. Bramley referred to the use of dyes and mordants and wished to know whether the protection was similar to that of an opaque covering or was due to selective absorption. Mr. Hancock suggested that the growth of mildew might be checked by mercerisation.

The Chairman said he could fully realise the importance of this kind of work in the rigid control of manufacture. During the war they introduced a new propellent made from nitro-cellulose of a low nitration, dissolved in alcohol-ether instead of acetone. The new process worked well on the experimental as well as on the large experimental scale. A factory was built at Gretna and the manufacture proceeded smoothly for three months. Then in some batches the cords emerged, not continuously, but in jerks. The cotton was traced to two works, in one of which the waste cotton was boiled in open pans instead of keirs. The viscosity of this cotton was not correct, and the introduction of technical control and viscosity tests quite removed this trouble.

LIVERPOOL SECTION

The first meeting of the session was held on October 31 in the Midland Adelphi Hotel, Mr. Edwin Thompson in the chair. Nearly ninety members and guests were present. The chairman announced that Lord Leverhulme had very kindly given to the Section the fee that he had received as Messel Lecturer, in the form of 20 per cent. Preference shares in Messrs. Lever Brothers, Ltd., the interest to be

utilised for the purpose of an annual prize for chemistry students at the University of Liverpool.

The President, Mr. W. J. U. Woolcock, C.B.E., addressed the meeting on: "Publicity in Chemical Industry." Referring to the Society he said that its position was unique among the organisations representing chemical science and chemical industry, in that it represented both the scientific and the industrial sides of chemistry. This position presented very great opportunities for usefulness, and the influence which might be exerted by its thousands of members was of great value to the community. Its responsibilities, therefore, were extremely heavy and at the moment were not being shared fully among all the chemists and industrialists engaged in the industry.

He then dealt with the financial position of the Society and gave an account of the internal working of the Society's affairs. At present, owing to the depression in the industry, the burden of carrying on the various societies to which chemists belong was becoming intolerable, and steps were being taken to co-ordinate the work of the societies to prevent overlapping and to reduce expenses. As an instance, he mentioned the co-operation between the Society and the Chemical Society for the joint production of chemical abstracts.

The duty placed upon societies of conveying scientific information to their members entailed a very considerable expense, and he thought that still further avenues might be explored which would lead to a closer co-operation between the various societies and a diminution in the expenditure of each of them.

The President then discussed the necessity of informing the general public of the work on which chemists were engaged, and the impossibility of building up a reputation without publicity. As an example of such work he instanced the British Empire Exhibition, the publication of "Chemistry in the XXth Century" and its effects on scientists in other countries, and to the pamphlets which had been prepared for the public giving some information as to various branches of chemical industry. In conclusion he stressed the point that chemical industry and chemical science were so brought together that it was impossible for the industry to succeed without the chemists, and there would be no chemists unless the industry were there to find employment for them. After a full discussion a very hearty vote of thanks was accorded to the President for his address.

POTASH DEPOSITS IN SPAIN

According to A. Marin (*Bol. Inst. Geol. España.* 4, 44), the potash basin in Catalonia is 26 miles long by 9 to 10 miles wide, and the potash is found between 656 and 2624 feet, in depth like that of the Alsatian deposits. The thickness of the bed is about 13 ft. and take 6½ ft. as an average, exploration has shown the presence of 268,000,000 t. of potash (K_2O) at workable depths, equivalent to 2000 million tons of potash salts.

CORRESPONDENCE

A PATERNAL OPINION

Sir,—You will, I believe, admit my right to assume something of a paternal attitude towards you. Let us come to the point at once and see page 1083 of your last issue—"racy" or "funny" editorials and too much blocking of the traffic by the triumphal car of Antimony. There are some in the West Riding of Yorkshire and elsewhere who do not like it; they accept jokes "wi' deeficulty" and prefer a lorry load of oil of vitriol to imaginary mediæval chariots.

I have been watching you, not without some anxiety, treading a very hazardous path. It is only a convention—and a very dreary one—that a weekly professional or trade paper should be all solid phase pudding. It is all part of the grimness of the desk and factory world—grind, grind, grind, and then for refreshment of spirit, off elsewhere and another kind of raciness than yours—rather pinker.

I confess that I was at first against you; I thought you were overdoing it. People need gentle leading. But I have felt no quarrel with your Editorials on the ground of their being light-minded. I will not send you to the hatter by saying how well I think of them. Your chief mistake is in dropping so easily—not *à la* Silas Wegg into poetry (others are getting that habit, and I have no objection)—but into Latin. I don't quarrel with the Latin; it is good to let people see the aptness of the Romans and the conciseness of their speech; but when you quote Latin you should do as Addison and his friends did in the *Spectator*—give the best English version in a footnote. It is an affront in these days to fling Latin about as if it were current coin.

As for your historical, political, economic and other allusiveness, go on as you are doing—carefully. You have, however, committed one grave offence. In your last editorial you put that it was said of Lockyer that "he sometimes forgot that he was the editor and not the creator of *Nature*." No, no, no, that was never said. I know no adequate Latin quotation for your offence. But there is something in Urdu that will appeal equally to you and your readers *wuh tum se kahta hai ki meri zaban men mujh se bolo.* What happened was this: someone said to Lockyer, "remember you are the editor—not the author—of *Nature*." And, by the way, *Nature* used to print comic verse by Sylvester, and I believe no one was a penny the worse.

The great danger to a really well-educated man is that he will offend by exactly that which would most please his equals—the assumption that they are at least as well-educated. Now, it has been hinted lately that the education of the modern chemist is not always perfect in its comprehensiveness. Care, therefore, is needed. Never mind a few grim faces, but—oh! that Lockyer lapse!—I am, Sir, &c.,

S.

THEORY OF SUBSTITUTION IN AROMATIC COMPOUNDS

Sir,—In read in your issue of October 24 (p. 1057) the following statement, attributed to Dr. B. Flürscheim, in the report of a discussion during which the induced polarity rule was considered:

"The theory assumed that when oxygen anp nitrogen are both present, the former is the negative key atom."

Three months ago I had to correct Prof. Ingold on the same point (this vol., p. 769). The original memoir (*Mem. Manch. Lit. and Phil. Soc.*, 1920, **64**, 111, 5) does not admit of any misunderstanding on this matter, and it may therefore be gathered that Dr. Flürscheim is not conversant with the "theory" which he criticises nor, *a fortiori*, with its possible applications.

Those who prefer Werner's theory of the distribution of valencies in carboxylic acids to Thiele's theory, and others who desire support for the view that para-bonds are present in aromatic amines and phenols, will doubtless find Dr. Flürscheim's theory acceptable. Others, who, like myself, consider Werner's carboxylic theory wholly at variance with the facts, including what we know of the very process it was devised to explain, will continue to think that Dr. Flürscheim's theory is untenable, while gratefully acknowledging many invaluable suggestions which he made in constructing it.—I am, Sir, &c.,

The University, Manchester ARTHUR LAPWORTH

NITROGEN FIXATION BY GREEN PLANTS

Sir,—I was interested to read your editorial on the fixation of elementary nitrogen by green plants. But—"honour to whom honour is due"—this subject was studied carefully by Mr. Thos. Jamieson, F.I.C. (late lecturer in Agriculture at Aberdeen University). The results of his researches and his opinions on this subject were met with such derision by his agricultural contemporaries that latterly he was forced to live the life of a recluse and, may I say, a heretic. His little book on "History of the Progress of Agricultural Science in Great Britain" (C. and R. Anderson, Edinburgh) is worth reading not only by those interested in this subject, but also by our younger chemists, particularly his remarks on the "retarding influence on progress of dogma and authority."

Jamieson's conclusions were confirmed by Zemplen and Roth (in Hungary) and Pollacci and Mameli (in Italy). Now comes fresh confirmation as noted in your editorial.

Personally I have never needed much convincing on this subject, as from a considerable experience of field geology I found trees of considerable dimensions growing from solid igneous rocks—not in cracks or crevices, but in rocks devoid of soil. The only obvious source of the nitrogen in such circumstances is the atmosphere.

In the case of trees there is a possibility that bacteria may play some part in fixing the nitrogen, as I have observed bacteria in the healthy living cells of many leaves.—I am, Sir, etc.,

Queen's Cross, Aberdeen JAMES STRACHAN

PERSONAL AND OTHER ITEMS

Prince Arthur of Connaught will open the Ramsay Laboratory of Chemical Engineering at University College, London, on November 12 at 5 p.m.

Dr. F. S. Fowweather, M.Sc., F.I.C., has been appointed to the new lectureship in chemical pathology in the University of Leeds.

At the recent election of office-bearers of the Royal Society of Edinburgh, Principal J. C. Irvine was elected a vice-president, Dr. A. Lauder a secretary, and Professor Sir James Walker a councillor.

Dr. H. M. Tory, President of the University of Alberta, will become permanent chairman of the Research Council of Canada.

Major J. Price, M.C., has been elected president of Price Bros., Ltd., succeeding his father, the late Sir William Price.

Mr. M. L. Davies, of Toronto, has been elected president of the Standard Chemical Co., Ltd., of Canada.

Mr. G. Scott Robertson has been appointed professor of agricultural chemistry in Queen's University, Belfast.

The Institution of Electrical Engineers has given 100 guineas to the Cavendish Laboratory at Cambridge, as a mark of appreciation of the electrical researches carried out there by Sir Joseph Thomson, Sir Ernest Rutherford, and other Cambridge physicists.

The Royal Institute of Scientific Industrial Research of Sweden has awarded its gold medal of the first class to Johannes Ruths, D.Sc., for his invention of the steam accumulator which equalises intermittent load on boilers in factories and power plants thus securing greater facility in working and substantial economies in running costs.

The late Sir Samuel Turner, of Turner Brothers Asbestos Co., Ltd., left estate of the gross value of £496,644, with net personalty £490,796.

The late Mr. John Allen, chairman of Frederick Allen and Sons (Poplar), Ltd., chemical manufacturers, left £15,389.

The death is announced of O. H. Steudel, a partner of the firm of Kraft and Steudel, Dresden, manufacturers of photographic papers.

The late Prof. Sir W. Bayliss, F.R.S., left estate of the gross value of £102,387, with net personalty £86,274.

Nitrogen Fixation at Niagara

It is reported that operation of the Casale process for fixing nitrogen by the Hooker Electro-chemical Co. at Niagara Falls is proving very successful and plans are under consideration for doubling the capacity of the plant.

Proposed German Dye Amalgamation

It is reported that negotiations are in progress for the amalgamation of all the German dye factories to form one large company in place of the looser union provided by the Interessen-gemienschaft. This movement is said to have been induced by the attempts of the French and United States dye manufacturers to come to terms with the Swiss industry. It is also rumoured that the French Compagnie Nationale des Produits Chimiques may come to terms with the Swiss makers. One step towards the German amalgamation has

already been made by the pooling of German dye agencies in Japan. It is now proposed to build up one selling organisation for the whole world and to "go in for greater specialisation," whilst reducing manufacturing costs.

First Forecast of the Indigo Crop of British India

From reports received from provinces which contain about 85 per cent. of the total area under indigo in India, the total area sown is estimated at 98,100 acres, which is 40 per cent. below the corresponding estimate of last year. The total yield of dye is estimated at 17,200 cwt., as compared with 30,400 cwt. last year or a decrease of 43 per cent. The weather has not been favourable, and the present condition of the crop, on the whole, is reported to be only fair.—(*Ind. Tr. J., Oct.* 16, 1924.)

Electrical Precipitation

On October 30, Sir Oliver Lodge delivered the seventh of the lectures on the relation of physics to industry which have been arranged by the Institute of Physics, the subject being "Electrical Precipitation." Of the two kinds of electrical precipitation, natural and artificial, Sir Oliver Lodge first dealt with the latter, which began with his work in 1884 on the electrical deposition of smoke or steam. This work had been applied on a large scale by the lecturer's sons in this country, and Dr. Cottrell in the United States to the recovery of metallic fume and the purification of blast-furnace gas. Over 200 plants of this type were now installed and very large amounts of solid matter were collected in some of them. Natural electrical precipitation was described as the process by which clouds turn into rain, a subject which was treated at length.

All-Australian Exhibition of Manufactures

Although the bulk of Australia's wealth is derived from her primary products, her secondary industries cover a very wide range, a fact which was made evident by the All-Australian Exhibition of Manufactures which was opened on September 13, showing the wide range and diversity of Australian manufactures. Machinery, furniture, textiles, electrical apparatus, cameras, boots and shoes, motor tyres and rubber goods, matches, cooking-stoves, chemicals, articles made from copper, brass and aluminium—all made in Australia—were displayed, and in most cases the manufacturers showed not only their finished products, but also the manner in which they were made. There are over 18,023 factories in Australia, employing, in all, 395,425 hands. Salaries and wages paid last year amounted to £71,133,000, light and fuel cost £8,659,000, and materials cost £186,082,000, leaving a margin of £60,621,000 for miscellaneous expenses and profits, making a total of £326,497,000. The total output 10 years ago was valued at only £161,500,000—less than half the value to-day.

Diseases of Pitch and Tar Workers

The Home Office, Factory Department, has issued a leaflet (Form 1782) relating to epitheliomatous ulceration as affecting pitch and tar workers and advising that such workers should seek attention at once when small warts or ulcers develop on the skin.

COMPANY NEWS

LANGDALE'S CHEMICAL MANURE CO., LTD.

According to the report, the profit for the year ended June 30, 1924, was £2,825, to which is to be added the balance brought forward from last year of £110 8s. 1d., making a total of £2,936. It is proposed to pay a dividend of 2½ per cent. (less income tax), which amounts to £2,725, leaving a balance to be carried forward of £210 17s. 3d. During the year it has been necessary to decline many orders which, owing to reduced prices consequent upon increased severity of foreign competition, would have involved heavy loss, and the output of manures has consequently been reduced. The coming season appears a little more hopeful as prices have been increased abroad. The demand for sulphuric acid has been heavily curtailed by the closing down of many coke ovens in the district, which it is feared will continue until there is improvement in the coal and iron industries.

SANTIAGO NITRATE CO., LTD.

The gross profit for the year ended June 30 was £17,637 (against £20,019 in 1922–23), and the net profit £12,420 (against £12,692), to which is added the balance of £10,196 brought in. A dividend of 7½ per cent., less tax, is to be paid, leaving £10,616 to be carried forward. The "oficina" was reopened on April 15, and it is stated that there will be no difficulty in producing all the nitrate necessary to meet its proportion of any sales the producers' association may make.

HART ACCUMULATOR CO.

An interim dividend of 5 per cent. on the ordinary shares has been declared. An interim of 5 per cent. in respect of 1923 was paid early this year.

CASTNER-KELLNER ALKALI CO.

The accounts for the year to September 30 show a profit of £288,052, compared with £263,188 last year. To this amount should be added £36,331 brought forward, making a total of £324,383, from which should be deducted debenture interest £7297 and interim dividend £80,000, leaving a balance of £237,086, out of which a final dividend of 14 per cent. is proposed, making 22 per cent. for the year (against 20 per cent.). The sum of £75,000 is again to be carried to the suspense account, leaving £22,087 to go to next account.

The Antofagasta Nitrate Co., Ltd., has published the prospectus of an issue of £400,000 7 per cent. second mortgage debenture stock, which will be secured by a specific mortgage in favour of the Law Debenture Corporation to rank immediately after the existing 6½ per cent. first mortgage debentures.

The Anglo-Chilian Nitrate Co., Ltd., has declared an interim dividend of 2s. per preference share and 2s. per ordinary share, or 10 per cent. in each case, less tax. Last year the interim dividend on the ordinary shares was 5 per cent., tax free.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech.	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder	£47 per ton.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 10s. per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Copper Sulphate	£25 per ton.
Methylated Spirit 64 o.p.—	
Industrial	2s. 7d.—2s. 11d. per gallon, according to quantity.
Mineralised	3s. 8d.—4s. per gallon, according to quantity.
Nickel Sulphate / Nickel Ammon. Sulphate	£38 per ton d/d. Normal business.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¾d. per lb.
Potass. Chlorate	3d.—4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	[illegible]3 10s. per ton d/d.
Soda Caustic, solid	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to [illegible]gth. 20s. less for contracts.
Soda Crystals	[illegible]—£5 10s. per ton ex railway [illegible]ots or ports.
Sod. Acetate 97/98[illegible]	[illegible] per ton.
Sod. Bicarbonate	£10 10s. per ton, carr. paid.
Sod. Bichromate	4½d. per lb.
Sod. Bisulphite Powder 60/62%	£17—£18 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96%	£1[illegible] [illegible]s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. 60/65	About £[illegible] 10s. per ton d/d.
Sod. Sulphide cryst.	£9 per ton d/d.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	6½d.—1s. 2d. per lb., according to quality.
Crimson	1s. 4d.—1s. 6d. per lb., according to quality.
Arsenic, Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide	£30—£33 per ton, according to quantity.
Carbon Black	7d.—7½d. per lb. ex wharf.
Carbon Tetrachloride	£60—£65 per ton, according to quantity, drums extra.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes White and Dark	5d.—9½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	£48 per ton, barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£16 5s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Precip. B.P.	£47 10s.—£52 10s. per ton, according to quantity.
Sulphur Chloride	4d. per lb., carboys extra.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep	5s. 1d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

There is a general feeling that the fall in price of acetates during the last few weeks has reached its limit. The tendency is now to stiffen again.

Acetate of Lime—	
Brown	£11 10s. per ton, and upwards.
Grey	£14 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Demand quiet but price steady.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 9d. per gall. Unrefined.
Wood Naphtha—	
Miscible	4s. 9d. per gall. 60% O.P.
Solvent	5s. per gall. 40% O.P. Firmer.
Wood Tar	£4—£5 per ton. Very quiet.
Brown Sugar of Lead	£41 per ton. Steady market.

TAR PRODUCTS

Acid Carbolic—	
Crystals	6½d. per lb. Quiet.
Crude 60's	1s. 8d.—1s. 10d. per gall. Market flat.
Acid Cresylic, 97/99	2s.—2s. 1d. per gall. Demand steady.
Pale 95%	1s. 8d.—2s. per gall. Not much enquiry.
Dark	1s. 8d.—1s. 10d. per gall. Market dull.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	6½d.—7½d. per gall. Small demand
Unstrained	6d.—6½d. per gall.

Benzole—
Crude 65's .. .. 7½d.—9d. per gall. ex works in tank wagons.
Standard Motor .. 1s. 1½d.—1s. 3d. per gall. ex works in tank wagons.
Pure .. .. .. 1s. 5½d.—1s. 7d. per gall. ex works in tank wagons.

Toluole—90% .. .. 1s. 5d.—1s. 6d. per gall. More inquiry.
Pure .. .. 1s. 7d.—1s. 9d. per gall. Small demand for home consumption.

Xylol—Coml. .. .. 2s. 3d. per gall.
Pure .. .. 3s. 3d. per gall.

Creosote—
Cresylic 20/24% .. 8d.—8½d. per gall. Little demand.
Middle Oil .. .. }
Heavy Oil .. .. }
Standard Specification } 5½d.—6½d. per gall., according to quality and district. Fair business passing. A little more demand for export in bulk.

Naphtha—
Solvent 90/160 .. 1s. 3d.—1s. 4d. per gall. Demand good.
Solvent 90/190 .. 11d—1s. per gall. Fair inquiry. Local demand good.

Naphthalene Crude—
Cheaper in Yorkshire than Lancashire. Demand rather better.
Drained Creosote Salts £3—£5 per ton. Demand slightly better.
Whizzed or hot pressed £6—£9 per ton. Demand very poor.

Naphthalene—
Crystals and Flaked .. £12—£15 per ton, according to district.

Pitch, medium soft .. 42s. 6d.—60s. per ton according to district. Plenty of inquiry. Prospects brighter.

Pyridine—90/160 .. 19s. per gall. Steady demand.
Heavy .. 11s.—12s. per gall. Market dull.

INTERMEDIATES AND DYES

Business in dyestuffs has been very well maintained this week.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 7d. per lb.
Acid H. .. .. .. 3s. 11d. per lb. 100% basis d/d.
Acid Naphthionic .. 2s. 2d. per lb. 100% basis d/d.
Acid Neville and Winther 5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech. .. 1s. 1d. per lb. Improved demand.
Acid Sulphanilic .. 9d. per lb. 100% basis d/d.
AluminiumChloride,anhyd. 1s. per lb. d/d.
Aniline Oil .. .. 8d. per lb. naked at works.
Aniline Salts .. .. 8½d. per lb., naked at works.
Antimony Pentachloride 1s. per lb. d/d.
Benzidine Base .. .. 3s. 11d. per lb. 100% basis d/d.
Benzyl Chloride 95% .. 1s. 1d. per lb.
p-Chlorphenol .. .. 4s. 3d. per lb. d/d.
p-Chloraniline .. .. 3s. per lb. 100% basis.
o-Cresol 19/31° C. .. 4d.—4½d. per lb. Rather quiet.
m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline .. .. 3s. per lb.
Dichloraniline S. Acid .. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol .. .. £85 per ton.
Diethylaniline .. .. 4s. 3d. per lb. d/d., packages extra, returnable.
Dimethylaniline .. .. 2s. 2½d. per lb. d/d. Drums extra.
G. Salt. .. .. .. 2s. 4d. per lb. 100% basis d/d.
a-Naphthol .. .. 2s. 5d. per lb. d/d.
Dinitrobenzene .. .. 9d.—10d. per lb. naked at works.
Dinitrochlorbenzol .. £84 10s. per ton d/d.
Dinitrotoluene—48/50° C. 8d.—9d. per lb. naked at works.
66/68° C. 1s. 2d. per lb. naked at works.
Diphenylamine .. .. 2s. 10d. per lb. d/d.
Monochlorbenzol.. .. £63 per ton.
β-Naphthol .. .. 1s. per lb. d/d.
a-Naphthylamine .. 1s. 3½d. per lb. d/d.
β-Naphthylamine .. 4s. per lb. d/d.
m-Nitraniline .. .. 4s. 2½d. per lb. d/d.
p-Nitraniline .. .. 2s. 2½d. per lb. d/d.
Nitrobenzene .. .. 5½d.—5¾d. per lb. naked at works.
o-Nitrochlorbenzol .. 2s. 11d. per lb. 100% basis d/d.
Nitronaphthalene .. 10½d. per lb. d/d.
p-Nitrophenol .. .. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol 4s. 6d. per lb. 100% basis.
m-Phenylene Diamine .. 3s. 10d. per lb. d/d.
p-Phenylene Diamine .. 10s. 2d. per lb. 100% basis d/d.
R. Salt .. .. .. 2s. 4d. per lb. 100% basis d/d.
Sodium Naphthionate .. 2s. 2d. per lb. 100% basis d/d.
o-Toluidine .. .. 10d. per lb.
p-Toluidine .. .. 3s. per lb. naked at works.
m-Toluylene Diamine .. 3s. 10d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P. .. £43—£45 per ton, ex wharf London, in glass containers.
Acid, Acetyl Salicylic .. 3s. 1d.—3s. 3d. per lb., according to quantity. Sales steady. Price firm.
Acid, Benzoic B.P. .. 2s. 6d. per lb. Cheaper.
Acid Boric B.P. .. .. Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric.. .. 19s.—21s. per lb.
Acid, Citric .. .. 1s. 4d. per lb., less 5% for ton lots. Market still weak.
Acid, Gallic .. .. 2s. 9d. per lb. for pure crystal in 2 cwt. lots.
Acid, Pyrogallic, Cryst. .. 6s. 9d. per lb. Resublimed quality 8s. per lb. Market firm.
Acid Salicylic .. .. 1s. 6d.—1s. 8d. per lb., according to quantity. Slightly firmer.
Acid, Tannic B.P. .. 2s. 10d. per lb. Forward quotations higher spot value likely to increase.
Acid, Tartaric .. .. 1s. per lb., less 5%.
Amidol .. .. .. 9s. per lb. d/d.
Acetanilide .. .. 2s. per lb. for quantity. More enquiry.
Amidopyrin .. .. 15s. per lb.
Ammon. Benzoate .. 3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P. £37 per ton.
Atropine Sulphate .. 12s. 6d. per oz. for English make.
Barbitone.. .. .. 13s. 9d. per lb. Slightly lower. Quiet steady demand.
Benzonaphthol .. .. 5s. 3d. per lb. spot.
Bismuth Carbonate .. 10s. 6d.—12s. 6d. per lb.
„ Citrate.. .. 10s. 3d.—12s. 3d. „
„ Salicylate .. 9s.—11s. „
„ Subnitrate .. 8s. 8d.—10s. 8d. „
Borax B.P. .. .. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides .. .. .. Market exceedingly firm and prices advancing. Raw materials dearer. British prices lower than foreign.
Ammonium .. .. 1s. 11d. per lb.
Potassium .. .. 1s. 9d. per lb.
Sodium .. .. .. 1s. 10d. per lb.
Calcium Lactate .. .. 1s. 7d.—2s. per lb., according to quantity. Fair demand and steady market.

Chloral Hydrate	4s. per lb. Slightly easier.
Chloroform	2s. 6d. per lb. for cwt. lots. Price advanced by 6d. per lb.
Formaldehyde	£48—£49 per ton in barrels, ex wharf London.
Glycerophosphates— Calcium, soluble and citrate free	Fair business passing. 7s. per lb.
Glycerophosphates—	
Iron	8s. 9d. per lb.
Magnesium	9s. per lb.
Potassium, 50% ..	3s. 6d. per lb.
Sodium, 50%	2s. 6d. ,,
Guaiacol Carbonate ..	10s. per lb.
Hexamine	3s. per lb. Forward prices higher.
Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor ..	English make offered, 120s. per oz.
Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. ,,
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb.
Magnesium Carbonate— Light Commercial ..	£36 per ton net.
Magnesium Oxide—	
Light Commercial ..	£75 per ton, less 2½%.
Heavy Commercial ..	£25 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst, B.P. ..	62s. 6d. per lb. Market much firmer.
Synthetic	26s.—35s. per lb., according to quantity. English make. Increasing demand.
Mercurials	Market very quiet.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate ..	3s. 6d.—3s. 7d. ,,
White precip.	4s. 7d.—4s. 8d. ,,
Calomel	3s. 11d.—4s. ,,
Methyl Salicylate ..	1s. 9d.—2s. per lb. Seasonal increase in demand.
Methyl Sulphonal ..	24s. per lb. Slightly weaker.
Metol	11s. per lb. British make.
Paraformaldehyde ..	2s. 8d. per lb. for B.P. quality.
Paraldehyde	1s. 4½d.—1s. 6d. per lb. in free bottles and cases. Supplies plentiful.
Phenacetin	5s. 8d. per lb.
Phenazone	6s. 10d. per lb.
Phenolphthalein	5s. 9d. per lb. Supply exceeds demand.
Potass. Bitartrate— 99/100% (Cream of Tartar)	84s. per cwt., less 2½% for ton lots.
Potass. Citrate	1s. 10d.—2s. 2d. per lb.
Potass. Ferricyanide ..	1s. 9d. per lb. Quiet.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Steady market.
Potass. Metabisulphite ..	7½d. per lb., 1-cwt. kegs included. F.o.r. London.
Potass. Permanganate ..	7½d. per lb. spot. Forward prices higher.
Quinine Sulphate ..	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. 6d. per lb.
Saccharin	63s. per lb., in 50-lb. lots.
Salol	3s. 9d. per lb. for cwt. lots.
Silver Proteinate	9s. per lb. for satisfactory product, light in colour.
Sod. Benzoate, B.P. ..	2s. 6d. per lb. Supplies of good quality now available.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite— Photographic	£13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside ..	16s. per lb.
Sod. Potass. Tartrate (Rochelle Salt) ..	75s.—82s. 6d. per cwt., according to quantity. Quiet market.
Sod. Salicylate	Fair demand. Powder 2s.—2s. 3d. per lb. Crystal at 2s. 2d.—2s. 5d. per lb. Flake 2s. 6d. per lb.
Sod. Sulphide— Pure recryst.	10d.—1s. 2d. per lb.
Sod. Sulphite, anhydrous	£27 10s. per ton, minimum 5-ton lots, increasing according to quantity, 1-cwt. kegs included.
Sulphonal	15s. 6d. per lb. Little demand.
Thymol	16s. per lb.

PERFUMERY CHEMICALS

Acetophenone	12s. per lb.	
Aubepine	15s. 3d. ,,	
Amyl Acetate	2s. 9d. ,,	
Amyl Butyrate	6s. 9d. ,,	
Amyl Salicylate	3s. 3d. ,,	
Anethol (M.P. 21/22° C.)	4s. 6d. ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 9d. ,,	
Benzyl Alcohol free from Chlorine	2s. 9d. ,,	
Benzaldehyde free from Chlorine	3s. 6d. ,,	
Benzyl Benzoate	3s. 6d. ,,	
Cinnamic Aldehyde— Natural	18s. 9d. ,,	
Coumarin	19s. 6d. ,,	
Citronellol	17s. ,,	
Citral	8s. ,,	
Ethyl Cinnamate ..	12s. 6d. ,,	
Ethyl Phthalate	3s. 3d. ,,	
Eugenol	10s. ,,	
Geraniol (Palmarosa) ..	33s. 6d. ,,	
Geraniol	11s. 6d.—18s. 6d. per lb.	
Heliotropine	6s. 9d. ,,	
Iso Eugenol	16s. ,,	Dearer.
Linalol ex Bois de Rose ..	26s. ,,	
Linalyl Acetate	26s. ,,	
Methyl Anthranilate ..	9s. 6d. ,,	
Methyl Benzoate	5s. ,,	
Musk Ambrette	50s. ,,	
Musk Xylol	13s. 6d. ,,	
Nerolin	4s. 9d. ,,	
Phenyl Ethyl Acetate ..	15s. ,,	
Phenyl Ethyl Alcohol ..	16s. ,,	
Rhodinol	55s. ,,	
Safrol	1s. 10d. ,,	
Terpineol	2s. 4d. ,,	
Vanillin	25s. 6d. ,,	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.	
Anise Oil	2s. 10d. per lb.	Dearer.
Bergamot Oil	16s. 6d. per lb.	
Bourbon Geranium Oil ..	33s. 6d. per lb.	
Camphor Oil	65s. per cwt.	
Cananga Oil Java ..	10s. per lb.	

Cassia Oil, 80/85%	.. 10s. per lb.	
Cinnamon Oil, Leaf	.. 6½d. per oz.	
Citronella Oil—		
Java 85/90% ..	.. 6s. 10½d. „	Again dearer.
Ceylon	.. 3s. 8d. per lb.	Dearer.
Clove Oil	.. 8s. per lb.	Dearer.
Eucalyptus Oil 70/75%..	2s. 3d. per lb.	
Lavender Oil—		
French 38/40% Esters	32s. 6d. per lb.	
Lemon Oil ..	.. 3s. 2d. per lb.	
Lemongrass Oil ..	.. 4s. 6d. per lb.	
Orange Oil, Sweet	.. 11s. per lb.	
Otto of Rose Oil—		
Bulgarian ..	.. 40s. per oz.	
Anatolian ..	.. 18s. per oz.	
Palma Rosa Oil ..	... 16s. 6d. per lb.	
Peppermint Oil—		
English.. ..	.. 70s. per lb.	
Petitgrain Oil ..	.. 9s. 6d. per lb.	Dearer.
Sandal Wood Oil—		
Mysore	.. 26s. 7d. per lb.	
Australian ..	.. 18s. 6d. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before Dec. 29th; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on Nov. 13th.

I.—Applications

Campbell. Filters or separators. 25,407. Oct. 25.

Craig, and Spence and Sons. 25,096. *See* VII.

Dickinson. Grinding-machine. 25,304. Oct. 24.

Jackson. Apparatus for straining liquids. 25,342. Oct. 24.

Kelly. Acid-proof etc. containers. 25,271. Oct. 23.

Morris. Pulverising or emulsifying apparatus. 24,875. Oct. 20.

Portham. Centrifugal separators etc. 25,365. Oct. 24.

Silica Gel Corporation. Refrigeration. 25,444. Oct. 25. (U.S., 20.11.23.)

Soc. Beaudrey et Bergeron. Filters. 25,453. Oct. 25. (Fr., 29.11.23.)

Soc. des Appareils Mangondeaux. 25,455. *See* V.

Soc. l'Air Liquide, Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude. Separation by liquefaction of complex gaseous mixtures. 25,028. Oct. 21. (Fr., 7.8.24.)

Soc. l'Auxiliaire des Chemins de Fer et de l'Industrie. Pumps for liquids at high temperature. 25,282. Oct. 23. (Fr., 3.11.23.)

Spencer, Chapman and Messel, Ltd., and Liebert. Manufacture and manipulation of colloidal substances etc. 24,902. Oct. 20.

I.—Complete Specifications Accepted

16,155 and 16,156 (1923). Peale and Peale. Separating materials of different specific gravities. (223,279 and 223,280.)

20,286 (1923). Forns, Stapley, and Harrison. Adjustable centrifugal machine for emulsifying. (223,347.)

II.—Applications

Clemm, Schmidt and Ges. f. Chem. Produktion. Process for making highly-active charcoal in grains. 25,138. Oct. 22.

Duffield. Production of gas from powdered carbonaceous matter. 25,071. Oct. 21.

Kraitschier. Fuels for internal-combustion engines. 24,880. Oct. 20. (Ger., 18.10.23.)

Malbay. Semi-water-gas producer plants. 24,933. Oct. 20. (Fr., 9.11.23.)

Michalski. Converting coal into gas. 24,929. Oct. 20. (Ger., 17.12.23.)

Roux. Treatment of peat etc. 25,425. Oct. 25. (Fr., 26.10.23.)

Shearman. Destructive distillation of bones etc. 25,338. Oct. 24.

Soc. des Appareils Magondeaux. 25,455. *See* V.

Soc. l'Air Liquide, Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude. Production of coke. 24,925. Oct. 20. (Fr., 6.7.24.)

Soc. l'Air Liquide, Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude. 25,299. *See* VII.

Spencer. Gas purifiers. 25,098. Oct. 22.

II.—Complete Specifications Accepted

18,412 (1923). Electrical Improvements, Ltd., and Weeks. Fuel distillation. (223,297.)

18,461 (1923). Laing and Nielsen. Heat treatment of solid carbonaceous materials, and the manufacture of briquettes. (223,302.)

18,580 (1923). British Thomson-Houston Co., Ltd. *See* XI.

20,082 (1923). Curtiss. Fuel for the firing of bricks and other purposes. (223,345.)

21,492 (1923). Lamplough and Lamplough. Production of explosive or combustible gaseous-mixtures. (223,356.)

23,036 (1923). Stowart. *See* XXIII.

24,632 (1923). Merz and McLellan and Weeks. Low-temperature fuel distillation. (223,387.)

5756 (1924). Govan. Bituminous solution. (223,486.)

6017 (1924). L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude. Treatment of illuminating or coke-oven gases and the like prior to partial liquefaction for the separation of their constituents. (223,489.)

7979 (1924). Brun. Manufacture of fuel briquettes. (214,229.)

III.—Applications

Cox and McDermott. Purification of benzol etc. 25,038. Oct. 21.

Jackson (Warren). 25,160. *See* IX.

IV.—Applications

British Dyestuffs Corporation, Ltd., and Saunders. Manufacture of intermediate compounds and azo dyestuffs. 25,069. Oct. 21.

British Dyestuffs Corporation, Ltd., Goodwin and Saunders. Manufacture of azo dyes. 25,152. Oct. 22.

Scottish Dyes, Ltd., Thomas, and Thompson. Manufacture of dyestuffs etc. 25,033. Oct. 21.

Soc. of Chemical Industry in Basle. Manufacture of condensation products of the anthraquinone series. 24,954. Oct. 20. (Switz., 26.10.23.)

IV.—Complete Specifications Accepted

29,730 (1923). Kalle and Co. Akt.-Ges. Production of vat colouring-matters. (207,553.)

5441 (1924). Durand and Huguenin Akt.-Ges. Manufacture of new mordant dyestuffs. (223,481.)

V.—Applications

Cuprum Soc. Anon. Apparatus for spinning artificial silk. 25,469. Oct. 25. (Switz., 26.11.23.)

Dreyfus. Manufacture of cellulosic products. 25,462, 25,463. Oct. 25.

Grewin. Manufacture of paper. 25,367. Oct. 24. (Sweden, 24.10.23.)

Heys and St. Anne's Board Mill Co. Apparatus for removing liquids from paper pulp etc. 25,289. Oct. 23.

Jackson (Severn Mills Co.). Treating wool. 24,922. Oct. 20.

Langwell. 25,275. *See* XVIII.

Oberlander. Manufacture of artificial silk. 25,060. Oct. 21.

Soc. des Appareils Magondeaux. Manufacture of granular cellulose and its application for storage of explosive gases etc. 25,455. Oct. 25. (Fr., 20.11.23.)

V.—Complete Specification Accepted

23,240 (1923). Vereinigte Glanzstoff-Fabriken Akt.-Ges. Working-up cellulose sludge. (204,322.)

VI.—Application

Lumb (Gerdner). Dyeing-machines. 25,330. Oct. 24.

VI.—Complete Specifications Accepted

21,078 (1923). Soc. of Chemical Industry in Basle. Process for producing fast tints on the fibre. (202,984.)

11,655 (1924). Brunner, Mond and Co., Ltd. Process of making ammonia by catalysis. (215,789.)

VII.—Applications

Bredig and Elod. Production of hydrocyanic acid. 25,160. Oct. 22.

Craig and Spence and Sons. Treatment of aluminous materials for filtering etc. media. 25,096. Oct. 22.

Deutsche Gold- und Silber-Scheideanstalt vorm. Roessler. Manufacture of hydrogen cyanide. 25,147. Oct. 22.

Fabrique Nationale de Produits Chimiques et d'Explosifs-Anciens Etablissements Ghinigoult et Delattre Soc. Anon. Manufacture of ammonia and ammonia compounds from cyanamides. 25,148. Oct. 22. (Belgium, 23.10.23.)

Harper and Williams. Production of ammonia. 25,264. Oct. 23.

Johnson (Viscose Co.). Apparatus for separating caustic hydroxides from solutions etc. 25,290. Oct. 23.

Neill. Production of ferric oxide etc. 25,382. Oct. 24.

Soc. des Mines de Potasse d'Alsace, Amélie, Max, Joseph, Else, Théodore, Prince Eugène, Fernand (Autrefois Reichsland), Anna, Marie, et Marie-Louise. Manufacture of magnesium sulphate. 25,424. Oct. 25. (Fr., 29.10.23.)

Soc. l'Air Liquide, Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude. Extraction of hydrogen from gaseous mixtures. 25,299. Oct. 23. (Fr., 8.3.24.)

VII.—Complete Specifications Accepted

15,237 (1923). Marks (Cobb Electro Reduction Corporation of Canada, Ltd.). *See* X.

19,735 (1923). "Allchemin" Aligem. Chem. Industrie Akt.-Ges., and Jahoda. Production of phosphorescent zinc sulphide. (201,922.)

1189 (1924). Seth. *See* X.

IX.—Applications

Airey. Manufacture and use of building etc. materials. 24,973, 25,199. Oct. 21 and 23.

Burley. Manufacture of cement and kilns therefor. 25,171. Oct. 22.

Jackson (Warren). Manufacture of bituminous compositions. 25,160. Oct. 22.

Rigby. Manufacture of cement. 25,162. Oct. 22.

IX.—Complete Specification Accepted

20,082 (1923). Curties. *See* II.

X.—Applications

Burgess and Vautin. Ferro alloys. 25,383. Oct. 24.

Kidd. Furnaces for heat treatment of metals. 24,995. Oct. 21.

Marks (Glockenstahlwerke Akt.-Ges. vorm. R. Lindenberg). Steel alloy for permanent magnets. 25,280. Oct. 23.

X.—Complete Specifications Accepted

15,237 (1923). Marks (Cobb Electro Reduction Corporation of Canada, Ltd.). Volatilising and oxidising minerals. (223,271.)

1189 (1924). Seth. Process for obtaining vanadium compounds or vanadium from pig-iron containing vanadium. (211,111.)

2857 (1924). Cornelius. Electric furnace for welding, tempering, burning, or for heating for other purposes. (211,462.)

XI.—Applications

Darby, Wilde, and Oldham, and Son. Galvanic batteries. 24,941. Oct. 20.

Electric Furnace Co., Ltd., and Taylor. Electric resistance furnaces.

Kahl and Rutgerswerke A.-G. Impregnating medium for electrodes. 24,946. Oct. 20.

XI.—Complete Specifications Accepted

18,580 (1923). British Thomson-Houston Co., Ltd. Electrodes having a high-electron emissivity. (201,900.)

2857 (1924). Cornelius. *See* X.

XII.—Applications

McNicoll. Treatment of crude cotton oils etc. 25,319. Oct. 24.

Shearman. Refining fats, oils, etc. 25,337. Oct. 24.

Sizer. Extraction of oil from seeds etc. 25,200. Oct. 23.

Sizer. Extraction of oil from oil-bearing substances. 25,421. Oct. 25.

XIII.—Application

Lorenz. Manufacture of wax-colour binding-means. 25,049. Oct. 21. (Austria, 23.11.23.)

XIII.—Complete Specification Accepted

17,663 (1923). Soc. Italiana E. de Angoli per l'Industrie dei Tessuti Stampati and Paulus. Manufacture of aqueous solutions from difficultly-soluble gums. (200,523.)

XIV.—Applications

Rigby. Rubber latex compositions, and application thereof. 24,970. Oct. 21.

Soc. Anon. des Pneumatiques Dunlop. Vulcanisation of rubber in solution. 25,400. Oct. 25. (Fr., 19.7.24.)

XIV.—Complete Specifications Accepted

12,964 (1923). Loomis and Stump. Manufacture of rubber goods from latex. (223,263.)

4069 (1924). K. D. P., Ltd. Manufacture of caoutchouc, gutta-percha, balata, and analogous vegetable resins. (219,277.)

XVIII.—Application

Langwell. Fermentation of cellulose materials. 25,275. Oct. 23.

XIX.—Applications

Fairbrother (Jackson Research Corporation). Disposing of municipal waste. 25,295. Oct. 23.

Hartley. Sewage purification. 24,868. Oct. 20.

Hind. Production of foodstuffs. 25,373. Oct. 24.

XIX.—Complete Specification Accepted

4505 (1923). Townsend and Lever Bros., Ltd. Treating pea-nuts for food. (222,975.)

XX.—Complete Specifications Accepted

20,425 (1923). Chemosan Akt.-Ges. Process for the production of solutions of mercury derivatives of hydroxy-sulphobenzoic acids and their homologues, suitable for use in therapeutics. (202,631.)

27,463 (1923). British Dyestuffs Corporation, Ltd., Cronshaw, Naunton and Green. Manufacture of diarylguanidines. (223,410.)

XXIII.—Complete Specification Accepted

23,036 (1923). Stewart. Regulating the gas flow to gas calorimeters. (223,375.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1), has received the following enquiries for British Goods. British firms may obtain further information by applying to the Department and quoting the specific reference number: *Belgium:* Paper, (463); *Brazil:* Steel, tinplate, zinc, cement, red lead, copper sulphate, (476); *Egypt:* Leather, (Inspecting Engineer, Egyptian and Sudan Governments, Queen Anne's Chambers, London, S.W. 1, Ref. Muh. 1924/64/6); *France:* Steel, (464); *Italy:* Leather, (467); *Lithuania:* Pig iron, (A.X./1420); *New Zealand:* Hardware, (458); *Sweden:* Leathers, (471).

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council of Pure and Applied Chemistry

which consists of Representatives from

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals and the Royal Agricultural Society.

VOL. 43 NEW SERIES | LONDON, NOVEMBER 14, 1924 | No. 46

EDITORIAL

THERE is a possibility that next summer we may receive a visit from some American engineers. There are big industrial cities in America and there are others here. It will be impossible for our visitors to avoid making a comparison, and the prospect of this is not particularly pleasing. We can show a[illegible] visitors—especially Americans—London, Edinburgh, Oxford, Cambridge, York and Canterbury with justifiable satisfaction. But our manufacturing towns—what do we think of them? What will they think of them? You may travel from King's Cross through York and Edinburgh to Inverness or even further, and are almost the whole time in pleasant and clean country, much of it beautiful country, but we can mention cities, even districts, in the Midlands, in Yorkshire and Lancashire and in Scotland, of which we are now, and for some time shall be, ashamed. They are mean and dirty; they have fine buildings, beautiful parks and other advantages, but they are begrimed with smoke. Who can be surprised that many of these districts return Socialists to Parliament? We think if we lived in them ourselves we should be as desperate as any of the most obstreperous of the Communists. Wigan, St. Helens, Glasgow and Leeds are not places of beauty. They might, though, be cleaner than they are. There is a Smoke Abatement Society, a League, a Conference, a set of pamphlets describing the ways of estimating the quantity and quality of smoke and of preventing or diminishing it. The problem is not insoluble; it is largely a matter of chemical engineering, and in essential matters it has already been solved. There are two sources of smoke almost equally important and obnoxious—house fires and works fires. We can solve the first difficulty quite easily; in our own domestic arrangements we have so organised things that we can sit in front of a smokeless fire, enjoy its warmth and life, stir it and look at it. Everyone else can do this if a trifling effort be made; is the effort worth while? Is it not worth some little effort to secure an ampler ether, a diviner air, clearer skies, cleaner houses and cleaner gardens? The smoke which arises from domestic houses is a nuisance for which we as individuals are largely responsible; we have the remedy in our own hands. The smoke from works, factories and furnaces is not so easily prevented, and it is not so much within the powers of each one of us. Even if we have ourselves sound ideas we have to submit them to a board of directors, to general managers and works managers, to trades unions and committees; we have to consider the views of shareholders, in fact everybody's views except those living in the vicinity of the works. But electricity and gas, pulverised fuel and briquettes, mechanical stokers and economisers come to the assistance of the manufacturer who wishes to do his duty.

* * *

In these technical details mere editors soon get out of their depth. Every traveller for a firm of makers of mechanical stokers, of asbestos packing, of piston-rings, of heat economisers or of patent boilers shows by most imposing figures and calculations how easy it is to save fifteen per cent. of your fuel and to pay for the new plant out of the economics it effects in the first year or eighteen months. Did we describe their mathematics as imposing? They will convince you that if you buy enough of their devices you will get your fuel for nothing! It is not all imposition; you must, of course, make some allowance for the exuberance of the traveller; he needs an optimistic nature, a heart of oak and triple brass, to enable him to go round from works to works. If his prophesies are distinguished by a little buoyancy and imagination, oh blame not the bard! And when he who adores thee has left but the name, do not, the moment he has gone, consign his rectangular card to the waste-paper basket. Many of these modern improvements are meritorious; some of them do really save money; some of them do really burn the fuel more completely and send less unburnt or half-burnt—which is worse—coal into the atmosphere. If the most prudent of our chemical manufacturers, the wisest of our chemical engineers and the most public-spirited of our statesmen could organise a round table conference they could frame some means of encouraging the laggards in industry to greater effort, helping the lazy ones on with a stick, if we have not forgotten the songs which in our youth adorned the university or the camp. We could name a dozen members of the Society of Chemical Industry and a dozen members of Parliament who could be of great

value in this respect, but would they come if we did call upon them? Those who dislike dirt and those who hate Bolshevism should combine their forces for a while. There are many men who object to waste and communism; all women dislike dirt; what a chance for organised effort!

* * *

Mr. Julian L. Baker's Streatfeild Memorial Lecture on "The Chemist and the Fermentation Industries" called back to us our first conception that these had any community of interest. Between thirty and forty years ago we remember a young man, destined to inherit a brewery, coming to a provincial college to learn science which would be of value to him in his business. This seemed to us, in our ignorance, a very strange proceeding. Brewing we could understand as a lucrative pursuit probably descending from father to son through several generations. The study of science we could appreciate even in those early days, but to mix up brewing and science seemed to be very singular. When we found that the young brewer was, in various laboratories, studying yeast, bacteria, alcohol and distillation, starch and sugar, there seemed to be some sense in the idea, and it was not long before we found out that a man might study these subjects for many years before getting to the end of them. We have no reason to think that the average man of to-day is much better able now, than we were so many years ago, to see how science and brewing fit in together. Such an address as Mr. Baker's helps us to see how the average man may be enlightened in such matters. Mr. Baker, besides giving an interesting account of some of the scientific aspects of brewing, calls our attention to a curious piece of red-tape which may be of importance. He tells us that our home fermentation industries yield nearly a hundred and forty million pounds a year in revenue to the State, and that the revenue authorities are extremely careful in watching the operations of the brewers and distillers and verifying in these the percentages of alcohol and sugar so that the nation may lose nothing of the proportion of the profits which it takes. In the "Amylo" process of fermentation it seems the Customs regulations and the details of the process conflict so that this process, widely used on the Continent, is forbidden here. If the process is as economical as Mr. Baker indicates, and there are no material factors omitted from his account of the situation, it appears the distillers have a just cause of complaint. If this is so we are satisfied they can obtain a reasonable amount of satisfaction if they make up their minds that they mean to have it. Governments and Government Departments are particularly susceptible to adequate pressure tactfully applied.

* * *

Mr. Baker gave an account of the Finsbury Technical College, and alluded to some of the eminent men who taught there; he made an earnest plea for a continuation of the important work still carried on there. We sincerely hope his plea will be successful, although the figures he quoted show that his task of persuading the authorities to find the necessary money will be an extraordinarily difficult one. We received a few days ago a handsome volume describing the activities of the Leeds Philosophical and Literary Society during the last hundred years with some incidental remarks on the foundation of the Yorkshire College, now the University of Leeds. The Finsbury Technical College and the Yorkshire College had much in common. Each was started at a time when there was a great demand for scientific knowledge and very little supply. The earliest professors at each of these institutions included four or five young men of more than average ability, with no hard and fast traditions, with great zeal for teaching on the best methods and with a determination to make their college a centre of good teaching and good research. At Finsbury, Profs. Armstrong, Ayrton, Meldola, Perry and some others formed a closely allied band, who successfully attained the objects they sought; at Leeds, Profs. Green, Miall, Rucker and Thorpe, with some others, formed a similar nucleus. It seems now to be less easy to find either in London or in the provinces men of the type we have in mind; the sciences have g[illegible] immensely in volume, and those who study them have become much more specialised. Prof. Green was a first-class mathematician as well as a first-class geologist. Prof. Miall could have occupied the chair of geology or zoology with equal ease. Prof. Armstrong has not confined his activities solely to chemistry. He has wandered, perhaps trespassed, over many fields. It was perhaps the novelty of science, certainly not the prospect of making a fortune, which attracted such men to professorships in new colleges. Science is no longer so novel as it was fifty years ago. We can well remember the time in Leeds when the classes which each professor taught were very small, a mere handful of men, but all anxious to learn. We feel sure it was the same at Finsbury. There was a great opportunity, and both the colleges we have in mind seized it and made the most of it. That sort of opportunity and that sort of man have probably become extinct in this country. Chemistry is as well established and as well known as mathematics, perhaps even more. Classes in chemistry are huge. The small nucleus of half-a-dozen enthusiasts working together to start a centre of scientific education, overcoming gradually their own obstacles of education and organisation, has been replaced by a much larger body of equally able and learned men with more time taken up by routine and by teaching and with less time available for doing pioneer work. It is a pity in some respects that the old order has passed away. On the other hand, the haphazard and scanty scientific education of fifty years ago has been replaced by a widespread and generous system of education so well organised that in every town in this country are opportunities for a thorough scientific education which were unknown when Finsbury was started. No one can fail to notice the improvement, no one can fail to regret the disappearance of some of the singularly efficient colleges which half a century ago, though few in numbers, included some which were marvels of sensible teaching and accurate research. Finsbury was one of these.

THE SMOKE ABATEMENT CONFERENCE

The conference and exhibition organised by the Smoke Abatement League in Manchester were opened on November 4 by the Lord Mayor of Manchester, who said that no single factor impaired the amenities of a city more than black smoke. The Manchester Air Pollution Advisory Committee estimated, on a conservative basis, that the damage due to smoke in that city amounted to a million pounds annually. There were two lines of action. Legislation was necessary, but education was more important, as public opinion still needed to be aroused. Mr. C. Elliott gave an account of the difficulties under which the League was working, and rew attention to the need for financial support from ocal authorities. Next year it was hoped to arrange an international exhibition and conference.

Legislation

The opening session was devoted to the legislative aspects of the smoke problem, the first paper being by Mr. J. W. Graham, the chairman of the Smoke Abatement League. In his paper Mr. Graham discussed the law against smoke and showed the difficulties of applying the Public Health Act of 1875. In practice the legislation against smoke was a dead letter, except in London, and about seven provincial towns. It was impossible to legislate effectively against smoke, as the use of gas and electricity could not yet be made compulsory and universal. When low-temperature carbonisation had been established, legislation against all use of raw coal might become practicable and reasonable. In describing the recent attempts at legislation, Mr. Graham said the Departmental Committee that examined the question was so impressed by statements that smoke-making was essential to manufacture in Sheffield and the Potteries that the crucial point of making smoke emission a definite offence was abandoned. Instead of amendments to previous legislation, there should be a new Bill, of which the principal clause should make smoke emission a nuisance. Means of transport should be included, the local authorities, now ineffective, should be concentrated, and there should be more technical inspectors. It was impossible to abolish all smoke, but a suspicion of smoke in the atmosphere would do no harm. The rest of the paper was devoted to an account of means employed to abate smoke in the United States.

In the discussion Mr. C. E. Stromeyer said there was not much smoke in Manchester; the climate was to blame. Invisible smoke was far more injurious than visible black smoke. Dr. J. S. Owens later exhibited a slide, made that day, showing the smoke present in Manchester air.

The possibilities of smoke prevention under the Public Health Act, 1875, were considered by Mr. R. M. Rowe, who said that the manufacturing contribution to smoke could be dealt with at once; he hoped that pollution due to domestic smoke would be prevented as soon as possible. Mr. Rowe then gave an informative account of the powers given in the 1875 Act, and said that if the law were applied a great improvement would result.

At the second session, Dr. J. S. Owens discussed "Air Pollution," and observed that although a human being consumed 30 lb. of air daily and only 7 or 8 lb. of food and water, no attention was paid to the purity of air, in contrast with the severe control of the purity of food. Tables were given to show the extent of pollution in several districts, the deposit of impurity per sq. mile during the year ended March 31, 1924, ranging from 100·92 tons at Rothamsted to 413·6 t. at Salford, and 793·9 t. at Rochdale. The particles in the smoke were excessively small, but this might increase their harmful effect Dr. J. R. Ashworth, of Rochdale, exhibited diagrams of measurements of the atmospheric pollution in a Lancashire town, and said that the ratio of factory smoke to household smoke varied, but that it would be at least 50 per cent. in a town like Rochdale.

Sir Frank Baines, director of H.M. Office of Works, spoke at the evening conference on the effect of atmospheric impurities on buildings. He said that his department spent £1,570,000 a year in looking after Government buildings, and he estimated that from 30 to 40 per cent. of this expenditure would be saved if only we had a pure, acid-free atmosphere. Prof. J. B. Cohen, F.R.S., followed with an address on the work of the Departmental Committee on Smoke Abatement, and showed slides illustrating the damage done to plants by smoke. He had found, after careful experiments, that the amount of impurity emitted by domestic smoke was 6 per cent. of the coal burned. The Fuel Research Board was the proper authority to take up the question.

Low-temperature Carbonisation

On November 5 a morning visit was paid to the Bradford Road gasworks of the Manchester Corporation. The subject of the session which followed the visit was "Low-temperature Carbonisation and Smokeless Fuel."

Mr. R. Maclaurin described the Maclaurin smokeless fuel plant which is being erected for the Corporation of Glasgow by Blair, Campbell and McLean, Ltd. Low-coking coal with a small ash content and from 25 to 40 per cent. of volatile matter was preferred. The producer unit was 36 ft. high and shaped like a blast furnace, air ports being provided midway up in a central wall and in the side walls. In starting up, the producer was filled up to a little above the air port with ashes, and wood was inserted through special doors and ignited. When properly ignited the producer was filled with coke, the air blast being in action all the time. When the heat had travelled well up the charge, sufficient ash was discharged to admit a ton of coal, and every successive hour a discharge was made and a ton of coal admitted. After 25 to 30 hours the first coke made would be withdrawn, the coal having been heated from 15° C. through 700° C. in 20 hours, so that the hourly rise in temperature was about 35° C. This

gradual increase in temperature modified the nature of the coke, which was very different from ordinary gas coke. The coke was hardly a low-temperature coke, but its content of volatile matter had been reduced to 3 or 4 per cent., and it ignited readily (on account of its porosity) if the temperature had not been too high. Higher temperatures gave a silvery grey, harder coke, which was not so easy to ignite, though showing little difference in composition from the previous type. The quantity of gas made regulated the type of coke produced; with a make of 25,000 to 30,000 cb. ft., black smokeless fuel was obtained, the grey type being produced with gas yields of over 30,000 cb. ft. With Scotch coals (6—10 per cent. moisture, 30—35 per cent. volatile matter), about 55 per cent. of smokeless fuel had been obtained. The make of gas per ton of coal was guaranteed to be not less than 25,000 cb. ft. with an average calorific value of 240 B.Th.U. Before withdrawing the coke it was cooled by blowing in steam, which gave water gas on approaching the combustion zone. Producer gas was made in the combustion zone, and this gas, passing upwards, supplied the heat for carbonisation. Above the combustion zone there was a zone with a temperature between 500°—700° C., and here some ammonia was generated. Higher still was the distillation zone, where oil and gas were produced. The oils passed upwards through fuel at gradually decreasing temperatures, so that there was little decomposition and a highly phenolic crude oil was obtained, which contained paraffin and paraffin wax, olefines, some aromatic compounds, basic bodies and phenols, but no benzene, naphthalene or anthracene and little or no petrol. The oil that condensed in the cool upper region was caught in a trap, whence it passed to the gas main. The gas, passing through the cold fuel, was cooled down to 70° C., so that little heat was lost. The ammonia, of which the yield was 17 to 30 lb., contained no ferrocyanides or sulphocyanides, but a considerable proportion of polyhydric alcohols, which gave rise to useful pigments. The coke was divided into three sizes and discharged into bunkers. The gas will be used for heating vertical retorts. Duplicate plant was provided, wherever possible, to avoid any chance of stoppage. With coal at 20s. and other charges at 8·3, the total working charges were 28s. 3d., a figure which could be realised by sale of the products.

Some new aspects of low-temperature distillation were discussed by Mr. H. Nielsen, M.I.Chem.E., who, starting from the standpoint that low-temperature distillation was a business proposition, outlined the position of the process. No one knew the true value of low-temperature distillation oils, and it was doubtful if the recovery of the ammonia would pay, but the gas would form a source of revenue. The production cost would decide the economic success of the process, and this cost would depend on the locality; but it could be stated that the over-all and capital costs should not exceed 4s. and 10s. to 12s., respectively, per ton of raw material treated. Owing to the fact that existing assay methods did not give results comparable with those of large-scale operations, the author had developed an assay plant which gave good agreement. After considering the difficulties of distillation, the author described the "L" and "N" process, in which a slowly rotating, inclined retort was used. The raw material passed slowly downwards to the exit, where an air-lock enabled the residue to be discharged after cooling, without allowing the entry of cold air. The hot distilling medium, the choice of which depended on local conditions, entered at the lower end of the retort in counter-current to the fuel, gradually heated the material up to the proper temperature, and escaped, carrying with it the permanent gases and condensable matters evolved by the coal. A free-burning, smokeless fuel could not be made readily from almost any raw material, and non-coking, bituminous coal would not yield a coherent residue suitable for domestic use. Blending could be accomplished, but two suitable coals were rarely found at the same colliery. Experiments had shown, however, that a preliminary heating and briquetting in the hot state without a binder, follwed by a final distillation, would give a smokeless briquette of satisfactory quality, and the process was now working on a large scale. The industrial use of coke and powdered fuel would greatly reduce the smoke nuisance, and a preliminary distillation of powdered raw coal would give a semi-coke as safe to handle as fuel oil. This would also make it feasible to erect central distillation and pulverising works to supply a standard pulverised fuel in certain areas at the same price as the raw coal. An interesting possibility was thus opened up of the use of powdered semi-coke instead of oil. The gas produced by the process would be useful for metallurgical furnaces, and if its price could be brought nearer to that of the solid fuel its use would greatly increase. To do this, we must turn to complete gasification in conjunction with low-temperature distillation, working the "L" and "N" system in a three-stage process:—(1) Gasification of the solid residue in water-gas producers; (2) distillation of the raw coal by blue water gas, the residue being converted into water gas; (3) superheating the mixed gas for use in distilling more raw coal, the solid residue forming a smokeless fuel. Ordinary water gas would thus have been "carburetted" twice with raw coal. Low-temperature distillation also made it possible to utilise sewage profitably.

The Rt. Hon. G. H. Roberts and P. C. Pope read a paper describing the "Coalite" fuel made by Low Temperature Carbonisation, Ltd. A description of the Parker process was given, and it was pointed out that the best material for low-temperature carbonisation was small coal, and this, after washing, gave a fuel that burnt well without smell or smoke. If all the coal used in Great Britain, excluding that used in gas works and coke ovens, were carbonised first at a low temperature there would be a considerable national saving. Powdered Coalite gave better results than pulverised coal, and it had an interesting future in this direction. Contracts had already been made to supply London merchants with the whole of the output of plants producing up to 3000 t. a day.

The Effect of Light on Health

The papers on "The Effect of Light on Health," by Prof. L. Hill, F.R.S., and Dr. R. V. Clark, were

pleas for the prevention of smoke pollution. It was extraordinary that the Conference was studying the question merely as an educational measure, as the effect of light on health was so obvious. Sunlight was a necessary and an efficient means of treating disease, and yet we took no precautions to ensure that we had the sunlight necessary to induce health. Many striking instances were given to show the action of light on the human organism.

Engineering Aspects of Smoke Abatement

The session on Wednesday evening was devoted to smoke abatement from the mechanical engineer's point of view, and ended in a commonly accepted assertion that a great deal might be accomplished at a cost which would be no more than the cost of efficiency with consequent profits.

Mr. T. R. Wollaston, M.I.Mech.E., in a paper on "The Complete Gasification of Coal," said there were broadly only two methods of gasifying coal: one by heating in externally-fired retorts, the other by incomplete combustion in gas producers. Every furnace was really a gas producer and many of them were very bad ones, particularly the household fire and, in a lesser degree, the normal boiler furnace. After comparing the efficiency of the gas producer with that of the boiler grate, to the disadvantage of the latter, the boiler of the future was foreshadowed as "possibly not unlike the vertical fire-tube boiler, burning coke or smokeless fuel, and with metallic wetted surface to take fierce initial temperatures." An apparatus which aimed at the elimination of certain of the limitations of ordinary gas producers had been developed. In this apparatus the fuel was first subjected to heating or coking in thin layers in an upper retort before dropping into the producer. The producer gas was thus enriched and the fuel fed to the producer was so far coked that it became readily workable. This producer would work on fuels which could not be used in other producers or for boiler firing and cost 2s. to 10s. per ton less. An annular boiler surrounded the producer, so that steam was self-generated and clinker formation prevented, there being an average gain of about 20 per cent. in thermal efficiency. There was no smoke, no appreciable waste of fuel during stand-by periods, and the boiler responded quickly to variable demands for steam. The best method of generating electricity was the indirect method with by-product recovery, as illustrated by the South Staffordshire Mond Gas Co., Ltd. Such a system, laid down on modern lines, could deliver gas to a boiler house 5 or 10 miles away, with a considerable saving. The rest of the paper described a complete smokeless programme for future power, heating and lighting.

Dr. J. T. Dunn gave a paper entitled "Powdered Fuel and the Smoke Problem," in which he first described the various systems by which pulverised fuel was prepared, the main operations in the multiple system being crushing, magnetic separation to remove iron, drying, pulverising, separation of fine from coarse material in a cyclone separator, and delivery to storage. In the unit system, each furnace was provided with a separate pulveriser which reduced the coal to the desired fineness and fed it by means of a fan directly to the burner; in unit installations drying was usually not required, and the coal was fed direct from the crusher to the pulveriser. The mechanism of the burning of ordinary coal was discussed, and it was shown that the immensely greater surface of pulverised fuel enabled it to burn almost as though it were a gas, combustion being complete with at most 10 to 15 per cent. excess of air, whereas in average mechanical stokers, 50 to 70 per cent. excess was required. Further, any change in the conditions of combustion, *e.g.*, another type of coal, could be dealt with in a few seconds. It was true that fine ash was carried up with the gases from pulverised coal, but the ash was so finely divided that it would probably be spread over an enormous area before reaching the ground. The claim that the ash constituted a nuisance had no foundation in fact, as it had been found impossible to obtain any ash so deposited for examination. The more general use of powdered fuel would mean not only a more efficient use of coal, but also approach to clearer skies.

Mr. H. G. Clinch, chief smoke inspector, Halifax, spoke on the relations between the cost of production and the smoke inspector and said that there were signs of a quickened public interest in the question of smoke abatement. He did not agree that the black smoke was emitted by any other than the factory chimney. The production of black smoke meant inefficiency, and the reason why the manufacturers needed to be spurred on to use their fuel efficiently was that they were too busy with their general business to attend to the boiler plant. Small firms were often bad in this respect, but when they were merged into a large combine, the employment of chemical engineers produced a transformation, not in the interest of public health, but solely for the cause of efficiency. The smoke inspector thus contributed to reduce costs by lowering the cost of fuel, and by reducing the obstacle to sunlight, thus reducing sickness and increasing the vigour of the population. It was admitted that black smoke could not be avoided in certain manufactures, but free discharge into the air should not be permitted any more than the pollution of rivers with trade effluents.

In a paper on "Smoke Abatement and Boiler Room Economies in Relation to the Training of Boiler Foremen," Mr. J. T. Hodgson showed the importance of the personal efficiency and intelligence of boiler firemen in producing boiler-room economies. A careful, skilled man would always make less smoke than a careless, unskilled man, even if the latter had better plant to control. Attention was drawn to the possibility of securing an abatement of smoke by educating firemen by a series of lectures, and an outline was given of subjects for a course of such lectures, ending a specimen examination paper.

Mr. W. H. Casmey read a paper on "Furnace and Tank Boiler Design," in which he claimed that a smoky chimney and a wasteful boiler could be "cured" by simple and inexpensive means, the chief of which was the adjustment of the ratio or furnace area to that of the outlets at the rear of the boiler. The data for keeping a smokeless chimney were given as follows:—Area of furnaces, twice the area of exit from furnace flues; distance from top of bridge to

crown plate, one-third diameter of furnace flue in widest part; distance from back end of boiler to brickwork, equal diameter of one furnace flue; bottom flue depth, half diameter of boiler; width of side flues, one-seventh diameter of boiler.

The Use of Gas in Smoke Abatement

On Thursday morning a visit was paid to the Barton Power Station of the Manchester Corporation, and in the afternoon the use of gas in smoke abatement was discussed.

Sir Arthur Duckham, K.C.B., President of the Institution of Chemical Engineers, who was to have given an address on "Gas Undertakings as Fuel Providers," was unable to be present through indisposition, but his colleague, Dr. Smith, spoke on the contribution that the gas industry might make towards the elimination of the smoke nuisance. Dr. Smith urged that the smoke nuisance was mainly due to domestic smoke, and that gas and coke could be used more cheaply than coal for domestic purposes. Although gas on a heat-unit basis was more expensive, it was cheaper when used over a period, because it was employed only when required. Coke was not as good or as convenient as gas, but as long as solid fuels were used gas undertakings should urge the advantages of coke for domestic use.

"The Fuel of the Future" was discussed by Mr. F. W. Goodenough, who said that for the progress and prosperity of the country it was essential that the fuel used in our homes and factories should—with the minimum cost to the consumer, the smallest demand on our coal reserves, and with the maximum economy in transport—assist the manufacturer to secure the maximum high-quality output, reduce household drudgery to a minimum, preserve the valuable constituents of coal and avoid pollution of the air with smoke. Gas and its companion by-product coke, were, it was maintained, the only fuels that satisfied these requirements. Electricity had an immense and growing field of usefulness, but it was both wasteful and costly to distribute heat derived from coal in the form of electricity. From 80 to 95 per cent. of the heat of the coal used in generating electricity was lost, whereas in a gas-works the loss was less than 25 per cent. In the electrical power station the valuable constituents of coal were lost that were recovered in the gasworks. The question was not solely one of cost, for questions of waste, storage, space, transport had to be considered, but where the cost of gaseous fuel was found to be too high, coke would generally be found the best means of securing fuel efficiency.

Mr. E. W. L. Nicol, A.M.I.E.E., read a paper on "Gas Coke in relation to Industrial and Domestic Smoke Prevention and Fuel Economy," in which he pointed out that the question of smoke prevention was inseparable from that of coal conservation, and that economy in fuel practice necessarily involved the prevention of smoke. There was every incentive to promote improvement in the utilisation of our coal resources, especially in view of our increasing dependence on foreign liquid fuels. Progress could only be made by providing smokeless fuels in adequate quantities and in a form suitable for use in old as well as modern types of heating apparatus. Modern heating apparatus required for efficient operation, not a semi-volatile fuel such as low-temperature coke, but a concentrated fuel with a minimum of volatile matter. Natural smokeless fuels such as anthracite existed in insufficient quantity in this country, and, although it was not suggested that bituminous coal could not be consumed without smoke, such coal caused most of the smoke nuisance. Pulverised fuel could be consumed smokelessly and efficiently, but it had been stated that 50 to 80 per cent. of the ash of the fuel was dispersed from the chimney, and the resulting nuisance would be worse than that of smoke. Oil-firing with cheap tar-oils had many advantages, but fuel-oil was an imported commodity. The favourite panaceas for the smoke nuisance were at present low-temperature fuels and the generation of abundant electricity; but the practical and financial difficulties were almost insurmountable. By treating all bituminous coals as raw materials for making smokeless fuel, fertilisers and other products, an advance would be made. Of the 189 million tons of coal consumed annually, 139 million t. is burned in the raw state. No coal capable of profitable carbonisation should be used in its crude state. The objection advanced against this proposal that it would be difficult to sell the principal secondary product—coke—did not hold good, and the demand for coke should keep pace with production, now amounting to some 8 million t. yearly. The direct and growing influence of coke in mitigating the smoke nuisance could be gauged by the increasing use of coke-fired domestic boilers; whilst in the industrial field, the use of coke for many industrial purposes had proved both practicable and economical. An important use was as a diluent of coal in the sandwich system of fuel blending, thus enabling the smokeless combustion of low-grade coal. The sandwich system was now used in several large power stations of high efficiency. The chief advantages of coke were that there was practically no difference between its gross and net calorific power; it required less furnace volume than coal; it facilitated the use of low-grade coal; it was smokeless, and gave an efficiency of combustion under suitable circumstances about equal to that of pulverised fuel.

(Point was lent to the proceedings by the development of a very thick fog.)

Electricity and Smoke Abatement.

At the afternoon session the Conference met to discuss the use of electricity in smoke abatement. Mr. J. Frith, explaining how electricity could help to solve the problem, said that the substitution of electric power generated in large, well-managed power stations for the small private plant, would not only reduce the total amount of coal burnt to one-tenth, but would reduce the smoke produced by the same proportion. More could be done to utilise the waste heat from fuel-burning electric generating stations, and much smoke could be avoided in the metallurgical industry by the use of electric furnaces. The influence of electricity on the domestic smoke problem was considered by Mr. J. W. Beauchamp,

who pointed out that it was time to consider the design of houses in relation to the equipment. Another paper was that by Prof. M. Walker on "The Use of Power other than that produced by Coal." At the final session, Ex-Bailie W. B. Smith, of Glasgow, gave a popular lecture on "The Cost of a Smoky Atmosphere."

The Exhibition

The *Manchester Guardian* says that for the average citizen the Smoke Abatement Exhibition is a revelation of the incredible waste in which he has indulged as a matter of course from his youth upwards. The various firms that exhibited have certainly done their best to touch the vision of the average citizen, as well as the boiler owner. Amongst the most striking stands is one which shows the innumerable chemical products wasted by the coal burnt in household grates and one which illustrates the damage done by smoke to the health of persons and to buildings. These two stands provide an admirable introduction to a most interesting assembly of smoke-preventing devices, and of means of heating and other appliances for private houses.

The exhibits shown by Sir W. H. Bailey and Co., Ltd., illustrate the complete series of boiler mountings supplied by this firm, including valves of all kinds, fusible plugs, water and steam gauges, vertical boiler feed pumps, air compressors, recording gyrometers, pyrometers for taking the temperature of flue gases and many more besides.

The Crosthwaite Engineering and Furnace Co., Ltd., show a new and improved type of mechanical stoker and self-cleaning furnace, which gives complete combustion of the fuel, elimination of smoke without the need for admitting excess of air, and easy and simple working. The object is to retain the advantages of hand firing without the disadvantages of mechanical stoking. The stoker can be adapted for use with either self-cleaning or fixed furnaces. A special point of the furnace is the new design of grate bar, which will not burn out or warp. Other apparatus by Messrs. Crosthwaite includes coal- or ash-conveying plant, a patent forced-draught furnace designed to burn both small and refuse fuels efficiently, and a variety of heavy machinery.

The Fusion Corporation, Ltd., of Middlewich, exhibit a working model of the "Fusion" low-temperature retort for treating oil shales, peat, sawdust, coal, cannel, or any other bituminous material for the recovery of low-temperature crude oils, and finely divided coke. The coke is said to be highly suitable both for suction gas plant use and powdered fuel firing, as well as for making briquettes. The model of the fusion retort was operating on sand to show the action of the feeder, the travel of the material through the retort, and the discharge of the spent material. In practice the retorts are fired either by hand, producer gas or other suitable means, the ignited gases being led into the combustion chamber and distributed from the combustion chamber by a very ingenious arrangement of small distributing ports which allow of the easy and absolute control of the temperature at any point along the length of the retort. It is claimed that the temperature can be held steady within 10° C. of any predetermined temperature for any desired length of time. The automatic feeder is driven from the rotating tube of the retort itself and, therefore, revolves at a definite speed comparable with the retort; the amount to be passed through the feeder can be adjusted, even whilst the retort itself is in operation. The feeder is also so arranged as to form a seal at the feed end to prevent the ingress of air. Lengths of breaker are laid loosely in the retort tube, and as the tube rotates the breakers fall over and over due to their own weight, giving a hammer and slicing blow to the material being treated, thus keeping the retort shell free from scale or carbon deposit, and reducing the amount of fuel required for heating. The principle of this retort is also applicable to propositions such as the drying of caustic lime sludge, china clay, waste from water-softening plants, sewage tank residue, or other material with very high water contents, and it has also been applied to low-temperature chemical process work and to the slaking of lime. A new type of dust arrestor, on an entirely new principle, was also shown.

Coal users found a good deal of interest at the stand of A. Gallenkamp and Co., Ltd., whose exhibit consists of apparatus necessary for ensuring fuel economy. For a determination of the calorific value of coal, there are the Darling calorimeter, easy to manipulate and inexpensive, or the Mahler-Kroeker bomb calorimeter for highly accurate determinations. Apparatus for determining the contents of moisture, ash, sulphur, volatile matter and fixed carbon is displayed in an attractive manner, and a descriptive pamphlet that was obtainable at the stand provides some useful hints on fuel economy. Amongst other apparatus on show are the Lessing electric coking furnace, for use in estimating coking properties, the Davies crucible furnace for estimating volatile matter, Orsat's apparatus for analysing flue gases, carbon dioxide recorders, low and high temperature assay apparatus for coal as used by the Fuel Research Board, thermometers, pyrometers—everything required to ascertain the value of the coal, and its behaviour under the furnace, so that the twin aims of fuel economy and smoke abatement could be satisfied.

Gibbons Brothers, Ltd., of Dudley, show the Gibbons-Van Marle patent machine for charging and discharging industrial furnaces, which eliminates the waste of time and labour attending the charging of large muffles and furnaces by hand, discharging or charging occupying less than a minute, compared with 10 to 20 minutes with hand tools. The first machine was put to work in Birmingham some three years ago and has worked continuously and with a minimum of attention ever since. Both hand and electrically operated types are made. Gibbons Brothers also make gas-fired regenerative furnaces and muffles suitable for all industrial processes, of particular interest being a new and highly efficient gas furnace. This muffle, which is heated externally only, will attain a temperature of 1500° C. when working on natural draught and burning 900 cb. ft. of gas (430 B.Th.U.) hourly. Bunsen burners and injectors are eliminated, and gas and air are admitted

to the combustion chamber by fireclay ports, both air and gas being pre-heated by a regenerator of ample size. Particular attention has been paid to heat transference and insulation, and the furnace is said to have given surprising results.

The Atritor coal-pulverising and firing machine is exhibited by Alfred Herbert, Ltd., of Coventry, who issue a booklet, "On Pulverised Fuel," which should be consulted by those who wish to study British methods.

The exhibit of Frank Pearn and Co., Ltd., is included in the model boiler house which forms such an interesting feature of the exhibition. A vertical direct-acting pump is shown working under steam at 100 lb. pressure; the valve gear of this pump is designed to ensure that the stroke is full, whilst providing a steam cushion at the end of each stroke so that the pump works steadily without knocking. The pump is capable of delivering 1000 gall. per hour with and against a steam pressure of 200 lb. per sq. in. An electrically-driven vertical treble ram pump is shown that is capable of delivering 1000 gall. per hour against a pressure of 100 lb. per sq. in.; pumps of this type are made by Messrs. Pearn for any capacity and pressure required for boiler feeding when an electric drive is preferred.

The Lea Recorder Co., Ltd., Manchester, shows apparatus for the measurement of coal and water in operation on a Lancashire type boiler fitted with Proctor mechanical stokers. A good check can be obtained in this way on the efficiency of the plant, especially when used in conjunction with the V-notch boiler-feed recorder, also shown in operation. Lea coal meters are also shown for chain-grate stokers, and a model "Cubi-Meter" is in operation to illustrate the volumetric measurement of coal, ores, etc., by this method. Another new feature is the Automatic Sampler for the continuous sampling of liquids of any description.

On the stand of Leigh Smokeless Fuels, Ltd., are pure coal briquettes, smokeless fuels and light and heavy oils. This company, which operates under the patents of Sutcliffe, Speakman and Co. for making smokeless fuel, provides an interesting display of their smokeless fuels, a noteworthy point of its processes being that they combine the advantages of high and low temperature carbonisation. The "pure coal" briquettes, which burn completely and regularly and leave no clinker, are used for industrial as well as domestic heating. According to the temperature of carbonisation, the pure coal briquettes make a valuable smokeless fuel, an artificial anthracite, or a blast furnace coke. The artificial anthracite is recommended for use in anthracite stoves or for suction gas engines, and the blast furnace coke will, it is anticipated, enable a saving of some 3 to 4 cwt. of coke per ton of pig iron made. A plant is being erected at Leigh to manufacture these products, and the company is prepared to grant licences to operate the processes under its patents.

Meldrums, Ltd., of Timperley, exhibit a Meldrum "Koker" type of stoker fitted to a model boiler front. This machine-fired furnace works with an entire freedom from smoke, grit, or noise, and nothing but a slight haze is visible from a chimney serving a dozen boilers fitted with this stoker. Another type of stoker, illustrated by prints, is the "Sprinkler" stoker for installation with a fixed grate. Both types of stoker are suitable for use with natural, induced, forced or balanced draught. The structure of the Meldrum forced draught furnace front is clearly shown by a front mounted on a stand, and a section of the Meldrum patent interlocking fire-bars is also shown. A valvular dead plate, which admits secondary air at the point of combustion when the furnace door is closed, and a split bridge for admission of further secondary air at the bridge, are of interest for promoting smoke abatement, for which there is also the smoke-prevention door to replace the ordinary fire-door on vertical, Cochran, and loco type boilers. Destructor furnaces are a speciality of this firm, and ample information on the many types manufactured is provided. A Meldrum oil burner and a group of pieces of chemical plant made in Meldrum acid-resistant metal complete an informative exhibit.

The model boiler house showing most of the points in a typical Lancashire boiler which require attention for economy, efficiency and smokelessness was a symposium of exhibits by many firms, including Babcock and Willcox, the Chemical Engineering Co., Ltd., A. Gallenkamp and Co., Ltd., E. Green and Son, Ltd. (the "Green" economiser), the Lea Recorder Co., Ltd., Newalls Insulation Co., Ltd., Frank Pearn and Co., Ltd., and several others.

An interesting demonstration of the advantages of fuel oil is arranged by Shell-Mex, Ltd., who have installed a Cochran vertical boiler equipped with Clyde oil-fuel burners (steam jet), thus demonstrating (with the help of a smoke observation apparatus) the perfect smokeless combustion of the fuel. This company claims that when the many advantages of oil are taken into account and given their proper monetary value, Mex fuel oil will generally be found to be considerably cheaper than coal. A well-illustrated selection of literature is available showing the progress made in oil-burning in the principal buildings of London, and there is a booklet describing the oil-fuel installation at the works of J. S. Fry and Sons, Ltd., at Bristol.

The Howden-Ljungstrom air preheaters on the stand of the same name are of importance to those interested in fuel economy and increased steaming capacity. This air preheater can be applied to any type of boiler and design of furnace, and is normally designed to extract 70 per cent. of the available heat in the waste flue gases and transfer it to the air required for combustion. By means of a slowly revolving cylinder containing the heating elements (a large number of thin alternating corrugated and plain steel sheets, which form small triangular channels for the air and hot gases to pass in countercurrent) the heat is transferred continuously. Such a preheater, applied to a Lancashire boiler, gave a fuel-saving of 15·2 per cent. At the same stand is the Howden-Burdon oil-gas furnace.

The Midland Coal Products, Ltd., utilise a method of carbonisation specially adapted to feebly caking,

or a blend of strongly caking and feebly caking coal slacks, and the exhibit is designed to show by stages the products thus obtained. In addition to smokeless fuel, fuel oils and gas, interesting specimens of disinfectants and paints are shown.

The stand of Royles, Ltd., of Irlam, contains samples of the Row indented copper tubes, a working exhibit of the Row air-heater, the Royle hydraulic test pump, the Row storage pattern calorifier, and a series of steam traps and valves.

The Triumph F.D. stoker, exhibited by Triumph Stoker Ltd., is of the sprinkler type, the result being perfect combustion without smoke. For a description of the chief characteristics of this stoker reference may be made to the firm's catalogues, "A" and "F.D."

The Thermal Syndicate could not be absent from a smoke-abatement exhibition, and showed a representative selection of the many products for home and industrial use which are made in Vitreosil.

The Exhibition remains open until the evening of November 15.

PULP AND PAPER INDUSTRY IN CANADA

The International Paper Co. is erecting a new annex to its present mills at Three Rivers, at a cost of over $2,000,000.

The St. Regis Pulp and Paper Co., has purchased a site at Cape Rouge, near Quebec, for the erection of its three mills.

The mills of the Chicoutimi Pulp and Paper Co., which closed down after the bankruptcy of Becker and Co., have resumed operations. Price Bros., Co., Ltd., is commencing the erection of a large mill at St. Joseph d'Alma, Lake St. John, Quebec. The mill will have an initial daily output of 200 tons of paper, increasing to 600 t.

A third paper mill is to be established in Newfoundland in the Handor Valley in the north east portion of the island, with a capacity of 300 t. of newsprint daily.

The annual statement of Spanish River Pulp and Paper Mills Ltd. (Ontario) shows gross profits of $5,038,029 as compared with $4,008,155 on the 30 June, 1923. The gross profit for the past year is equivalent to 26·6 per cent. on the common stock. The working capital stands $9,012,994 and total assets at $44,704,649.

The International Pulp and Paper Co., will expend $5,000,000 on enlarging its paper plant at Three Rivers, Quebec. Three new machines for newsprint will be installed. This will increase capacity to 600 tons of paper daily.

The Quebec Pulp and Paper Corporation has taken over the Saguenay Company, and its main subsidiary the Chicoutimi Pulp Co., both companies which were formerly operated by the Becker interests.

The National Pulp Corporation, Ltd., is to erect a small newsprint mill at Oshawa, Ontario. A company composed of Quebec capitalists is to erect a large pulp mill in the Megiscane river district in Abitibi, Northern Quebec.

THE STREATFEILD MEMORIAL LECTURE

The annual address in memory of the late Mr. F. W. Streatfeild was delivered at the Finsbury Technical College, on November 6, by Mr. Julian L. Baker, the subject being "The Chemist and the Fermentation Industries." The object of the lecture was to stress the economic and scientific importance of the fermentation industries and to show the very fruitful possibilities of these industries for research.

The revenue from beer and spirits alone accounted for, roughly, one-sixth of the total revenue of the country, this large sum being obtained from materials almost wholly derived from agriculture and largely grown in this country.

Following a general description of the processes of brewing, it was pointed out how little we know of what actually takes place, and no real advance could be claimed since O'Sullivan and Brown and Morris, by their work on the action of amylase on starch, set the brewing world thinking. The slow progress made during the last forty years was not surprising, for the difficulties of the investigator were profound owing to the complexity of the changes involved. The work by Brown, Miller, Maquenne, Roux, Ling and the lecturer was outlined, and the conclusion drawn that starch was not made up of a polymerised basal unit, and that Pictet, Carrer and Irvine were probably in error in regarding starch as consisting of a single substance. It thus appeared hopeful that we might soon be in the possession of reliable information concerning one constituent of the barley-corn, though there was still a great deal to be done on the proteins of the barley. Under such conditions it was not surprising that brewing was still regarded as a craft and the brewer as an empiricist.

After describing the work being conducted under the auspices of the Research Scheme of the Institute of Brewing at Rothamsted and elsewhere, the difficulty was emphasised of convincing the industry of the need for research owing to the British instinct to leave well alone. The general trend of the industry, however, was progressive, and firms were beginning to see the necessity that their brewers should be men well-trained in science and engineering. The time was not far remote when the services of chemists would be in greater demand in breweries than at present. Recent work on the production of glycerol lactic acid by fermentation processes was outlined. Enough evidence was adduced to show that the industries based on the activity of micro-organisms were of profound importance to the community, and that the fields of investigation, both academical and technical, in such industries were limitless.

At the conclusion of his address Mr. Julian Baker referred to the recent decision of the City and Guilds of London Institute to close the College in 1926. The withdrawal of the London County Council grant of £10,000 per annum, to take effect in 1926, was largely responsible for the position. He thought the decline in the number of students, given as a reason for the grant withdrawal, had been unduly exaggerated, and was no greater than might be anticipated in view of the action taken in 1920 to close the College and admit no new students in the Session

1920–21. Immediate action was necessary on the part of those who valued the real and practical educational facilities offered by the College for the last forty-six years, due in the first instance to the curriculum provided in chemistry and engineering by its first teachers, Armstrong, Perry and Ayrton. The practical courses unfettered by any particular examination syllabus ought to continue, and it was to be hoped that an influential deputation of manufacturers and educationists would find a way to enable the Institution to continue its work.

After presenting the Streatfeild Memorial Medal to the lecturer, the chairman, Prof. H. E. Armstrong, gave an account of his early work at Finsbury with Perry and Ayrton, and emphasised the value which the training had always had in promoting the application of science to industry. The courses for training chemists and engineers were unique. Chemical engineering was no new subject at Finsbury. All its chemists received training in the principles of engineering as part of the ordinary course.

Mr. A. Chaston Chapman considered that the sound practical training, with freedom from examination syllabuses, the great tradition of its past students and teachers, and the service it had rendered should assure the continuance of Finsbury. Everything possible should be done in order that its work might be continued and developed.

Prof. G. T. Morgan, in arguing for a continuance of its work, pointed out that the good-will of the College and traditions associated with it could not be continued elsewhere; they would be irretrievably lost if it closed.

Prof. Donnan who was unable to be present, expressed his views by letter: "It would have given me great pleasure to express my views on the educational value of the old college, which, in my opinion, did excellent work of real importance for the country. The whole cause of higher education in London is suffering at present from the want of autonomy in the principal Colleges as regards the examination for the B.Sc. degree. The old Finsbury system was and is the only one which produces good results, and is, in fact, the method employed by other civilised countries, with the exception of England. I am, therefore, as you know, a hearty supporter of the system which enabled Finsbury College to produce a long succession of men who have gone forth into the world and done good work, and held high positions in engineering and chemistry.

Mr. F. H. Carr agreed that the training offered at Finsbury was of great value to the industries. He considered that we were suffering greatly from what he would term the respectability of degrees.

Mr. A. J. Chapman, President of the Old Students' Association, described the work now being done by the association to save the college. He felt that where the Council differed from some authorities was on the question of the necessity of a man taking a degree at the end of his training. Finsbury had always held that this only fettered the curriculum, and the reason Finsbury had been such a success in the past was the freedom of the course given there, whereby each of the three departments of the College obtained a good knowledge of the other two. The Old Students' Association had been assured of the inter[est] the four great Institutions took in the matter. Th[e] Institute of Chemistry, Institutions of Civil, Electric[al] and Mechanical Engineers. Many of the City Guil[ds] had been approached, and so also had the manufa[c]turers through their trade organisations. It wa[s] hoped that some means would be found to preve[nt] the closure.

FORTHCOMING EVENTS

Nov. 17. Society of Chemical Industry, *Yorkshir[e] Section*, Great Northern Hotel (Room 15), Leed[s] at 7.15 p.m. "Chemistry of the Distillation [o]f Fatty Acids," by G. F. Pickering.

Nov. 17. University of Birmingham Chemical Society Chemical Lecture Theatre, Edgbaston, Birmingham, at 5.30 p.m. "The Chemistry of Blood," by S. H. Edgar.

Nov. 17. Institution of Mechanical Engineers, Storey's Gate, Westminster, London, S.W. 1, at 7 p.m "The Production of a Modern Technical Journal," by L. Pendred.

Nov. 17. Institution of the Rubber Industry, Join[t] Meeting with the Society of Chemical Industry, Engineers' Club, Coventry Street, Piccadilly, W., at 8 p.m. "Latex, its Chemistry and the Development of its Industrial Applications," by Dr. A. Van Rossem. B. D. Porritt, M.Sc., will open the discussion on behalf of the S.C.I.

Nov. 17. Faraday Society, Ordinary Meeting, Rooms of the Chemical Society, Burlington House, Piccadilly, London, W. 1, at 8 p.m.

The following papers will be read:—(1) "The Hydrolysis of Alkali Cyanides in Aqueous Solution," by R. W. E. B. Harman and F. P. Worley. (2) "Note on the Expansion of Water while Freezing" by A. P. Laurie. (3) "The Viscosity of Reversible Emulsions," by S. S. Joshi. (4) "On the Viscosities of Liquids at their Boiling Points," by D. B. MacLeod. (5) "The Kinetic Theory of Evaporation" by D. B. MacLeod. (6) "New Design for Apparatus to Measure the Coefficient of Deviation from Boyle's Law and the Determination of this Coefficient for Acetylene," by J. T. Howarth and F. P. Burt. There will also be an exhibition of physico-chemical Apparatus by Messrs. A. Gallenkamp and Co., Ltd.

Nov. 18. Royal Photographic Society, 35, Russell Square, London, W.C. 1, at 7 p.m. (1) "Note on the Relationship of Photographic Emulsion Fog to Grain Size," by A. P. H. Trivelli, E. P. Wightman, and S. E. Sheppard. (2) "Grain Size and Distribution in Emulsions," by S. E. Sheppard. (3) "Conditions Governing the Behaviour of the Silver Bromide Grains during Development," by L. F. Davidson. (4) "Demonstrations of the Cambridge Photographic Ophthalmoscope and Cambridge Record Measuring Machine," by the Cambridge Instrument Company.

Nov. 18. Institute of Brewing, *Scottish Section*, Caledonian Station Hotel, Edinburgh. "Hot Aeration," by Dr. Clerk Ranken.

Nov. 18. Institution of Civil Engineers, Ordinary Meeting, Great George Street, Westminster, London, S.W. 1, at 6 p.m. "Notes on Modern Practice in Road-Making," by W. J. Hadfield.

Nov. 18. Imperial College Chemical Society, Royal College of Science, South Kensington, London, S.W. 7, at 5 p.m. "The Manufacture of Glass," by Dr. M. W. Travers, F.R.S.

Nov. 19. Society of Glass Technology, Lecture Theatre, Department of Coal Gas and Fuel Industries, The University, Leeds, at 3 p.m. (1) "A Note on the Glass Houses of the Leeds District, in the Seventeenth, Eighteenth and Nineteenth Centuries," by F. Buckley. (2) "A Striking Instance of Fireclay Corrosion through the Action of Saltcake," by Prof. W. E. S. Turner. (3) "A Note on Some Properties of a Sandstone Block after Use in a Glass Furnace," by H. S. Houldsworth. (4) "The Production of Colourless Glass in Tank Furnaces, with Special Reference to the Use of Selenium. Part IV. The Influence of Arsenious Oxide" by A. Cousen and Prof. W. E. S. Turner.

Nov. 19. Institute of Chemistry, *London Section*, 30, Russell Square, London, W.C. 1, at 8 p.m. Discussion to be opened by Dr. J. J. Fox and Mr. V. Stott, on "The Standardisation of Scientific Glassware with particular reference to Units of Volume."

Nov. 19. Society of Chemical Industry, *Bristol Section*, Visit to the New University Buildings. Members will meet at 2.30 p.m. outside the Chemical Department, Woodland Road, Bristol.

Nov. 19. Institute of Chemistry and Society of Chemical Industry, the Caledonian Station Hotel, Edinburgh, at 8 p.m. "The Profession of Chemistry," by Prof. G. G. Henderson.

Nov. 20. Institute of Chemistry, *Belfast and District Section*, Visit to the Linen Industry Research Association at Lambeg. "The Work of the Institute," by Dr. J. Vargas Eyre.

Nov. 20. Institution of Mechanical Engineers, Queen's Hotel, Birmingham, at 6.30 p.m. "Design of an Up-to-date Factory," by F. W. Suffield.

Nov. 20. Chemical Society, Ordinary Scientific Meeting, Burlington House, Piccadilly, London, W. 1, at 8 p.m. (1) "The Sulphur Compounds of Kimmeridge Shale Oil. Part I," by F. Challenger, J. R. A. Jinks, and J. Haslam. (2) "The Interaction of Thiocyanogen and of Hydrogen Sulphide with Unsaturated Compounds. Part II," by F. Challenger and T. H. Bott.

Nov. 21. University of London, King's College, Strand, W.C. 2, at 5.30 p.m. "Scientific Method," by E. S. Russell, M.A.

Nov. 21. Society of Chemical Industry, *Liverpool Section*, the Muspratt Lecture Theatre, The University, Liverpool, at 6 p.m. "Notes on Alloy Metals used in Alloy Steels," by J. L. F. Vogel.

Nov. 21. Institute of Metals, *Sheffield Section*, Conjoint Meeting of Societies at the Sheffield Metallurgical Association's Rooms, 198, West Street, Sheffield, at 7.30 p.m. "Non-Ferrous Metals in the Foundry," by A. Marks.

Nov. 21. Institution of Mechanical Engineers, Joint Meeting with the Liverpool Engineering Society, at 9, The Temple, Dale Street, Liverpool, at 7.30 p.m. "Reducing or Pass-Out Turbines," by W. S. Burge and P. J. Chittendon.

Nov. 22. Institution of Mechanical Engineers, *Midland Section*, Visit to the Birmingham Small Arms Co., Small Heath, Birmingham.

Nov. 24. Institution of Electrical Engineers, Savoy Place, London, W.C. 2, at 7 p.m. "Discussion on the Electrostatic Wattmeter used for Measuring Dielectric Losses in Cables," opened by N. A. Allen.

Nov. 24. Royal Society of Arts, John Street, Adelphi, London, W.C. 2, at 8 p.m. "Modern Colour Problems," by L. C. Martin.

SOCIETY OF CHEMICAL INDUSTRY

SUSPENSION OF ENTRANCE FEE

As an inducement to Chemists to become members, the Council has resolved that no entrance fee shall be paid by members joining the Society in 1925.

A form of application for membership was inserted at the end of this Section in the issue of the Journal for October 17, and it is hoped that it may be used to introduce a new member for next year.

BACK NUMBERS OF JOURNAL

The General Secretary will be glad to hear from Members or Subscribers who have copies of the *Journal* for January 5, 1923, or January 4, 1924, that they are willing to dispose of to the Society.

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

VOL. IX (1924)

This volume is in course of preparation, and an order form will be sent out in due course with the application for the annual subscription for 1925.

The list of subjects dealt with and the names of the authors are as follows:—

Plant and Machinery	S. G. M. Ure.
Fuel	J. W. Cobb and H. J. Hodsman.
Gas—Destructive Distillation—Tar Products	W. B. Davidson.
Mineral Oils	S. J. M. Auld.
Colouring Matters and Dyes	E. H. Rodd.
Fibres, Textiles, Cellulose, and Paper	S. H. Higgins.
Bleaching, Dyeing, Printing, and Finishing	A. J. Hall.
Acids, Alkalis, Salts, etc.	P. Parrish.
Glass	E. A. Coad-Pryor.
Ceramics, Building Materials, and Refractories	W. J. Rees.
Iron and Steel	C. O. Bannister.
Iron-Ferrous Metals	C. A. Edwards.
Electro-Chemical and Electro-Metallurgical Industries	J. N. Pring.
Oils, Fats, and Waxes	H. M. Langton.
Paints, Pigments, Varnishes, and Resins	C. A. Klein.
Indiarubber	D. F. Twiss.
Leather and Glue	D. M. McCandlish.
Soils and Fertilisers	H. J. Page.
Sugars, Starches, and Gums	L. Eynon and J. H. Lane.
Fermentation Industries	H. L. Hind.
Foods	G. W. Monier-Williams.
Sanitation and Water Purification	J. H. Johnston.
Fine Chemicals, Medicinal Substances, Essential Oils	H. King.
Photographic Materials and Processes	W. Clark.
Explosives	J. Weir.

DEATHS

Jackson, Dr. W. Hatchett (elected 1900), of the Radcliffe Library, Oxford, Librarian. On February 21, 1924.

Smith, Henry G. (elected 1902), of "Dunbourne," Shirley Road, Roseville, Sydney, N.S.W., Chemist. On September, 19, 1924.

Spence, John W. (elected 1883), of Darley House, West Didsbury, Manchester, Drysalter. On October 22, 1924.

BRISTOL SECTION

The second meeting was held jointly with the Institute of Chemistry on November 6, in the University Chemical Department, there being an excellent attendance. The certificate of Fellowship of the the Institute was presented, by Mr. C. J. Waterfall, to Mr. E. J. Holmyard, M.A., who then read a most interesting paper on "The Present Position of the Geber Problem."

In considering the history of chemistry we may remember the statement that "in no department is the modern world more deeply rooted in the past than in that of science. The scientific outlook is essentially a living tradition, for the correct application of which a knowledge of its history is essential. Chemistry is at least as surely built on its past as is our religion, our social organisation or our political system." This view was gaining widespread support, and the history of chemistry was now generally regarded as of equal importance with the more practical aspects of the subject.

One of the most important problems in the history of chemistry was that concerned with the development of chemical knowledge in Islam and its transmission thence to Latin Europe in the early Middle Ages. Much interest centred round certain works ascribed to one Geber, which appeared in Latin in the thirteenth century and showed a clear and accurate acquaintance with many fundamental chemical substances and facts.

Evidence was adduced by the lecturer to show that "Geber" was Jabir ibn Hayyan, the great Muslim chemist who flourished under the Caliph Harun al-Raschid of "Arabian Nights" fame. The Latin works were to be regarded, in all probability, not as literal translations from the Arabic, but as free renderings or compilations. The knowledge they contained was, in very large part, to be found in Arabic works by Jabir and others still preserved in the libraries of Europe, India and Cairo.

An excellent set of lantern slides illustrating forms of apparatus and other matters pertaining to Alchemy concluded the lecture, which was productive of a good discussion, in which Drs. Hooper and Rixon, Messrs. Waterfall, Menzies, Jones and others took part.

UNIVERSITY OF BIRMINGHAM CHEMICAL SOCIETY

At the meeting held on November 3, Mr. J. R. Dolphin, B.Sc., delivered a paper on "The Application of Science to the Production of Gems." After dealing with the properties of refraction, pleochroism, hardness and density, the lecturer showed that miscroscopical examination was necessary to distinguish between "synthetic" and real gems. Verneuil's method of producing colourless and coloured corundums was fully described. The colouring agents used in the production of the ruby, yellow and blue sapphires, "synthetic topaz" and "scientific Alexandrite" were dealt with. In conclusion the distinction between "imitation" pearls and the Japanese culture pearl (Mikimoto pearls) were described and illustrated.

CHEMICAL SOCIETY

Consideration of the mechanism of the Walden inversion occupied the greater part of the time at a meeting held on Thursday, November 6. The first paper was read by Dr. J. Kenyon:—

Investigations on the dependence of rotatory power on chemical constitution. Part XXIV. Further experiments on the Walden Inversion. [With H. Phillips and H. G. Turley.]

LÆVOROTATORY lactic acid, which may be assumed to have a lævo-configuration, when esterified gives dextrorotatory ethyl lactate with $[\alpha]_D^{23} + 11{\cdot}29°$. This ester readily yields a *p*-toluenesulphonyl derivative from which dextrorotatory ethyl α-benzoxypropionate with $[\alpha]_D^{20} + 24{\cdot}57°$ can be prepared by interaction with potassium benzoate, whereas, by the action of benzoyl chloride on the same sample of dextrorotatory ethyl lactate, lævorotatory ethyl α-benzoxypropionate with $[\alpha]_D^{20} - 24{\cdot}59°$ is obtained. A complete inversion of *l*-lactic acid is indicated in the first case. Similarly dextrorotatory *a*-bromopropionic ester has been obtained by the interaction of the lævorotatory sulphonic ester with Grignard reagents. This reaction has an important bearing on the relative configurations of *l*-lactic acid and dextrorotatory α-bromopropionic acid and therefore on the theoretical aspect of the Walden inversion. An attempt is made to suggest the possible mechanism of the reactions described on the lines indicated by one of us (Part XVII., *T.*, 1923, 123, 44).

Prof. T. M. Lowry then gave an account of his explanation of:—

The Mechanism of the Walden Inversion.

THE speaker said that none of the older theories had secured general acceptance since it had always been necessary to postulate some entirely novel property of the asymmetric carbon atom, devised expressly in order to explain the phenomena in question. Illustrating his remarks with models, Prof. Lowry described the views of Fischer and of Werner, of Gadamer and Frankland, and exhibited Garner's device, manipulation of which involved a change of configuration of all three radicals P, Q, R, in the scheme $\begin{array}{cc} P & R \\ \multicolumn{2}{c}{C} \\ Q & + \end{array}$. His own conception of the mechanism was based on two propositions—(i) that there are two kinds of valency, one inert and the other active, reaction in organic as well as in inorganic chemistry taking place between ions, either "free" or "bound"; and (ii) that the carbon atom has two stable configurations, the tetrahedral form in neutral atoms easily and reversibly passing into a triangular and planar form when the atom is positively charged. Basing his arguments on the *X*-ray analysis of calcite and basic beryllium acetate, Prof. Lowry applied his two postulates to reactions such as those described in the previous paper. It was necessary to suppose that interchange occurred between an ionised and an esterified radical (involving the inter-conversion of a polar and a non-polar

linking), and that an intermediate additive, although ionic, compound was formed.

Dr. R. H. Pickard disagreed with Prof. Lowry's views. Since the Walden inversion always takes place in solution, reference to the *X*-ray structure of solids was quite beside the point. The previous authors had obtained the first example of a change where the inversion could be definitely ascribed to one stage of the reaction, and they had produced complete inversion without loss of rotatory power. Naturally, the explanation which they put forward must in the first place be special; a general theory such as that evolved by Prof. Lowry must take into account inversions which were complete, and partial. He was certain that much work which had led to racemisation had not found its way into chemical literature. Racemisation is, he said, a phenomenon which is preceded by subtraction; the other reactions are preceded by potential addition.

Dr. G. W. Clough congratulated the first authors on their valuable experimental contribution to the chemistry of the Walden inversion; the transformations of ethyl *p*-toluenesulphonyl-*d*-lactate were of great importance, especially as Freudenberg and Rhino had recently obtained optically active alanine-amide by the action of ammonia on the same compound. He asked whether Dr. Kenyon's theory was generally applicable, and suggested a similar investigation with ethyl phenylmethylglycollate as a crucial test. Prof. Lowry's theory was similar to that of Biilmann, and the question again arose whether an electrically charged carbon atom is asymmetric if it has only three groups attached to it, these groups being in the same plane as the carbon atom. The mechanism might apply to the action of water on active phenylchloroacetic acid, but complete racemisation occurs in this case. The theory apparently had not been applied to any concrete example from the work of Walden, McKenzie, Fischer, or their collaborators; it did not account for the difference in behaviour of an acid and its ester with a given reagent, neither did it indicate at which point in a Walden inversion change of configuration occurs. Finally, Prof. Lowry did not appear to have made any predictions which could be experimentally tested.

Dr. H. Phillips considered that whilst Prof. Lowry's theory suggested a possible mechanism for an abnormal reaction or racemisation, it did not appear to admit the possibility of predominance of the direct displacement reaction, unaccompanied by configurative change, as observed, *e.g.*, by Senter and Drew (*T.*, 1915, **107**, 638) in the formation of phenylaminoacetic acid. The application of either theory to the experimental results just communicated led to the same conclusion, namely that lævorotatory lactic acid has the same configuration as dextrorotatory α-bromopropionic acid, but the mechanism of the Walden inversion proposed by Prof. Lowry also appeared to demand that the action of water on the silver salt of dextrorotatory α-bromopropionic acid was an "abnormal" reaction, and hence to lead to a diametrically opposed conclusion.

Prof. Lowry, in reply, denied that his theory took account only of two alternatives, namely racemisation and complete inversion; his impression was that the facts so far brought forward in criticism were explainable in the manner he suggested.

Dr. E. B. Maxted then read the following paper:—

The adsorption of catalytically poisonous metals by platinum. Part I. The adsorption of lead and mercury.

The adsorption of lead and of mercury from dilute aqueous solutions of their salts has been studied, with the ultimate object of finding the variation in the activity of a platinum catalyst with the actual concentration of such inhibitants on its surface. In these adsorption measurements it was found, both for lead and for mercury, that the adsorbed concentration is directly proportional to the bulk concentration up to a region in the neighbourhood of the complete saturation of the surface of the platinum by the substance adsorbed. With the platinum employed, saturation was obtained with about 27 mg. of lead and about 8 mg. of mercury per gram of platinum. From the results obtained, it would appear that the activity of a platinum catalyst in the presence of such inhibitants is a linear function of the concentration of the poison on its surface.

Dr. W. E. Downey briefly described:—

A spectroscopic study of the luminescent oxidation of phosphorus. [With H. J. Emeléus.]

A spectroscopic examination of the light emitted when phosphorus burns has given the following results. When phosphorus burns in enriched air with a flame temperature of 800°, it shows five broad bands in the ultra-violet portion of the spectrum. Phosphorus burning in air under reduced pressure with a flame temperature of 125° emits five groups of narrow bands. The groups occupy the same positions as the bands obtained with the hot flame. Glowing phosphorus emits the same groups of narrow bands. This latter result contradicts Petrikaln's recent work but agrees with the earlier work of Centnerszwer and Petrikaln.

The President congratulated the authors, and expressed the hope that further papers would be forthcoming.

BRITISH ASSOCIATION OF CHEMISTS

The seventh Annual General Meeting was held at the Imperial College of Science, South Kensington, on October 25. Dr. Herbert Levinstein, retiring President of the Association, was in the chair.

In his address Dr. Levinstein complimented the Council upon the Annual Report, which in his opinion was well expressed and admirably concise. He alluded to those members who, by non-payment of their subscriptions, had seriously hindered the work of the Association, and appealed to all to make it a point of honour to recognise their clear duty in this respect. The report made very clear the unique

advantages that the Association had to confer. It had set up a standard of qualification; it supported substantially those of its members who were unemployed, and it had given, in the current year, legal aid to several of its members. Dr. Levinstein considered that those firms who were members of the Association of British Chemical Manufacturers would in many cases be prepared to give the Association substantial support; since the Association, pledged as it was to maintain a high standard for the profession, was able and willing to assist manufacturers in every possible way. It was greatly to the credit of the Association that it had been the first chemical organisation to wait successfully upon the President of the Board of Trade in connexion with the Dyestuffs Agreement controversy, and it was due, in large measure, to the Association's influence that a serious blow at the dyestuffs' industry of this country had been turned aside.

The general discussion was opened by Mr. Rowell, who said that decided progress had been made, but that a considerable increase in membership was necessary if there were to be any rapid advance. He indicated that Birmingham was preparing a scheme which he claimed had already proved successful on a small scale, and which might, in his opinion, be the more satisfactory as its scope increased. He hoped that the Association would collect information about salaries, so that particulars of minimum salaries paid might be obtained, and employers who paid less than the average amount might be approached with a view to adjustment of the matter.

Officers for the ensuing year were then elected as follows: President, Dr. E. F. Armstrong, F.R.S.; Vice-Presidents, W. E. Kay and F. Scholefield, M.Sc.; Registrar, David Bain, D.Sc.; General Secretary, I. Boodson, B.Sc.; Treasurer, H. E. J. Cory, M.Sc; Editor, H. T. F. Rhodes; Assistant Secretary, A Stewart Mills.

Mr. Knapp (Birmingham) then rose to put the Birmingham resolutions, which he explained were advanced as temporary measures with a view to economy. The first and second of these—that Council Meetings be held on alternate months, and that they be held at Derby, were accepted, but some discussion arose as to the third—that Sections be allowed to send at the Association's expense only one Councillor to each Council Meeting. After some energetic discussion in which Mr. W. E. Kay and the London Delegates took part, the amendment by Mr. E. R. Redgrove, Senior London Delegate, that the words "at the Association's expense" be deleted, was carried.

Mr. W. E. Kay, Vice-President of the Association, then proposed a vote of thanks to the retiring President. He pointed out how much moral and material help Dr. Levinstein had lent to the Association, and how its success had been due, in large measure, to his energy and enthusiasm. The vote of thanks was carried with loud acclamation.

The kindness of Prof. Baker of the Imperial College had made possible a tour of inspection of the laboratories and this took place at the close of the meeting. A very successful dinner was subsequently held at the Engineers' Club.

FARADAY SOCIETY

At the meeting, held on October 22, by the Faraday Society, the Geological Society and the Mineralogical Society, a general discussion was held on "The Physical Chemistry of Igneous Rock Formation."

In his paper on the "Homogeneous Equilibria in Magmatic Melts and their Bearing on the Processes of Igneous Rock-Formation," Mr. P. Niggli surveyed the phenomena in relation to the formation of rock, and gave a diagrammatic representation based on consideration of the homogeneous equilibria in the magma and connecting together a large number of natural phenomena, which thus represented a serviceable basis on which to discuss the laws pertaining to igneous rock.

Mr. A. F. Hallimond contributed a paper on "The Formation of Eutectic and Similar Structures in Silicate Melts," which dealt with the classification of silicate melts, the interpretation of structures, and concluded by suggesting a method of investigation consisting in examining polished surfaces under vertical illumination.

The object of the paper by Prof. C. H. Desch, entitled "The Theory of Crystallisation in Rock Magmas," was to suggest that the theory of crystallisation of rock magmas was best studied by the determination of the equilibrium diagrams of binary and ternary systems, work which has been undertaken with such remarkable success at the Geophysical Laboratory at Washington, combined with a detailed examination of the effects of cooling. For this latter purpose a knowledge of the viscosity of magmas and its variation with temperature and composition was required.

The paper by Prof. J. W. Gregory on "Magmatic Ores" dealt with gold-quartz veins, chromite, the magmatic iron ores, nickel ores in norite, and the intrusive pyritic massives. It pointed to the conclusion that the metalliferous ores formed during the direct consolidation of igneous magmas were at present unimportant; since the non-titaniferous ores which have been regarded as the test cases for magmatic iron ores, the nickel-sulphide ores in norites, the chief masses of chromite, and the great pyritic masses, were apparently deposited from solutions. The waters which had deposited primary ores were probably in most cases of magmatic origin, but the term magmatic as applied to ores should be restricted to its original meaning of direct consolidation from a molten magma.

Mr. J. W. Evans gave a paper entitled "Proposed Researches on the Chemistry and Physics of Igneous Magmas and Rocks" which dealt with research under uniform or hydraulic pressure and the effects of directed pressure, or shearing stress. Emphasis was laid on the theoretical and practical importance of investigating the origin, history and physical and chemical characters of igneous magmas and rocks, not only for determining the fundamental problems of the structure and past history of the earth, but because it had an immediate bearing on the mode of occurrence of metalliferous ores and therefore on the economic problems of mineral production.

Mr. W. A. Richardson, in his paper on "Some Ultimate Problems in Petrogenesis," stated that the science of petrogenesis took its origin and found its first problems in the recognition of affinities shown by rocks associated in the field, in such facts as the existence of petrographic provinces and diaschistic dykes. Since in its earlier stages petrology consisted of a vast mass of descriptive data, it was clear that the only way to bring the accumulated material into order was to limit the problems to definite areas. The extension of systematic surveys has now provided a body of data to which appeal can be made and statistical methods applied. Mr. Richardson concluded his paper by indicating what in his opinion were the chief needs of research in this connexion. They are as follows:—(1) The tabulation of the areas and exposed volumes of visible igneous rocks, so that further estimates of relative volumes could be made; (2) the systematic sampling of rock masses for chemical analysis; (3) investigations on the behaviour of silicate systems in the presence of vapour phases; (4) a more accurate and systematic determination of the temperature gradients in relation to the thermal problems of petrology, and of the geographical distribution of the gradients; (5) organised research into the question of the thermal state of the earth, especially the upper crust.

The paper entitled "Some Physical Properties of Silicate Glasses and their Possible Bearing on the History of Igneous Rocks," by Prof. W. E. S. Turner, dealt with the weathering and corrosion of silicate glasses and the density, thermal expansion and the compressibility of glass.

A "Review of Recent Work on the Origin and Differentiation of Igneous Rocks" was given by Mr. G. W. Tyrrell, who said that petrology may be considered as the natural history branch of physical chemistry. The application of physico-chemical principles to the study of igneous rocks has been hampered owing to the scarcity of exact experimental data on the behaviour of solutions approximating to igneous rocks in composition at high temperatures, but this handicap was now in process of being removed by the intensive and well-directed work of the Geophysical Institute at Washington. The paper also deals with crystallisation-differentiation, influence of water and other volatile constituents in magmatic differentiation, the origin of anorthosite, the origin of the alkaline rocks and the origin of alnöites and ultrabasic lamprophyres.

A cyanide war is apparently developing in North Ontario between the Cassel Cyanide Co., Glasgow, and the American Cyanamid Co. The former is offering sodium cyanide at under 15 cents. per pound, whilst the Cyanamid Co. supplies calcium cyanide at about 12 cents. per pound. It is reported that the American Company is endeavouring to reach an agreement with the Cassel Co., with the object of preventing a serious trade war.

CORRESPONDENCE

IS IT POSSIBLE TO PREDICT THE COURSE OF THE WALDEN INVERSION?

Sir,—At the last meeting of the Chemical Society I quoted Prof. Walden's statement that "We have many theories, too many theories, but we have not yet got *the* theory which will master the Walden Inversion." I also quoted his negative reply to the question, which I put to him in Holland at the van't Hoff Jubilee, whether he expected to find a theory which would enable us to predict the course of these actions. My own view, as I explained to him, is that the Walden Inversion gives us an opportunity of studying the mechanism of chemical change more intimately than does any other phenomenon hitherto investigated; we are therefore much more likely to learn from it, than to be able to use it as a "happy hunting ground" for prophets.

There is, however, another fundamental difficulty, in the fact that the Walden Inversion is essentially a study of *simultaneous reactions*. Of these there are at least two, namely, *direct substitution* and *indirect substitution*; and, in some cases, there may be a third, namely, *autoracemisation*, as distinguished from the racemisation which must result if direct and indirect substitution proceed with equal velocity, so as to give a 50 per cent. inversion. These three actions can all be interpreted by the modified Gadamer mechanism which I described; but, unless one could assign relative values to the three velocity-constants in question, the course of the action could not be predicted, since 40 per cent. of direct with 60 per cent. of indirect substitution would be described conventionally as inversion with partial racemisation, whilst 60 per cent. of direct with 40 per cent. of indirect substitution would be described as involving partial racemisation without inversion.

The examples recently described by the Battersea school owe much of their attractiveness to the fact that one of these actions preponderates over the others so strongly that they have almost ceased to be simultaneous. In cases such as these *qualitative* predictions may some day be possible, *e.g.*, that the action will proceed along Route No. 1 rather than along Route No. 2, perhaps (as I have suggested) on account of the mere bulk of the anions which are being exchanged. In all others, however, the predictions involve *quantitative* statements, which call for much more knowledge than we possess at present of the course of even the most commonplace reactions of organic chemistry. Thus, until we can predict the extent to which nitric acid will act as a nitrating agent, or as an oxidising agent on compounds such as bromocamphor, it is, in my opinion, unlikely that we shall be able to predict whether direct or indirect substitution will preponderate in cases in which both occur.—I am, Sir, etc., T. M. LOWRY

ECONOMY IN THE GENERATION OF STEAM

Sir,—I have read with interest the article by Mr. Chas. F. Wade on "Economy in the Generation and Utilisation of Steam" in the current number of *Chemistry and Industry*, and I note that it is

suggested that the loss due to unburned carbon in the ash of coal may be evaluated from "the difference between the absolute ash as found by proximate analysis, and the percentage of ashes removed." While this is, no doubt, theoretically always true, experience shows that the rule is one which frequently fails. It commonly happens when working with mechanical stokers and mechanical draught that the percentage of ashes removed during a boiler trial is less than that required by the proximate analysis, although there is a considerable percentage of unconsumed carbon in the refuse. This, of course, arises from fine dust carried forward by the gases which lodge in the various parts of the boiler and setting, and is (to a greater or lesser extent) carried clean up the chimney, and spread over the countryside.

The loss caused by combustible in the refuse can therefore be determined approximately only by weighing up such refuse as is removed *via* the ashpits, and by determining the carbon therein by chemical means.—Yours, etc.,

GODFREY W. HIMUS

Dearborn Chemical Co.,
Regent Street, London,
November 10, 1924

EARLY HISTORY OF ANTIMONY

Sir,—In my copy of Van der Linden's "De scriptis medicis" (Nuremberg, 1686) the following bibliographical references to Antimony are given, and some of them might prove of interest. For the sake of brevity, only names, dates and parts of titles are included here:—

Angelus Sala. Op. Med. Chym., 1647, 1650, 1680.
Angelus Sala. Anatomia Antimonii, 1617.
Baptista Codronchius, 1591, 1629.
Basilius Valentinus. Currus . . . 1671 (Kerckringius.) Amsterd.. in 12mo.
Basilius Valentinus. Azoth. . . . 1613 (Earliest publication of Valentinus mentioned by Linden).
Penotus. Tract. de Antimonio., 1594, 1602, 1613. 1616.
Arnold Kerner. Tetras Chymiatrica, 1618 (Erfurt).
Guernerus Rolfinkius. Dissert. Chem., 1679 (Jena).
Hildanus. (Medical), 1646.
Poppius. Basilica Antimonii., 1618 (Frankfort).
Grevinus. De Venenis., 1471 (Plantin., Antwerp).
Stenglius. Questiones 111, 1566.
Philologus. (Medical), 1538, 1545, 1575.
Hoffmannus. Exercitationes, . . . 1685 (Leyden).
Alexander a Suchten. De Secretis Antimonii, 1575 (Basel), 1670 (London).

In the event of further notes on the above being sought, I shall be pleased to furnish all I have found, six works attributed to Joachim Tankius are given as being published between 1604 and 1628. I find no mention of Tholde in the book, but a more thorough search [illegible] be more fruitful.—I am, Sir, etc.,

HAROLD A. AUDEN

Garston

PERSONAL AND OTHER ITEMS

The King has approved of the following awards this year by the president and council of the Royal Society:—A Royal medal to Sir Dugald Clerk, K.B.E., F.R.S., for his application of scientific principles to engineering problems, particularly to the development of the internal-combustion engine. A Royal medal to Dr. H. H. Dale, F.R.S., for his researches in pharmacology and physiology. The following awards have also been made by the president and Council:—The Copley medal to Sir E. Sharpey-Schafer, F.R.S., for his valuable work in physiology and histology. The Rumford medal to Mr. C. V. Boys, F.R.S., for his invention of the gas calorimeter. The Davy medal to Professor A. G. Perkin, F.R.S., for his researches on the structure of natural colouring matters. The Darwin medal to Professor T. H. Morgan, Foreign Member R.S., for his valuable work in zoology, especially his researches on heredity and cytology.

The following is the list of those recommended by the president and council of the Royal Society for election to the Council at the anniversary meeting on December 1:—President, Sir Charles Sherrington; Treasurer, Sir D. Prain; Secretaries, W. B. Hardy and J. H. Jeans; Foreign Secretary, Sir Richard Glazebrook. Other members of the Council are:—Sir F. Andrewes, Prof. J. H. Ashworth, Dr. F. W. Aston, Sir W. Bragg, Prof. S. Chapman, Sir D. Clerk, Dr. H. H. Dale, Prof. F. G. Donnan, Prof. A. S. Eddington, Prof. E. S. Goodrich, Sir T. Holland, Prof. J. B. Leathes, Dr. G. C. Simpson, Prof. J. F. Thorpe, Prof. F. E. Weiss and Prof. T. R. Merton. Lord Crawford and Sir O. Beit have been elected Fellows of the Royal Society under the Statute which permits of elections on the grounds of conspicuous services rendered to science. A donation of £500 has been made by Mrs. Tyndall, widow of Prof. John Tyndall, F.R.S., to be used at the discretion of the Tyndall Mining Bequest Committee, as a fund to meet out-of-pocket expenses incurred by the Tyndall Research Student in carrying out his investigations.

The following awards have been made by the Institution of Civil Engineers:—A Telford gold medal to Professor C. E. Inglis; Watt gold medals to Mr. H. N. Allott and Mr. F. L. Pearce; Telford premiums to Mr. A. J. Martin, Dr. H. E. Hurst, Mr. D. A. F. Watt, and Mr. D. H. Renfry; a Crampton prize to Mr. T. R. Nolan; and a Manby premium to Mr. H. T. Tudsbery. All these awards were for papers read at meetings of the Institution. Other awards for selected contributions included a Telford gold medal to Mr. E. H. Lamb, and premium to Mr. F. O. C. Temple, Mr. H. A. Lewis-Dale, Professor L. N. G. Filon, Mr. C. J. Gyde, and Mr. Wm. Burnside.

By an Order of Privy Council, dated October 30, Prof. E. P. Cathcart, M.D., D.Sc., F.R.S., Professor of Chemical Physiology in the University of Glasgow, has been appointed to the vacancy in the membership of the Medical Research Council, caused by the retirement of Prof. D. Noël Paton, M.D., F.R.S.

The list of awards for Ramsay Memorial Fellowships is as follows:—*British Fellowships*: Mr. Samuel Coffey, Ph.D., University College, London; Mr. A. F. Titley, B.Sc., Phil.D., University of Oxford; Mr. Sidney W. Saunders, B.Sc., University College, London. *Glasgow Fellowships*: Mr. T. S. Stevens, B.Sc., University of Oxford; Mr. Alex. Robertson, Ph.D. (since resigned on appointment to an International Fellowship in New York). *Canadian Fellowship*: Mr. Edward H. Boomer, Ph.D., University of Cambridge. *Danish Fellowship*: Mr. Kai J. Pedersen, University of Bristol. *Dutch Fellowship*: Dr. J. Kalff, University of Manchester. *French Fellowship*: Dr. H. Weiss, Royal Institution, London. *Greek Fellowship*: Dr. Nicolas Oeconomopoulos, University College, London. *Italian Fellowship*: Dr. Antonio Nasini, University of Cambridge. *Japanese Fellowship*: Dr. Kameyama, University College, London. *Norwegian Fellowship*: Mr. Leif Lindemann (provisional). *Spanish Fellowship*: Dr. Miguel Crespi, University College, London. *Swedish Fellowship*: Temporarily vacant. *Swiss Fellowship*: Dr. Walter Feitknecht, Royal School of Mines, London. The total value of the annual amount of the Fellowships that is awarded is approximately £4800, of which approximately £3300 is provided by grants from Dominion and foreign sources.

Mr. J. M. Mullaby, B.A., has been elected to a war memorial studentship in chemistry at Balliol College, Oxford.

With great regret we announce the death of Mr. J. T. Wood, former chairman of the Nottingham Section and a valued contributor to this Journal. He represented the British Section of the Society of Leather Trades Chemists on the Federal Council and was an indefatigable worker in the interests of chemical industry. An obituary will appear in a later issue.

We regret to announce the death of Sir Archibald Geikie, O.M., the doyen of British geology. He was one of the first field geologists in England to recognise the importance of microscopic investigation as as an adjunct to field work, and the author of several standard works.

The Electric Accumulator Regulations, 1924

The Home Office has published a draft of new Regulations under Section 79 of the Factory and Workshop Act, 1901, applying to the manufacture or repair of electric accumulators or parts thereof, containing lead in substitution for the Regulations made under the same section on November 21, 1903. Despite the operation of the existing Regulations, the incidence of lead poisoning among workers engaged in this industry has continued high. Thus, they are designed to extend the Regulations to cover to works in which accumulators are repaired as well as works where accumulators are manufactured. The requirements for securing the application of exhaust ventilation and the maintenance of cleanly conditions, have been strengthened so as to bring them up to the standard required in recent codes of Regulations for other industries where danger of lead poisoning occurs. The Regulations should be brought into force not later than January 1, 1925.

REVIEW

THE CONSTITUENTS OF COAL TAR. By P. E. SPIELMANN. Pp. xii+219. London: Longmans, Green and Co, 1924. Price 12s. 6d.

The author in his latest publication has set up before himself a high standard, and, as we should expect, has gone to great trouble to give his readers the wherewithal to search without difficulty for the origin of the information and data he provides.

The volume has for reference and convenience been divided into five parts. The four sections of Part I deal with tars as generally produced by varying methods of carbonisation. Part II deals with monocyclic and polycyclic compounds. The third part with the oxygen bodies, and the fourth with sulphur compounds. Nitrogen constituents form the last section, succeeded by the Bibliography notes and reference Indices. Two useful charts are inserted to help in estimating the purity of the Benzene fractions.

It is perhaps regrettable that a work on this subject should appear at a time in the history of the coal-tar industry when there is no desire evidenced on the part of those dealing with these products to separate the bodies which he describes. Many of the larger works are now preparing fewer of the special products and concentrating on material for roads.

How would such a book have been welcomed twenty years ago as a companion to the well-appreciated old friend "Lunge." On the other hand, it may be that the appearance of this volume will be a stimulus to the by-product industry, and induce it to attempt a greater variety of pure products, of which this book is in the nature of a "first aid." As the author states in his introduction, this book is for assistance, and does not pretend to be encyclopædic, and to the laboratory staff its great value will be unquestioned. Its appeal is manifestly to those with whom formulæ and their appurtenances, graphic and otherwise, are everyday routine, and a reasonably advanced knowledge of organic, inorganic and physical chemistry is taken for granted. The book contains wisely no reference to the ammoniacal compounds present in most tars. These might well form the subject matter of a further volume, and fairly come in another category.

The author might consider when further editions are called for a more extended article on the subject of pitch. It represents such a large bulk proportion of the constituents that one would have wished for more extended information, even if only the physical qualities and varying nature of the products from the different types of tar were noted. Take, for example, horizontal-retort tar pitch and that containing an abundant mineral matter such as is produced in blast-furnace practice. To dismiss the subject in a few lines seems regrettable.

The book is well written and printed, reflecting credit both on author and publisher, and it will be welcomed as a substantial addition to the libraries of gas and coke works, and also to those engaged in laboratories where the products described are dealt with.

ERNEST F. HOOPER

REPORTS

Report on the Finance, Industry, and Commerce of the United States of America. Dated April, 1924. By J. J. Broderick, H.M. Commercial Counsellor, Washington Department of Overseas Trade. Pp. 136. H.M. Stationery Office, 1924. Price 3s. 6d.

In introductory comments it is remarked how the nature of American trade is changing. Instead of catering for the home market and considering export merely an outlet for surplus production, industry is turning its attention more and more to foreign markets, whilst the import trade is increasing in a still more marked degree, increased imports of raw materials testifying to the growth of manufacturing activity since pre-war years. A Bureau of Foreign and Domestic Commerce has been working since 1913 with continually increasing activity in promoting export trade.

Since about 40 per cent. of the population is directly dependent on agriculture for a living, it is obvious that a period of depression in this industry has far-reaching effects. Such a depression marked 1920, and farmers are still in some measure suffering from it (*cf. Chem. and Ind.*, 1923, 663). Wheat prices at present are very low owing to decreased consumption and competition abroad from Argentina, Australia and Canada, whilst the cotton yield last year was disappointing in spite of the record acreage. The iron and steel industry had a very large output last year, 70,018,000 t. of iron ore being mined. The production of pig-iron, 40,200,000 t., was a record, and that of ingot-steel, 43,619,200 t., was 43 per cent. above the pre-war figure. The export trade, however, was slack and the excess of exports over imports of iron and steel goods continued the downward tendency which has been evident since 1920. In the coal industry 1923 was a year of large production and falling prices, output being estimated at 550 mill. t. against 408 mill. t. in 1922, and this was only partially relieved by increased exports which totalled 19 mill. t. as compared with 11 mill. t. In spite of a strike in the anthracite industry, which led to considerable imports from Britain, production was estimated at 95,650,000 t., 70 per cent. greater than in 1922 and almost a record. An over-estimate of the probable demand led to over-production in the petroleum industry early in 1923, and the effects of the consequent depression are only now showing signs of disappearing, though prospects are considered good. The output of electrical energy shows a continuous increase, being estimated at 66 billion kilowatt hours in 1923.

The copper mining industry has still to meet an unfavourable price situation, though an improvement is being shown in output, which reached 1467 mill. lb. last year, the total refinery production from all sources being 2110 mill. lb. The zinc, lead, and aluminium industries were more active, and magnesite mining has revived considerably. The production of various minerals has been encouraged by the taxation of imports, but in the graphite, chromite, and tungsten industries this course has not led to any progress. Sulphur production increased to 2,035,000 t., exports amounting to 472,525 t. Production and imports of pyrites in 1923 amounted to 181,628 t. and 260,000 t. respectively. Home production of potash is small, and the imports amounted to 231,000 t. The textiles industries had a good year, and the continued growth of the artificial silk industry is noteworthy.

Most branches of the chemical trade enjoyed a good year. Activity in the building trades led to record sales in the paint and varnish industries, whilst manufacturers of fertilisers emerged from a long period of depression. The question of nitrate supply has recently attracted Government attention with regard to the country's dependence on foreign supplies.

Physical and Chemical Survey of the National Coal Resources No. 3. The Lancashire Coalfield, the Arley Seam. Department of Scientific and Industrial Research, Fuel Research Board. Pp. vi+37. H.M. Stationery Office, 1924. Price 2s. 6d.

This Report gives the results of both laboratory tests and large scale operations on Arley coal (chosen because it is widely used), and embodies an account of experiments carried out with this coal by other workers. The coal is bituminous and strongly caking, and is largely employed both for gas making and in the manufacture of coke. For the preparation of metallurgical coke it is often best blended. It is also used for steam raising, and for household use, and is frequently sold blended with other seams. Analysis has proved the consistency of the seam throughout the greater part of the coalfield, and it would appear that the percentage of volatile matter in the coal substance is higher in the top sections, decreases towards the centre of the seam, and increases again at the bottom. This trend is also observable in the ash content, which varies in its composition and fusibility. The behaviour of the coal during carbonisation in the laboratory assay apparatus at a temperature of 600° C. has been studied and much useful information obtained on the general properties of the coal and the yields and qualities of the products. Carbonising tests at 600° C. have also been carried out in H.M. Fuel Research Station in the setting of mild steel horizontal retorts, specially designed for experimental work on low-temperature carbonisation. The results of these tests were in agreement with what might have been forecasted from the results of the laboratory assay. Tests on the steaming of Arley coal have also been carried out at H.M. Fuel Research Station in the setting of Glover-West vertical retorts on 400 tons of coal specially supplied for this purpose, and the main details of the several tests are given in the report. Further experiments and a complete microscopical examination of the seam in two different localities, have been made, and results indicate that the Arley seam is *especially* valuable for coal gas manufacture. From it metallurgical coke may also be made, and coal from certain localities is suitable for use by itself for low-temperature carbonisation, a strong, hard, compact, smokeless solid fuel being obtained. The yields of tar, gas, etc. in each case were satisfactory.

REPORT ON THE ECONOMIC AND FINANCIAL SITUATION OF EGYPT. DATED APRIL, 1924. By E. H. MULOCK, Commercial Secretary, Cairo. Department of Overseas Trade. Pp. 55. H.M. Stationery Office, 1924.

As the result of the successful working of the financial year 1923–4, the volume and favourable balance of trade in 1923, and the good prices obtained for the cotton crop during the year, Egypt is in a prosperous and economically satisfactory condition. Imports in 1923 were valued at £E45,270,941, about £E2 mill. more than in 1922 (*cf. Chem and Ind.*, 1923, 1118), whilst exports reached £E59,853,987, an increase of over £E8 mill. The increase in imports is chiefly accounted for by cotton piece goods, wheat flour, tea, sugar, and coal; decreases occurred in several categories including chemicals and tobacco. The chief articles of import are yarns and textiles, agricultural produce, wood and coal, metals and metal ware, chemical and medicinal products and spirits, beverages, and oils. The countries which mainly contributed to the increase were Italy, which now holds second place after the United Kingdom, Australia, New Zealand, India and other eastern British possessions, Palestine and Russia. The increase in exports is accounted for entirely by cotton, exports of which were valued at £E49,516,369 in 1923, though sugar, cottonseed and cottonseed oil also showed increases which offset decreases in benzine and agricultural products. The principal purchasers of cotton continued to be the United Kingdom and the United States, though France was not far below the latter. British purchases from Egypt were about one-half of the total.

The mining industries continued to show the effects of trade depression, but some signs of revival were apparent, for example, in the petroleum and manganese ore industries; phosphate production was, however, much curtailed.

LEGAL INTELLIGENCE

ALLEGED INFRINGEMENT OF LETTERS PATENT

Mr. Justice Tomlin, in the Chancery Division on October 30, gave judgment in an action by Dr. Meyer Wilderman against F. W. Berk & Co., Ltd., Fenchurch Avenue, E.C., for an injunction restraining them from, as he alleged, infringing his letters patent for an invention relating to "improvements in electrolytic cells for the electrolysis of alkaline salts."—(*Cf. Chem. & Ind.*, Oct. 24, 1924.)

His lordship said that in the process of manufacture used by the Deutsche Wilderman Werke there was employed a mechanical contrivance in the shape of a trough constructed with projections similar to what was contained in the plaintiff's specification. But it did not follow that the importation of potash made under these conditions was an infringement of the plaintiff's patent. He did not know what was the precise function of this contrivance in the making of electrolytic salts, because no evidence on the point was called. He could not think that the employment of, for instance, a patented blow-pipe or a patented hammer employed in the making of some part of a locomotive would necessarily render the locomotive an infringement of the patent. Each case must be determined on its merits, but in this case he did not think that the plaintiff had proved, and he (the judge) was not prepared to hold that the device which was the subject-matter of the invention was of such a character, or was so used in relation to the manufacture of potash, as to render the importation of the potash an infringement of the patent.

As to the plaintiff's right to sue, he held that the plaintiff could not, even if the alleged infringement was proved, maintain the action, because (1) at the date of the alleged infringement the patent was vested in the Custodian of Enemy Property owing to the fact that at that time the plaintiff was a "hostile person" within the meaning of the phrase as defined in the vesting order; (2) that there was nothing in the language of the vesting order which transferred the right of action to the plaintiff; (3) that under Article 309 of the Treaty of Peace, the plaintiff had acquired the character of a resident in Germany at the material date; and (4) that it had not been proved that the plaintiff had ever divested himself of that character.

He was satisfied that the defendants acted in good faith and were not aware of the existence of the patent. The action failed and must be dismissed with costs.

COMPANY NEWS

BRUNNER, MOND AND CO., LTD.

An interim dividend of 7 per cent., being the same rate as that declared a year ago, has been declared for the half-year ended September 30.

LASTENIA NITRATE CO.

At an extraordinary general meeting of the Compania Salitrera Lastenia (Lastenia Nitrate Co.) it was unanimously resolved to transfer assets and liabilities to the Lautaro Nitrate Co. as from October 31. The latter company will, therefore, take charge of the Compania Salitrera Lastenia business as from November 1.

ERINOID, LTD.

Speaking of the company's interests in France and the United States at the ninth annual meeting, the chairman said that the investment in the French company is slightly higher, owing partly to a loan which had been made to that company to provide for additional working capital. Business conditions during the past year in France had been difficult owing to the extreme flexibility of the exchange, but the French company was making a profit. Both the English and French companies are putting a new transparent material on the market for which there should be a large demand. As regards the Société Anonyme Foncière Erinoid, also a French company, the whole of the shares belong to Erinoid, which is

represented on the Board by the same directors as in Omnilith. All the necessary cash capital for the new company to be formed in connexion with the Casein Company of America will be found in the United States, and the allotted shares amount to $166,000, equal roughly to £33,000. The stocks of the company are all paid for, and the bulk of their requirements covered until next spring. The report and accounts were unanimously adopted.

BRITISH GOODRICH RUBBER CO.

A dividend at the rate of 7½ per cent. per annum on the preference shares has been declared, calculated from the dates for payments of instalments to November 30, 1924, less tax, payable on November 30.

GUEST, KEEN AND NETTLEFOLDS

The interim dividend is to be 5 per cent. for the six months ended September 30 on ordinary shares, free of tax, payable on December 19.

BRITISH AMERICAN NICKEL CO.

As the result of an action against the British American Nickel Co. by the National Trust Co. to protect the security of a $6,000,000 bond issue, the Court has ordered the former to be placed in liquidation with the latter. The liquidator's action is said to be an attempt to merge the properties in Quebec and Ontario in one block, all the company's assets being covered by the bond mortgage.

TRINIDAD LEASEHOLDS

The net profit for the year ended June 30 is £205,230 (against £133,240 in 1922–23). The total dividend for the year is 17½ per cent. against 10 per cent., whilst the "carry forward" is increased from £41,749 to £54,180. Capital expenditure during the year totalled £174,743 (against £97,351), of which £109,423 represented cost of well sinking (against £71,949). Working costs per ton were further reduced, whilst the production was 60,158 tons larger at 204,203 tons. Purchases from other companies declined by 886 tons to 122,911 tons. The amount written off for depreciation was £203,744 (against £157,084).

LIGHTING TRADES, LTD.

The trading profit for the year amounted to £12,000, against a trading loss for the previous year of £15,000, a distinct improvement. The closing and relinquishing of the lease of the Dartford factory has necessitated the writing-off of nearly £26,000, and exceptional expenditure of a non-recurrent nature was also inevitable during the year. During the period under review there had been a quantitative increase of 15 per cent. in sales. Continental competition is still very acute. The sale of products such as lamps, burners, glass, etc., has been conducted energetically with satisfactory results.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech. ..	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	.. £45 per ton.
Powder	.. £47 per ton.
Acid Hydrochloric	.. 3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	.. £21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric ..	.. Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali ..	.. £6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder	.. Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	.. £7 10s. per ton, packages extra.
Borax, Commercial—	
Crystal	.. £25 per ton.
Powder	.. £26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	.. £5 17s. 6d. per ton d/d.
Copper Sulphate ..	.. £25 per ton.
Methylated Spirit 64 o.p.—	
Industrial ..	.. 2s. 7d.—2s. 11d. per gallon, according to quantity.
Mineralised ..	.. 3s. 8d.—4s. per gallon, according to quantity.
Nickel Sulphate .. / Nickel Ammon. Sulphate	.. £38 per ton d/d. Normal business.
Potash Caustic ..	.. £30—£33 per ton.
Potass. Bichromate	.. 5⅜d. per lb.
Potass. Chlorate ..	.. 3d.—4d. per lb.
Salammoniac ..	.. £32 per ton d/d.
Salt Cake	.. £3 10s. per ton d/d.
Soda Caustic, solid	.. Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals ..	.. £5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	.. £24 per ton.
Sod. Bicarbonate	.. £10 10s. per ton, carr. paid.
Sod. Bichromate ..	.. 4½d. per lb.
Sod. Bisulphite Powder 60/62%	.. £17—£18 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate ..	.. 3d. per lb.
Sod. Nitrate refd. 96%	.. £13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst.	.. £9 per ton d/d.
Sod Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	6½d.—1s. 2d. per lb., according to quality.
Crimson	1s. 4d.—1s. 6d. per lb., according to quality.
Arsenic, Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide	£30—£33 per ton, according to quantity.
Carbon Black	7d.—7½d. per lb. ex wharf.
Carbon Tetrachloride	£60—£65 per ton, according to quantity, drums extra.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes White and Dark	5d.—9½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	£48 per ton, barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£16 5s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Precip. B.P.	£47 10s.—£52 10s. per ton, according to quantity.
Sulphur Chloride	4d. per lb., carboys extra.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep	5s. 1d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

There is a general feeling that the fall in price of acetates during the last few weeks has reached its limit. The tendency is now to stiffen again.

Acetate of Lime—	
Brown	£11 10s. per ton, and upwards.
Grey	£14 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Demand quiet but price steady.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 9d. per gall. Unrefined.
Wood Naphtha—	
Miscible	4s. 9d. per gall. 60% O.P.
Solvent	5s. per gall. 40% O.P. Firmer.
Wood Tar	£4—£5 per ton. Very quiet.
Brown Sugar of Lead	£41 per ton. Steady market.

TAR PRODUCTS

Acid Carbolic—	
Crystals	6½d. per lb. Quiet.
Crude 60's	1s. 8d.—1s. 10d. per gall. Market flat.
Acid Cresylic, 97/99	2s.—2s. 1d. per gall. Demand steady.
Pale 95%	1s. 8d.—2s. per gall. Not much enquiry.
Dark	1s. 8d.—1s. 10d. per gall. Market dull.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	6½d.—7½d. per gall. Small demand
Unstrained	6d.—6½d. per gall.
Benzole—	
Crude 65's	7½d.—9d. per gall. ex works in tank wagons.
Standard Motor	1s. 1½d.—1s. 3d. per gall. ex works in tank wagons.
Pure	1s. 5½d.—1s. 7d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5d.—1s. 6d. per gall. More inquiry.
Pure	1s. 7d.—1s. 9d. per gall. Small demand for home consumption.
Xylol—Coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	8d.—8½d. per gall. Little demand.
Middle Oil, Heavy Oil, Standard Specification	5½d.—6½d. per gall., according to quality and district. Fair business passing. A little more demand for export in bulk.
Naphtha—	
Solvent 90/160	1s. 3d.—1s. 4d. per gall. Demand good.
Solvent 90/190	11d—1s. per gall. Fair inquiry. Local demand good.
Naphthalene Crude—	
Cheaper in Yorkshire than Lancashire. Demand rather better.	
Drained Creosote Salts	£3—£5 per ton. Demand slightly better.
Whizzed or hot pressed	£6—£9 per ton. Demand very poor.
Naphthalene—	
Crystals and Flaked	£12—£15 per ton, according to district.
Pitch, medium soft	42s. 6d.—60s. per ton according to district. Plenty of inquiry. Prospects brighter.
Pyridine—90/160	19s. per gall. Steady demand.
Heavy	11s.—12s. per gall. Market dull.

INTERMEDIATES AND DYES

Business in dyestuffs has been very well maintained this week.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 7d. per lb.
Acid H.	3s. 11d. per lb. 100% basis d/d.
Acid Naphthionic	2s. 2d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 1d. per lb. Improved demand.
Acid Sulphanilic	9d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	8d. per lb. naked at works.
Aniline Salts	8½d. per lb., naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	3s. 11d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 1d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C.	4d.—4½d. per lb. Rather quiet.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	3s. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£85 per ton.
Diethylaniline	4s. 3d. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 2½d. per lb. d/d. Drums extra.
G. Salt.	2s. 4d. per lb. 100% basis d/d.
α-Naphthol	2s. 5d. per lb. d/d.
Dinitrobenzene	9d.—10d. per lb. naked at works.
Dinitrochlorbenzol	£84 10s. per ton d/d.

Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine ..	.. 2s. 10d. per lb. d/d.
Monochlorbenzol..	.. £63 per ton.
β-Naphthol ..	.. 1s. per lb. d/d.
α-Naphthylamine	.. 1s. 3½d. per lb. d/d.
β-Naphthylamine	.. 4s. per lb. d/d
m-Nitraniline ..	.. 4s. 2½d. per lb. d/d.
p-Nitraniline ..	.. 2s. 2½d. per lb. d/d.
Nitrobenzene ..	.. 5½d.—5¾d. per lb. naked at works.
o-Nitrochlorbenzol	.. 2s. 11d. per lb. 100% basis d/d.
Nitronaphthalene	.. 10½d. per lb. d/d.
p-Nitrophenol ..	.. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	.. 3s. 10d. per lb. d/d.
p-Phenylene Diamine	.. 10s. 2d. per lb. 100% basis d/d.
R. Salt	.. 2s. 4d. per lb. 100% basis d/d.
Sodium Naphthionate	.. 2s. 2d. per lb. 100% basis d/d.
o-Toluidine ..	.. 10d. per lb.
p-Toluidine ..	.. 3s. per lb. naked at works.
m-Toluylene Diamine	.. 3s. 10d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	.. £45 per ton, ex wharf London, in glass containers.
Acid, Acetyl Salicylic	.. 3s. 1d.—3s. 3d. per lb., according to quantity. Sales steady. Price firm.
Acid, Benzoic B.P.	.. 2s. 6d. per lb.
Acid Boric B.P. ..	.. Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric..	.. 19s.—21s. per lb.
Acid, Citric ..	.. 1s. 4d. per lb., less 5% for ton lots. Market still weak.
Acid, Gallic ..	.. 2s. 9d. per lb. for pure crystal in 2 cwt. lots.
Acid, Pyrogallic, Cryst.	.. 6s. 9d. per lb. Resublimed quality 8s. per lb. Market firm.
Acid Salicylic	.. 1s. 6d.—1s. 8d. per lb., according to quantity. Slightly firmer.
Acid, Tannic B.P.	.. 2s. 10d. per lb. Forward quotations higher spot value likely to increase.
Acid, Tartaric ..	.. 1s. per lb., less 5%.
Amidol	.. 9s. per lb. d/d.
Acetanilide ..	.. 1s. 10d.—2s. per lb. More enquiry.
Amidopyrin ..	.. 15s. per lb.
Ammon. Benzoate	.. 3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	.. 12s. 6d. per oz. for English make.
Barbitone.. ..	.. 13s. 9d. per lb. Slightly lower. Quiet steady demand.
Benzonaphthol ..	.. 5s. 3d. per lb. spot.
Bismuth Carbonate	.. 10s. 6d.—12s. 6d. per lb.
„ Citrate..	.. 10s. 3d.—12s. 3d. „
„ Salicylate	.. 9s.—11s. „
„ Subnitrate	.. 8s. 8d.—10s. 8d. „
Borax B.P. ..	.. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	.. Market exceedingly firm and prices advancing. Raw materials dearer. British prices lower than foreign.
Ammonium ..	.. 1s. 11d. per lb.
Potassium ..	.. 1s. 9d. per lb.
Sodium ..	.. 1s. 10d. per lb.
Calcium Lactate	.. 1s. 7d.—2s. per lb., according to quantity. Fair demand and steady market.
Chloral Hydrate ..	.. 4s. per lb.
Chloroform ..	.. 2s. 6d. per lb. for cwt. lots.
Formaldehyde ..	.. £48—£49 per ton in barrels, ex wharf London.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free ..	.. 7s. per lb.
Glycerophosphates—	
Iron	.. 8s. 9d. per lb.
Magnesium ..	.. 9s. per lb.
Potassium, 50%	.. 3s. 6d. per lb.
Sodium, 50% ..	.. 2s. 6d. „
Guaiacol Carbonate	.. 9s. 9d. per lb.
Hexamine	.. 3s. per lb. Forward prices higher.
Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor	.. English make offered, 120s. per oz.
Hypophosphites—	
Calcium ..	.. 3s. 6d. per lb., for 28-lb. lots.
Potassium ..	.. 4s. 1d. per lb.
Sodium ..	.. 4s. „
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb.
Magnesium Carbonate—	
Light Commercial	.. £36 per ton net.
Magnesium Oxide—	
Light Commercial	.. £75 per ton, less 2½%.
Heavy Commercial	.. £25 per ton, less 2½%.
Heavy Pure ..	.. 2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	.. 60s. per lb. for December delivery. No spot deliveries available.
Synthetic ..	.. 26s.—35s. per lb., according to quantity. English make. Increasing demand.
Mercurials ..	.. Market very quiet.
Red oxide ..	.. 5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	.. 3s. 6d.—3s. 7d. „
White precip. ..	.. 4s. 7d.—4s. 8d. „
Calomel ..	.. 3s. 11d.—4s. „
Methyl Salicylate	.. 1s. 10d. —2s. per lb.
Methyl Sulphonal	.. 22s. 6d. per lb. Slightly weaker.
Metol	.. 11s. per lb. British make.
Paraformaldehyde	.. 2s. 8d. per lb. for B.P. quality.
Paraldehyde ..	.. 1s. 4½d.—1s. 6d. per lb. in free bottles and cases. Supplies plentiful.
Phenacetin ..	.. 5s. 6d. per lb.
Phenazone ..	.. 7s. per lb.
Phenolphthalein ..	.. 5s. 6d. per lb. for cwt. lots. Supply exceeds demand.
Potass. Bitartrate—99/100% (Cream of Tartar) ..	.. 84s. per cwt., less 2½% for ton lots.
Potass. Citrate ..	.. 1s. 10d.—2s. 2d. per lb.
Potass. Ferricyanide	.. 1s. 9d. per lb. Quiet.
Potass. Iodide ..	.. 16s. 8d.—17s. 5d. per lb., according to quantity. Steady market.
Potass. Metabisulphite	.. 7½d. per lb., 1-cwt. kegs included. F.o.r. London.
Potass. Permanganate	.. 7½d. per lb. spot. Forward prices higher.
Quinine Sulphate	.. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	.. 5s. 3d. per lb.
Saccharin ..	.. 63s. per lb., in 50-lb. lots.
Salol	.. 3s. 9d. per lb. for cwt. lots.
Silver Proteinate..	.. 9s. per lb. for satisfactory product, light in colour.
Sod. Benzoate, B.P.	.. 2s. 6d. per lb. Supplies of good quality now available.

Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite—	
Photographic ..	.. £13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash. according to quantity.
Sod. Nitroprusside ..	16s. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	.. 75s.—82s. 6d. per cwt., according to quantity. Quiet market.
Sod. Salicylate ..	.. Fair demand. Powder 2s.—2s. 3d. per lb. Crystal at 2s. 2d.—2s. 5d. per lb. Flake 2s. 6d. per lb.
Sod. Sulphide—	
Pure recryst. ..	.. 10d.—1s. 2d. per lb.
Sod. Sulphite, anhydrous	£27 10s. per ton, minimum 5-ton lots, increasing according to quantity, 1-cwt. kegs included.
Sulphonal.. ..	.. 14s. 6d. per lb. Little demand.
Thymol	.. 16s. 9d. per lb. Firmer market.

PERFUMERY CHEMICALS

Acetophenone ..	.. 12s. per lb.	
Aubepine	.. 15s. 3d. ,,	
Amyl Acetate ..	.. 2s. 9d. ,,	
Amyl Butyrate ..	.. 6s. 9d. ,,	
Amyl Salicylate ..	.. 3s. 3d. ,,

Sandal Wood Oil—	
Mysore	.. 26s. 7d. per lb.
Australian ..	.. 18s. 6d. per lb.

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition not later than January 5th, they are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on November 20th.

I.—Applications

Carpmael (Farbenfabriken vorm. F. Bayer und Co.). Means for letting off steam from a container. 25,699, 25,700. Oct. 28.

Carpmael (Farbenfabriken vorm. F. Bayer und Co.). Means for running off hot liquids from a container under pressure. 25,701. Oct. 28.

Cross. Refining-materials. 25,525. Oct. 27. (U.S., 31.12.23.)

Eggenhöffner. Manufacture of pulverised substances. 25,681. Oct. 28.

Fuller-Lehigh Co. Furnace. 25,532. Oct. 27. (U.S., 27.10.23.)

Remfry. Purification of liquids. 25,530. Oct. 27.

Smith. Filtering tanks. 25,703. Oct. 28.

Underfeed Stoker Co., Ltd., and Wood. Pulverising and drying of materials. 25,603. Oct. 27.

I.—Complete Specifications Accepted

16,255 (1923). Fulcher and Beldam. Straining or filtering apparatus. (223,627.)

9767 (1924). Ostermann, Sudenburger Maschinenfabrik und Eisingiesserei Akt.-Ges. Mechanical production of colloidal substances. (216,110.)

19,408 (1924). Pintsch Akt.-Ges. *See* II.

II.—Applications

Greenfield. Method of dephlegmation in steam distillation of oils. 25,505. Oct. 27.

Koppers Co. Coking retort ovens. 25,794. Oct. 29. (U.S., 4.1.24.)

Lucas, and V. L. Oil Processes, Ltd. Cracking and separating mineral oils. 25,986. Oct. 31.

II.—Complete Specifications Accepted

13,648 (1923). Illingworth, and Illingworth Carbonization Co., Ltd. Manufacture of carbonised fuel. (223,624.)

19,016 (1923). Pell. Retort apparatus for treating shale, coal, and the like. (223,652.)

19,091 (1923). De Laval Chadburn Co., Ltd., and Johnstone. Centrifugal separators for dehydrating or otherwise purifying oil. (232,656.)

29,890 (1923). Underfeed Stoker Co., Ltd., and Wood. Drying and pulverising fuel. (223,764.)

19,408 (1924). Pintsch Akt.-Ges. Porous charges for containers for the storage of acetylene or like gases dissolved in liquids. (220,645.)

III.—Application

Montgomerie. Production of tar bitumen emulsions. 25,628. Oct. 28.

IV.—Applications

Farbwerke vorm. Meister, Lucius, und Brüning. Manufacture of Bz-2'-oxybenzanthrones. 25,597. Oct. 27. (Ger., 9.11.23.)

Morton Sundour Fabrics, Ltd., Harris, Jones, and Morton. Dyes and dyeing. 26,086. Nov. 1.

Scottish Dyes, Ltd., Smith, Thomas, and Wylam. Colouring-matters. 25,550. Oct. 27.

Sokal (Kalle und Co., Akt.-Ges.). Process for producing sulphur dyestuffs fast to chlorine. 26,091. Nov. 1.

IV.—Complete Specifications Accepted

25,043 (1923). Soc. of Chemical Industry in Basle. Manufacture of naphthalene derivatives and of dyestuffs therefrom. (207,162.)

2378 (1924). Durand und Huguenin Akt.-Ges. Manufacture of disazo-dyestuffs. (210,463.)

V.—Applications

Dreaper. Manufacture of artificial silk etc. 25,491. Oct. 27.

Ellis (Kohnstamm and Co.). Treatment of textile materials. 25,895. Oct. 30.

Heys, and St. Anne's Board Mill Co. Apparatus for removing liquid from paper pulp etc. 25,878. Oct. 30.

Kennedy. Treating paper stock. 25,637. Oct. 28. (U.S., 15.12.23.)

Naylor. Treating fibrous vegetable waste. 25,668. Oct. 28.

V.—Complete Specifications Accepted

11,226 (1923). Kanegafuchi Boseki Kabushiki Kwaisha. Treatment of raw silk. (196,923.)

11,775 (1924). Bergen. Manufacture of threads etc. from viscose. (216,125.)

16,742 (1924). Akt.-Ges. für Anilin-Fabrikation. Manufacture of viscose products. (220,935.)

VI.—Applications

Brandwood. Treatment of yarns with fluids. 25,616. Oct. 28.

Calico Printers' Association, Ltd., and Gemmell. Machines for wet treatment of textile fabrics. 25,672. Oct. 28.

Morton Sundour Fabrics, Ltd., Harris, Jones, and Morton. 26,086. *See* IV.

VII.—Applications

Assoev. Production of aluminium compounds. 26,012. Oct. 31. (Belgium, 21.11.23.)

Soc. Anon. d'Eclairage et d'Applications Electriques. Process for separating krypton and xenon from the atmosphere. 25,715. Oct. 28 (Fr., 26.12.23.)

Soc. l'Air Liquide, Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude. Manufacture of hydrogen. 25,995. Oct. 31. (Fr., 15.5.24.)

VII.—Complete Specification Accepted

4967 (1924). Jahl and Michael. Production of soluble barium salts. (223,800.)

VIII.—Complete Specifications Accepted

10,893 (1923). Duffield. Manufacture of refractory bricks, blocks, or the like from dolomite etc. (223,616.)

14,532 (1924). General Electric Co., Ltd. Readily fusible glasses and enamels. (223,837.)

IX.—Applications

Cyclops Building and Construction Co., Ltd., and Rigby. Induration of concrete. 25,641. Oct. 28.

Douzal. Artificial wood. 25,546. Oct. 27. (Fr., 12.1.24.)

Kirkpatrick. Composition for surfacing roads etc. 26,029. Nov. 1.

Lee. Manufacture of cement. 25,625. Oct. 28.

Montgomerie. 25,628. *See* III.

IX.—Complete Specifications Accepted

22,832 (1923). Bayer. Manufacture of porous building-materials. (203,718.)

28,296 (1923). Soc. Anon. des Chaux et Ciments de Lafarge et du Teil. Manufacture of fused cement. (222,426.)

28,297 (1923). Soc. Anon. des Chaux et Ciments de Lafarge et du Teil. Apparatus for the manufacture of cement by fusion. (222,427.)

X.—Applications

Compagnie Générale des Produits Chimiques des Louvres. Mechanical roasting of ore. 25,799. Oct. 29. (Fr., 30.10.23.)

Landling. Aluminium alloy. 25,639. Oct. 28.

Maas. Treatment of metals. 25,792. Oct. 29.

Metals Production, Ltd., Moulden, and Taplin. Heat treatment of oxidised copper ores. 25,816. Oct. 29.

Sollis. Aluminium alloy. 25,639. Oct. 28.

Voos. Utilising metalliferous refuse. 25,934. Oct. 30.

X.—Complete Specifications Accepted

34,760 (1922). Grah. Process for the electrodeposition of chromium. (223,611.)

11,082 (1923). Borchers and Stimson. Purification of alloys containing iron and chromium, molybdenum, or uranium. (223,617.)

11,389 (1923). Borchers and Stimson. Production of alloys containing iron and chromium, molybdenum, or uranium. (223,622.)

16,068 (1923). Hyde and Turner. Manufacture of iron manganese alloys. (223,626.)

24,912 (1923). Comp. des Forges de Chatillon Commentry et Neuves-Maisons. Thermic treatment of steel and alloys susceptible of tempering. (211,441.)

26 872 (1923). Fassotte, and Comp. des Metaux Overpeltlommel. Roasting ores. (223,741.)

438 (1924). General Motor Research Corporation. Alloy articles. (216,484.)

XI.—Applications

Collino. Electrolytic cells. 25,828. Oct. 29. (Italy, 22.11.23.)

Holmboe. Electrodes for electrolytic decomposition apparatus. 25,819. Oct. 29.

Kirkaldy. Electrodes. 25,880. Oct. 30. (U.S., 30.10.23.)

Markiewicz and Römer. Dry cells or batteries. 26,017. Oct. 31.

XI.—Complete Specifications Accepted

34,760 (1922). Grah. *See* X.

18,883 (1923). Western Electric Co., Ltd. (Western Electric Co., Inc.). Electric insulating-materials. (223,644.)

25,707 (1923). Pouchain. Electrolyte for electric accumulators. (205,517.)

XIII.—Complete Specifications Accepted

18,586 (1923). Tarassoff. Production of resin-like condensation products. (223,636.)

30,585 (1923). McLean. Manufacture of resinous or like preparations. (209,720.)

XV.—Application

Jordan. Tanning leather. 25,982. Oct. 31.

XV.—Complete Specification Accepted

11,361 (1923). Nance. Tanning. (223,621.)

XVI.—Application

Stötzel. Production of manure. 25,585. Oct. 27. (Ger., 3.11.23.)

XVIII.—Application

Rigby. Products containing yeast preparations. 26,024. Nov. 1.

XIX.—Application

Zpovak. Manufacture of meat substitutes etc. 25,685. Oct. 28.

XX.—Application

Binz and Räth. Production of heterocyclic compounds. 25,935. Oct. 30.

IX.—Complete Specifications Accepted

19,012 (1923). Nederlandsche Gist- en Spiritusfabriek. Producing a non-peroxidising ether. (219,272.)

19,026 (1923). Nederlandsche Gist- en Spiritusfabriek. Process of producing chemically-pure, toxic free, narcotising ether. (219,273.)

2276 (1924). Chemosan Akt.-Ges. Production of solutions of mercury derivatives of hydroxysulphobenzoic acids and their homologues, suitable for use in therapeutics. (215,316.)

XXI.—Application

Liesegang, and Rotopulsor A.-G. Photographic gelatin layers. 25,579. Oct. 27. (Ger., 26.10.23.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following inquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number:—*Argentina*: Artificial silk yarns, (497); *Belgium*: Ammonium carbonate, (487); *British India*: Paints, (India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E. 1); Iron and Steel (Directors of the Madras and Mahratta Railway Company, Ltd., 25, Buckingham Palace Road, London, S.W. 1); *Canada*: Hardware, (481); *Cuba*: Linseed oil, (499); *Egypt*: Iron, lead, brass, copper, rubber, hardware, oils, (495); *France*: Copper sulphate, (488); *Norway*: Leather, (493); *South Africa*: Hardware, (482); Metals, ores, (484); *United States*; China clay, (496), Paper, (B.X./1304), Leather, (B.X./1314).

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the Dyestuffs (Import Regulation) Act, 1920, made during October, has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee. The total number of applications received during the month was 543, of which 452 were from merchants or importers. To these should be added 25 cases outstanding on October 1, making a total for the month of 568. These were dealt with as follows:—Granted, 424 (of which 378 were dealt with within seven days of receipt); referred to British makers of similar products, 96 (of which 73 were dealt with within seven days of receipt); referred to Reparation Supplies available, 36 (all dealt with within two days of receipt); outstanding on October 31, 1924, 12. Of the total of 568 applications received, 487 or 86 per cent. were dealt with within seven days of receipt.

Amalgamation of German Dye Agencies in Japan

Owing to the new requirements for licences for the importation of dyestuffs into Japan, the selling agencies of all the German dye manufacturers in Japan have formed a joint distributing agency, comprising a manager, five commercial directors, two technical directors, and two directors specialising in sales of indigo. All the different laboratories will now be merged in one large central laboratory, staffed by fifteen German chemists, and over one hundred Japanese technical men. It is not known whether other chemical products will be included in the amalgamation.

The Danish Chemical Market

There is a good market for chemicals in Denmark, as the greater part of the supplies has to be imported. The chief consuming industries are soap, oils and fats, soda, paint and varnish, matches, fertilisers, textiles and leather. Imports of the chief chemicals in 1922 were as follows:—Soda ash, 12,172 tons (1923); hydrochloric acid, 1567 t.; sulphuric acid, 1100 t.; tanning extracts, 2340 t.; alum, 760 t.; chloride of lime, 400 t.; rosin, 1250 t.; raw phosphate, 100,000 t. Germany is the chief source of imported chemicals, followed by England, Belgium, and Sweden in the order named.—(*U.S. Com. Rep., Oct.* 6, 1924).

Glass Industry in Czechoslovakia

Conditions continue favourable in the glass industry of Czechoslovakia and exports to America and Great Britain remain at a high level, but there is a tendency to develop the home industry and to become independent of imports. Belgian competition is also being felt. England re-exports Czechoslovakian glass to Canada, South America and to China, but the Chinese market has of late become dull, enormous quantities of glass purchased by Chinese dealers after the Japanese earthquake having actually been sold at a loss. The hollow glass trade is now working at 60 per cent. of pre-war capacity, owing to the volume of business with England, Japan and the United States. The manufacture of bottles is reported as being 50 per cent. larger than last year.

Trade Notes from Canada

The exports of Canada to Germany have increased from \$5,735,268 for the twelve months ending August 31, 1922, to \$11,557,950 in the succeeding twelve months, and to \$17,755,519 in the year ending August 31 last. Imports from Germany have also increased during these periods respectively, as follows: \$1,933,030, \$3,928,991, and \$5,986,732. The leading commodities sold by Canada to Germany during the past year were flour, grain, automobiles, nickel and asbestos. The principal imports were incandescent lamps, toys, dyestuffs and tanning material, cacao butter, porcelain, cutlery, glass and textiles.

The maple sugar and syrup production of Canada for 1924 is valued at slightly under \$6,000,000, of which slightly over \$4,000,000 is credited to Quebec.

The sugar beet crop of Western Ontario is the largest on record. The refineries at Chatham and Wallaceburg, Ontario, are operating.

The Quebec Rubber Company is erecting a plant for the manufacture of rubber goods in Quebec city.

Foreign Company News

La Société des Produits Chimiques et Electrométallurgiques d'Alais, Froges et Camargue is negotiating with the French Government for the installation at the Toulouse Powder Factory of plant to produce 120 metric tons of synthetic ammonia by the Casale

process, of which the company holds the French rights. The Toulouse Powder Factory is now being utilised, as we have already announced, by the Office National Industriel de l'Azote, a plant for the synthesis of ammonia by the Haber Process being in course of installation, as a sequel to the vote of the French Parliament ratifying the agreement with the Badische Anilin und Soda Fabrik.

The Société Alsacienne de Produits Chimiques has purchased a process for the synthesis of hydrocarbons, with the object of contributing to the national production of fuel. The patent belongs to a company which provided practically the whole of the fuel for heavy transport in Germany during the war.

The Société des Charbonnages de Millam, which owns large deposits of lignite, is studying the distillation of lignites. New distillation plant are being erected for the production of tar, benzol and other by-products.

The Société Alsacienne de produits chemiques has recommenced the manufacture of synthetic camphor at its Vaugoin works near La Rochelle, which has been suspended for two years.

The Cie. Belge pour les Industries chimiques made a profit of 2,213,674 francs during the last working year, compared with 1,543,232 francs during the preceding year. The dividend is 10 francs., against 7·50 francs.

Notes on Plant and Products

Colour makes a universal appeal, and one of the first duties of the manufacturer who produces it is to see not only that it matches perfectly, but that it is reasonably resistant upon exposure to light. Until recently the only way of testing the fastness of a colour was to expose a dyed sample on a roof or facing a southern light, or to some kind of "artificial daylight," methods which were open to objection on the grounds of slowness if not of reliability. The most recent device for testing the fastness of colour is the "Fade-Ometer," an application of the violet carbon arc which has been developed as a means of giving definite, quantitative information on the fastness of colour to light because it possesses "the maximum speed of operation" whilst "retaining the all-important property of similarity to sunlight in fading quality." Messrs. A. D. Lang, Ltd., of 42, Berners Street, London, W. 1., who possess a most interesting series of tests carried out for various firms showing the standard nature of the results obtained with the Fade-Ometer, furnish another valuable aid to the colour maker and user in the Macbeth Colour Identification and Macbeth Daylight Lamps, which are used to give high illumination for critical examination of colours. No attempt is made to "standardise" the ever-varying daylight, but a series of colour filters is provided which enables any daylight equivalent to be utilised. The Macbeth lamps have received approval from the National Physical Laboratory for colour matching and colour identification, and their use is constantly [illegible].

VOL. 43 NEW SERIES | LONDON, NOVEMBER 21, 1924 | NO. 47

EDITORIAL

THERE is no doubt that the Chemical Industry Dinner was a great success. It was no mere dinner; it was a banquet of which any society or aggregate of societies would have been proud. The speeches, briefly reported in cold print, lose their charm and their sparkle; some of Mr. Coley's remarks had a curious felicity which was delightful; we wish we could reproduce more of Dr. Cullen's speech and could adequately thank Mr. Percy Ashley for his flattering observations about our journal. Sir Richard Glazebrook, Mr. Woolcock and most of the other speakers testified to the growing feeling of co-operation and united among chemists and industrialists. For this we think the Society of Chemical Industry and the Chemical Industry Club are entitled to the bulk of the credit. Circumstances have also helped them; a generation or so ago, chemists were so few and so scattered that it was impossible to create a standard of chemical public opinion. To-day this exists; it is true it is in its infancy, but the observant may watch it growing and taking shape. We have ourselves witnessed many of the significant steps: in industry, the growth of Brunner Mond and Co. and their allied companies; the fusion of interests which led to the prosperity of the United Alkali Company; the fusion which has formed the British Dyestuffs Corporation, not yet a complete success commercially but destined to become so; the formation of the Association of British Chemical Manufacturers; in science we have seen the Federal Council and the Bureau of Chemical Abstracts; on the social side, the Club. Each of these events or organisations has had its effect, and so have others we have not mentioned, and the effect tends to greater efficiency, greater service to industry and to science, a widening of interest on the part of all those who are in any way concerned in science. Without such influences as these, the chemical exhibit at Wembley and Chemistry in the XXth Century would have been of much less importance; these also are stepping stones to higher things. There is a real and definite advance going on in the profession and industry of chemistry. Each one of us can do so little; but if we all do what little is in our power how much will be accomplished! Probably, one of the next stages in the march of chemistry should be the much-discussed scheme of a Chemistry House. Addison said: "'Tis not in mortals to command success, but we'll do more, Sempronius, we'll deserve it." If chemists deserve Chemistry House, they will get it.

* * *

Really, we ought to know better than to quote poetry; it is apt to be misunderstood. If in our youth we had known what was in store for us we should probably have carefully treasured some odd phrases of Dumas, of Williamson, Frankland and Berzelius, and these would now come naturally into our minds whenever we took a pen or pencil in hand. Alas! regardless of their doom, the little victims play! In those tender and impressionable years we were permitted, and even encouraged, by our thoughtless parents to read as much English literature as we wished, far more than we could understand, but not more than we could enjoy. We shall, we fear, never quite free ourselves from the taint; the wool once dipped in the dye never regains its lost hue. Poetry is sometimes looked upon with suspicion; the grave amongst us think it is, perhaps, undignified. Some chemists who sat near us at the dinner objected quite definitely to a lapse on the part of the Club Secretary who quoted two lines about the presence of ladies. We think Mr. Williams would have been wiser if he had avoided such dangerous ground. Our critical friends found fault with Mr. Williams for quoting poetry at all, and especially poetry of such poor quality. And yet Milton was once regarded as one of our best poets, and "L'Allegro" as one of his most beautiful and popular effusions. Had he but known how fastidious modern chemists are in their literary tastes he would, we are sure, have been more careful. But it is probably too late now to alter his poems so as to make them more acceptable to modern minds and modern scientific erudition. We must put up with them as they are and Mr. Williams and ourselves

may learn wisdom, as others do, by making experiments and noting the results.

* * *

In mathematics there exists an infinite gradation between zero and any given number; in politics there is every variety of opinion between the most stereotyped Die-hard who believes that every institution which is old is necessarily good, and the Bolshevist who believes that every institution which is old is necessarily bad. So, too, in the great field of human knowledge; the various sciences pass imperceptibly into each other. The differences between the English language, the Dutch, Flemish, Frisian, Danish and Swedish are bridged by intermediate dialects. Mathematics, Physics, Chemistry and Engineering are not isolated subjects, but each has points of contact with all the others. Biology, Agriculture, Chemistry and Medicine are equally closely related, and no one can have a real knowledge of any one science who does not realise the points of contact, the common ground, the interdependence of many important branches of the one subject on many points in the others. Whether Sir Ernest Rutherford considers himself a chemist is of no consequence; he claims he knows no chemistry and he ought to know. But he knows that the work he has done has thrown an immense amount of light on all the conceptions of chemical elements and chemical action which are of fundamental importance. Chemistry can advance but slowly without the help of our Rutherfords, Moseleys and Astons. The opening of the Ramsay Laboratory of Chemical Engineering is a significant fact in the better understanding of science. Chemistry, Physics and Engineering have, in chemical industry, an intimate relationship; there must be a numerous band of men who have an adequate knowledge of the main essentials of these three subjects. In some, chemistry will predominate; in others, physics or engineering. The chemical engineer may differ in his mode of life and mode of thought from the chemist and from the civil engineer, but he is essential to our development, and he has come to stay. In these circumstances it is essential that he shall have the best facilities for his theoretical education in places where subjects are taught with the accuracy which is expected in a modern university. His practical education, we presume—for we do not profess to know—he will learn by experience, often bitter, and by the exercise of his wits and common sense, that is assuming——. At South Kensington and at University College he will have the best opportunity of getting his theoretical knowledge and making experiments. The new Laboratory at University College represents the highest educational advance in chemical engineering, and should prove of great importance to chemical industry. The opening was performed by H.R.H. Prince Arthur of Connaught, and was approved by the Chief Government Chemist, the President of the Society of Chemical Industry, by the new Professor of Chemical Engineering, Prof. Williams, by the Chairman of University College, and by the Chairman of Messrs. Brunner Mond and Co., Ltd., a combination of social, academic, scientific, and industrial influence which will be of the utmost value to the new Chair.

CRUSHING AND GRINDING.—PART I

By S. G. URE, M.A., B.Sc., M.I.Chem.E.

The subdivision of solids forms an important pa in many industrial processes, and as the mat rials to be reduced vary considerably, a very lar number of different machines have been invent for the purpose. Subdivision may be employed increase the surface and so cause a chemical reacti to be completed in the minimum time, or, if the bo being broken is non-homogeneous, to detach one co stituent from another and so permit of their separ tion, or to produce a saleable commodity. The r duction in size may be effected by the application a compressive or crushing force, as in the jaw type crusher, or a shearing force, as in machines of tl grinding or attrition type. Many machines such those of the roll, hammer, and impact types mal simultaneous use of those forces to reduce the size the material fed into the machine. In another ty beam action is employed, the force being applied an unsupported point in the material between tl two fixed points upon which it rests.

Since there is such a variety of crushing an grinding machinery to choose from, the selection the proper machine requires a knowledge of th physical properties such as the hardness, structu and moisture content of the material to be sul divided. The first of these factors affects not onl the strength and the speed of the machine, but als governs the use of special devices to protect th wearing parts from abrasive action. The structure o the material must also be taken into account, a machines which could easily reduce a brittle materia might be totally incapable of handling a fibrous o soft substance. Again, as it has been found tha materials containing above 5 per cent. and under 5 per cent. of moisture form a pasty mass which, whe the particles are reduced to the proper size, prevent them falling freely from the machine, to ensur efficiency this point must receive attention in th design or selection of the machine.

Other important conditions which must be remembered during selection are, the size of the pieces to b fed into the machine, as will be seen later in the discussion on the areas of the opening of the jaw an gyratory crushers, and the size of the product whicl is desired. In some cases the production of fine particles is the object in view, whilst in other cases thes fine particles are undesirable and have to be removed before the crushed product can be passed on to the next stage of the process. One must also know the amount of material to be treated per day and any special conditions under which the machine may have to work or relating to its transport to the site.

The purchase of a satisfactory machine will, therefore, be best ensured by submitting a representative sample of the material to be crushed or ground, together with full information regarding the output required and the conditions under which the machine will have to work to makers of plant of this type, so that they may be able to obtain accurate information regarding capacity, output per hour, and power required for driving the machine as well as other points influencing the design and efficient working.

The two laws connecting the energy required and the sizes of the material before and after subdivision are known as Rittinger's law and Kick's law. The former assumes that the new surface produced during the process of crushing or grinding is a measure of the energy consumed in the process, the subdivision of the material being produced by the application of a shearing stress. Practical results show that the amount of work done compared with the area of fractured surface is constant for coarse sizes, but the amount of new surface produced in fine grinding is greater than the energy required by the above law. This is attributed to the possibility of the production of incipient fractures during the coarse crushing stage. Rittinger's law expressed mathematically takes the form—

$$H = C\left(\frac{1}{d_2} - \frac{1}{d_1}\right)$$

where H = power required, d_1 the diameter or linear dimensions of the pieces of material fed into the machine, d_2 the diameter or linear dimensions of the product obtained, and C a constant which is dependent upon the material. Kick's law states that equal amounts of energy are required for the reduction of equal quantities of material through the same reduction range. It is based on the assumption that direct pressure of constant amount per unit area is applied to subdivide each particle which breaks up into smaller particles of similar shape. This law may be written

$$H = b \log \frac{d_1}{d_2}$$

where H represents the power required, d_1 and d_2 the diameters or linear dimensions of the particles entering and leaving the machine respectively, and b is another constant, which must be determined experimentally as it depends on the type of machine and the material which is being crushed. Accurate facts are not represented by either of these laws, and it is possible that when a satisfactory expression is developed it will lie between the two. Some writers divide machinery of this type into three classes—breakers, crushers, and grinders—whilst others adopt four classes. Preliminary crushers or breakers which can crush material varying in size from 2 to 60 ins. belong to the first class, whilst if the feed consists of pieces ranging between $1\frac{1}{2}$ and 2 ins., the machine is placed in the second group. The limits of the size of particles admitted to fine crushers are from $1\frac{1}{2}$ to $\frac{1}{2}$ in. and the product must be capable of passing through a 10-mesh screen. The last class, termed fine pulverisers, are supplied with material varying from $\frac{1}{2}$ to $\frac{1}{4}$ in., and are able to produce a product which can pass through a 200-mesh screen.

Jaw Crushers

Many well-known engineering firms, such as Edgar Allen and Co., Ltd., The Fraser and Chalmers Engineering Works of the General Electric Co., Ltd., Hadfields, Ltd., Sandycroft, Ltd., the Sturtevant Engineering Co., Ltd., Vickers, Ltd., to mention only a few, manufacture jaw crushing machinery. The Blake crusher, illustrated in Fig. 1, is a well-known type of jaw crusher. It consists of a rectangular frame, made of cast-iron or steel, provided with two sets of bearings on the sides to support the swing stock and eccentric shafts. Hanging from the swing stock shaft is the swing stock to the one side of which the swing jaw faces are fastened and having on the other side a groove in which is fitted a set of toggle bearings, and at the lowest edge of this face an eye to which is attached one end of the draw-back rod. Suspended from the eccentric shaft is the pitman, consisting of a rectangular casting made of cast iron or steel bored and bushed at its upper end to fit the eccentric shaft, and carrying on either side at its lower end a groove fitted with toggle bearings. At the non-crushing end of the frame there is an adjusting wedge whose position can be altered by two bolts passing through the frame. In front of this wedge is a second wedge-shaped block termed the adjusting toggle-block, which can only be moved in a horizontal direction by raising or lowering the adjusting wedge. The outer face of this adjusting toggle block is grooved and fitted with a set of toggle bearings.

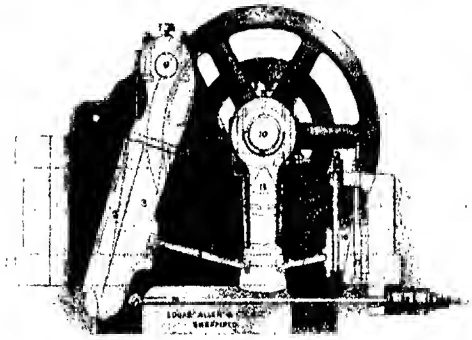

Fig. 1

Blake Crusher by Edgar Allen and Co., Ltd.

Two sets of toggles are used, one extending between the toggle bearings on the swing jaw and the front set on the pitman, and the second set stretching between the rear set on the pitman and the bearings in the adjusting block. Since the toggle bearings on the pitman are at a lower level than the bearings on the swing jaw and the adjusting block, when the pitman is raised the swing jaw moves towards the front end of the machine upon which is mounted the fixed jaw plates. The parts of the frame which are exposed to the abrasive action of the material between the jaws are protected by check plates. Formerly the main frame was always made of cast iron, but cast steel is now used in a number of machines, especially in the larger-sized ones. The replacement of cast iron by steel in the manufacture of crushing machinery has resulted in a considerable saving in weight, an important point in portable machines, and reduces the cost of transport. Machines made of steel, half the weight of a similar machine made of cast iron, would be three times as strong. When cast-steel frames are used, the best makers take great precautions to ensure that the sides are parallel to each other and at right-angles to the ends, thus

providing for a uniform distribution of stresses through the frame. The eye of the pitman is bushed with brass or babbit-metal, but the latter is to be preferred,

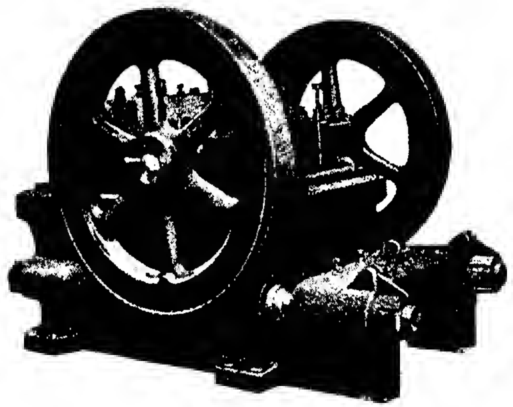

Fig. 2
Bigelow Crusher by Sandycroft, Ltd.

Sometimes, especially in the larger machines, the pitman is made in two portions, the cap and the stock, so that the pitman can be removed without the withdrawal of the eccentric shaft. The jaw faces may be made of chilled cast iron or manganese steel and every care should be taken to ensure that they are properly bedded on their respective seats. Those surfaces of the cast-iron frame, swing plate, and chilled cast-iron jaws which come into contact can be easily machined as can be the carbon-steel frames and swing plates, but manganese steel has to be ground to obtain true surfaces. Several types of manganese-steel jaws are manufactured. In one, the jaw plate is cored internally leaving a flat surface at the back for grinding, whilst another plate is cored at the back to form pockets which are usually filled with spelter to form the bedding surface. In the third type the jaw is cast solid and accurately ground on the back, whilst the fourth type consists of a manganese-steel shoe to which is fitted a cast-iron back, the joint between the steel and cast iron being formed of spelter, the cast iron only in this case being machined. The angle formed between the crushing surfaces is called the angle of nip, and the larger

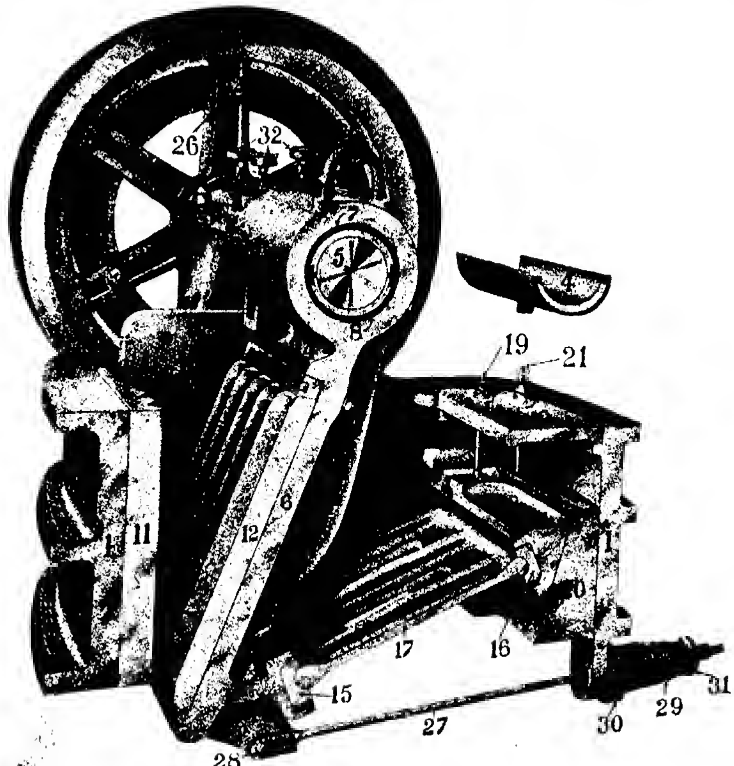

Fig. 3
Samson Crusher by Hadfields, Ltd.

since being softer than brass the scouring action of particles entering between the shaft and the bush is practically eliminated. A method of adjusting the wear on the pitman is shown in the illustration.

this angle the greater will be the opening at the top of the jaws. If it exceeds a certain amount, termed the critical value, the material will not be crushed, but will be forced out of the machine by the closing

of the jaws. The safe angle of nip about 32° is always [illegible] the critical angle to prevent the material from being [illegible] the jaws. A small size machine having a [illegible] g and 6 in. broad when working on hard limes[illegible] running at 250 revolutions per minute, can cr[illegible] from 3 to 5 tons per hour to pass through a 2½-in. ring. The largest size has

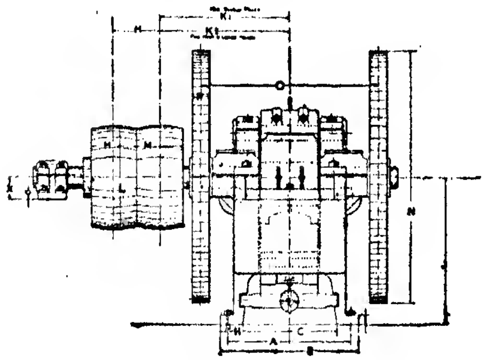

Fig. 4

Dodge Crusher by Frazer and Chalmers Engineering Works

a jaw 6 ft. long, the opening between the jaws at the top being 4 ft. Running at about 120 revolutions per minute, this size can crush 400 tons per hour to 8-in. cubes. In the larger machines the bearings and eccentric are water cooled, and the frames are built up of carbon-steel castings, the faces of which are accurately machined and then bolted together.

The Bigelow crusher, illustrated in Fig. 2, is a double toggle machine very similar to the Blake. Here, however, the toggle bushes at the bottom of the pitman are above the level of the toggle bushes on the swing plate and adjusting block. The crushing, therefore, is accomplished during the descent of the pitman, which is thus subject to compressive stress during the working period, and as the weight of the pitman is added to the driving force, the turning moment is not so variable as in the ordinary type. In the machine illustrated, the adjustable toggle block rests on a machined surface projecting from the back of the frame, and the opening of the jaws is adjusted by two strong steel side rods, each of which passes through a hole in the front end of the frame and a hole at the outer end of the toggle block. During the period of crushing, therefore, these rods relieve the frame from tensile stress. It will be observed that the back toggle plate is made of two portions riveted together. These rivets are designed to shear should any uncrushable material, such as a piece of iron, fall between the jaws, and thus save the machine from injury. Another form of crusher is the Samson or single toggle machine, a sectional view of which is shown in Fig. 3. As will be seen from this illustration the swing stock is again pivoted above the frame of the machine, but here the shaft supporting the swing stock is connected to the driving wheels and forms the eccentric for moving the swing stock. With such an arrangement a pitman is unnecessary, and as the motion of the swing stock varies from circular at the top to elliptical at the foot, the major axis of the ellipse being vertical, it is necessary for the driving pulley to rotate downwards towards the crushing opening so that the material may be carried down between the jaws. These are adjusted by moving the wedge-shaped block at the back of the machine.

Machines of this type are made in sizes varying from 10 in. by 6 in. to 20 in. by 10 in. opening, and at their normal running speed of 250 revolutions per minute can reduce from 3 to 5 tons in the smaller machines or 10 to 15 tons in the largest size of hard limestone per hour to pass through a 2½-in. screen. If such machines are used as secondary crushers or granulators crushing the same material to pass through a ¾-in. mesh, the output becomes 3 tons for the smallest machine to 7 tons for the largest machine.

In all the machines mentioned so far the swing stock is pivoted above the frame, but in the Dodge crusher, Fig. 4, the swing stock is pivoted at its lowest point. The swing stock shaft is carried by movable bearings which are fitted in recesses in the side plates, and are moved by means of adjusting screws so that the opening of the jaws can be varied and the wear compensated. The swing stock is of the bell crank lever type, and is specially strengthened and actuated at its outer end by an eccentric. The eccentric rod which communicates the motion from the eccentric to the swing stock terminates at its upper end in a cylindrical surface which fits into a cylindrical groove cut in the end of the swing stock piece and forms a joint permitting the jaws to move in the manner described above. The weight of this swing stock keeps the stock in contact with the end of the eccentric rod. Machines of this type are made having openings varying from 4 in. by 6 in. to 11 in. by 15 in., their capacities when running at 275 and 210 revolutions per minute respectively being for the

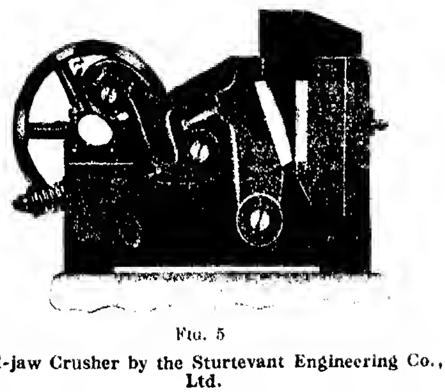

Fig. 5

Roll-jaw Crusher by the Sturtevant Engineering Co., Ltd.

smallest sizes about 1 ton per hour, and for the larger sizes 8 to 10 tons per hour when reducing to nut size.

Figure 5 shows a roll-jaw fine crusher, made by the Sturtevant Engineering Co., Ltd., which works on the Dodge principle. Here the pivot of the swing stock is again at the lower end, but is placed much

lower and behind the end of the jaw face so as to give considerable movement at the point of minimum opening of the jaws and a clear fall for the crushed material. The swing stock is driven, in contrast to the method adopted in the previous machine, through a toggle extending between one bearing on the back of the swing stock near the top end and a second mounted on a rocking lever. This rocking lever pivots at its lower end on a shaft carried on two adjustable bearings housed in suitable recesses in the sides of the machine, whilst the upper end is fitted with a roller resting on a cam mounted on the driving shaft. Smooth manganese steel jaws are fitted on this crusher, whilst the sides of the frame are made of steel plates and the ends, rocker arm and swing stock of cast steel. As the machine is intended for fine crushing the toggle plate is sometimes made of cast iron to prevent damage due to the admission of pieces of excessive size. Such machines are made in sizes varying from a 4 by 8 to a 7 by 24-inch opening. A machine of the first size is capable of crushing, when running at 350 revs. per minute, 10 cwt. of iron pyrites per hour when the jaws are set ¼-in. apart, and the latter machine can handle 3 tons per hour when the jaws have ½-inch opening to 6 tons per hour, when the opening is increased to 1 inch, the speed of running in each case being 150 revolutions per minute. The cam and roller device is introduced to give smooth action and easy running. Since the movement of the swing stock in the Blake type of crusher is greatest at the lower (outlet) end of the machine, there is little danger of packing, but this freedom of passage of material through the machine often results in an inequality of product. On the other hand the movement at the outlet of the jaws in both the Samson and Dodge types of crushers is small, and therefore a more uniform product is likely to be obtained, but this small movement does not permit of a ready discharge of the material, which is therefore liable to pack unless attention is paid to of crusher. In addition of this type have their own p. periphery of th operation as intermediate crushers b the an the large Blake or gyratory machines and the crushing rolls or ball mills.

Disc Crushers

Disc crushers embody an entirely different crushing principle which is extremely simple and at the same time very effective. Two types of machine are manufactured: the Symons horizontal disc crusher, for which Hadfields, Ltd., hold the patent rights for the British Empire, and the Symons vertical disc crusher, which is manufactured in this country by Sandycroft, Ltd. Fig. 6 represents a sectional view of the horizontal type. The main frame carries three coaxial bearings, of which the first two carry a hollow outer shaft rotated by a pulley mounted between the bearings. One end of this shaft is made in the form of a hollow hemisphere to the flange of which is bolted a spider or frame to which is fixed a concave disc with the concave side facing the shafting and having a hole in the centre through which the material is fed into the machine. Facing this disc is a second concave disc mounted on a hemispherical bearing resting in the cup of the hollow shaft. This hemispherical end is pressed on a second shaft which passes through the outer shaft and terminates in an eccentric carried by the third or eccentric bearing. To this eccentric is fixed a second pulley, which is usually driven at twice the speed of the driving pulley and in the opposite direction so as to increase the number of crushing nips. The eccentric is not attached to the second shaft and does not cause it to rotate, but simply gives it a gyratory motion. The two crushing discs rotate at the same speed and in the same direction.

The bearings are dust-proof, and forced lubrication is maintained by means of an oil pump driven from the eccentric pulley. The discs are enclosed in a hood made in two portions which are hinged on

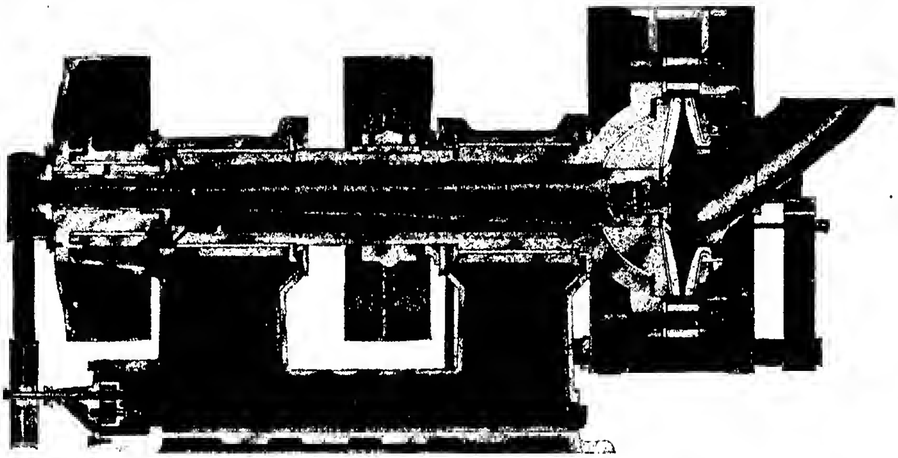

Fig. 6

Horizontal Disc Crusher by Hadfields, Ltd.

the rotary fine ert. main frame, thus enabling it to be eas...ance, we inspection or repair of the crusher. Lining the hood round the portion facing the opening between the discs is a series of segments forming a channel rectangular in cross section. The rods carrying the hood are also used to support the spout through which the material enters the space between the discs. The action of the machine is extremely simple, for on entering the space between the discs the material is thrown outwards and becomes wedged between the discs, in which position crushing is produced by the gyratory motion of the inner disc. This action is repeated until the pieces are sufficiently reduced to be thrown out by centrifugal force through the space between the outer edges of the discs which can be adjusted by means of bolts carried on the spider. The crushing discs are made of manganese steel and are found to undergo very slight but uniform wear, since there is no grinding action; the makers attribute this to a slight differential motion between the plates. This crusher is made in four sizes in which the diameters of the crushing discs vary from 48 to 18 inches. The largest size machine running at 100 revolutions per minute is capable of crushing 70 to 90 tons per hour to pass through a 2½-inch ring, whilst the smallest size can crush 6 to 8 tons per hour to pass through a ½-inch ring when running at 200 revolutions per minute. These machines are capable of crushing round silica pebbles when wet. The Symons vertical disc crusher illustrated in Fig. 7 is formed of a base upon which are mounted two hollow concentric cylindrical pedestals. The inner and longer pedestal is surrounded at its upper end by the sleeve of the lower table, which is supported on roller bearings resting on the top of the outer pedestal. The table is rotated through bevel gearing mounted on the counter-shaft of the machine and carries a number of spider bolts to which are attached the spider plate and upper spring plate, which in turn support the upper disc plate. This adjustable plate is conical in shape and carries the upper crushing face on its under surface. Inside the inner pedestal is a shaft which is rotated by a second bevel gear driven by the counter-shaft of the machine. The tail shaft of a circular convex rolling-wedge shaped like a mushroom fits into a hole drilled eccentrically in this shaft. The flat surface of the wedge rests upon the table and rotates with it. On the top of the wedge rests the upper disc plate made concave on the under surface to fit the wedge but flat on top to carry the lower disc. The rotation of the shaft carrying the stalk of the wedge causes the latter to move relatively to the table and thus produces an undulating motion in the lower disc and crushing face. The material enters the machine through a central hole in the upper disc plate and is thrown by centrifugal force into the tapering portion between the discs. Wedged in this position the material is crushed by the wave motion given to the lower disc. When the material has been crushed sufficiently it is discharged at the peripheries of the plates into the surrounding casing. The opening between the discs is adjusted in the following ingenious manner: the inner vertical surface of the upper spring plate and the outer vertical surface

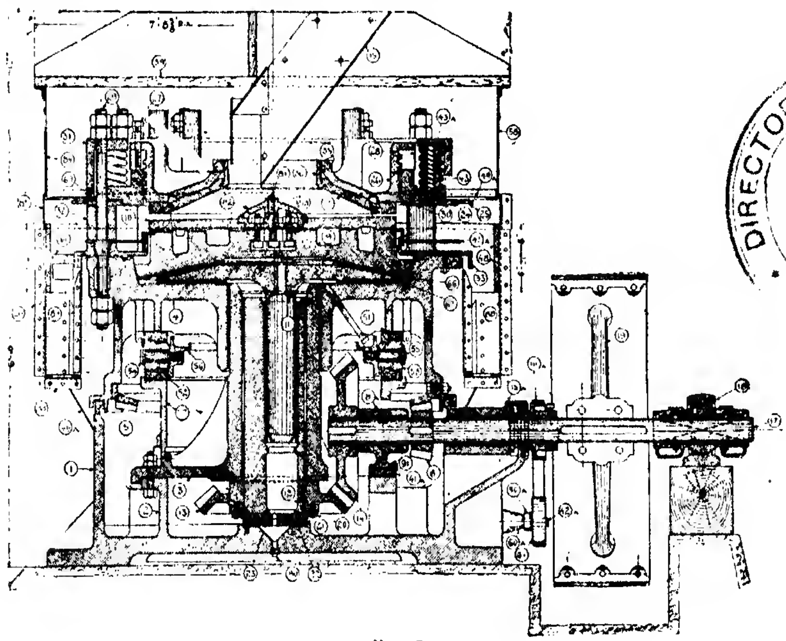

FIG. 7

Symons Vertical Disc Crusher by Sandycroft, Ltd.

of the upper disc plate are screwed to fit each other; the upper disc plate is rotated by means of one of the two turnbuckles fastened at one end to the bolts carrying the spider plate and at the other to lugs cast on the upper disc plate. After this adjustment the second turnbuckle is put in position and in addition the adjusting bolts are screwed up thus preventing any further relative motion between the plate and the spider. A 48-inch Symons vertical disc crusher is capable of reducing 100 to 120 tons of material from 5-in. to 1-in. cubes per hour, or 90 to 100 tons of 3 to 4-in. cubes to ½-in. cubes in the same time or 20 to 35 tons from 1½-in. to 2½-in. cubes to ¼-in. cubes in the same time. Springs are fitted between the spider plate and the upper spring plate which operate when any hard material is accidentally admitted to the machine.

Machines of the disc type are continuous in their action and therefore have a more uniform turning moment than the jaw type [illegible]. In addition the area of discharge at the [illegible] crushing surfaces more nearly equals the area of the opening at the feeding end of the machine, and therefore there is little danger of the packing of the machine.

Gyratory Crushers

Another type of crusher manufactured by firms such as Edgar Allen and Co., Ltd., Fraser and Chalmers Engineering Works, Hadfields, Ltd., and Vickers, Ltd., is the gyratory crusher, of which Fig. 8 is a sectional illustration. At the outset it should be stated that the crushing cone does not rotate as is commonly supposed. The erroneous idea that the crushing cone rotates may be due to two causes, namely, either the slight rotation of the cone when the machine is running light caused by friction between the rubbing surfaces of the driving mechanism, or the confusion of the action of this machine

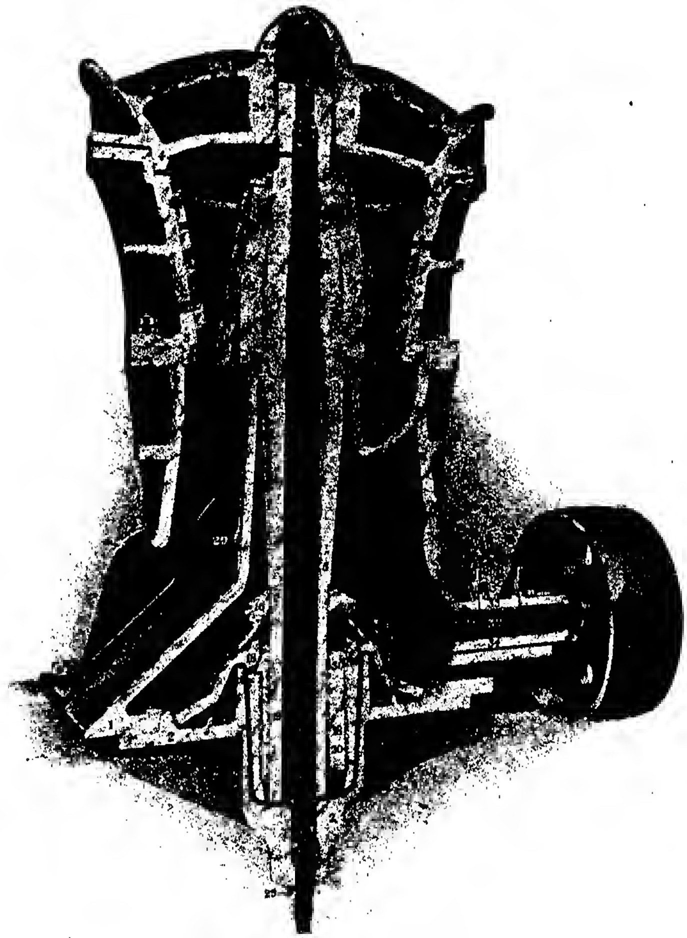

Fig. 8

Gyratory Crusher by Hadfields, Ltd.

with the rotary fine crusher, which, although very similar in appearance, works on an entirely different principle, as will be shown later. The machine has a cast-iron base shaped like a truncated cone, which converges upwards and is divided internally into two portions by an inclined plate having a tubular piece extending upwards concentric with the axis of the cone. The removal of the wall of the cone for a little way above the bottom of this inclined plane provides an outlet for the crushed material from the machine, whilst provision is made for a bearing at the bottom of this casting immediately opposite this outlet. Bolted to the upper flange of this casting is a second truncated cone converging downwards and having internal conical liners made of manganese steel, the surfaces of which may be either smooth or corrugated.

To the upper flange of this second cone is bolted a third, also converging downwards, and provided with two spider arms to support a spider cap concentric with the axis of the machine. This spider cap is fitted with a bush through which passes the central shaft supported in a footstep bearing carried by the bed plate of the machine. Surrounding this central shaft is the main shaft, at the upper end of which the cast steel centre is fixed. The lower end of the main shaft passes through an eccentric placed in a suitable housing in the bed-plate of the machine, and connected at its upper end to a bevel wheel driven by a second bevel wheel mounted on the shaft carried by the bearing at the bottom of the lower casing. A manganese steel mantle is securely fixed to the outer surface of the cast steel centre. The counter shaft rotates the eccentric, by means of the second bevel wheel and causes the lower end of the main shaft to describe a circle without rotating the shaft itself, thus giving the motion of a conical pendulum to the main shaft and mantle. The material to be crushed is fed into the top of the crusher, and falling into the wedge shaped annulus formed by the concaves and the mantle is crushed by the movement of the latter.

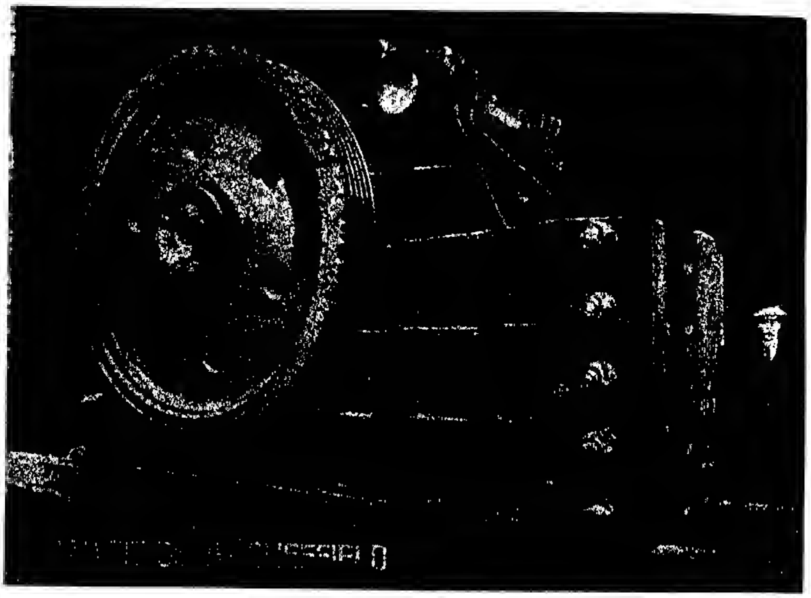

FIG. 9

Large-size Blake Crusher

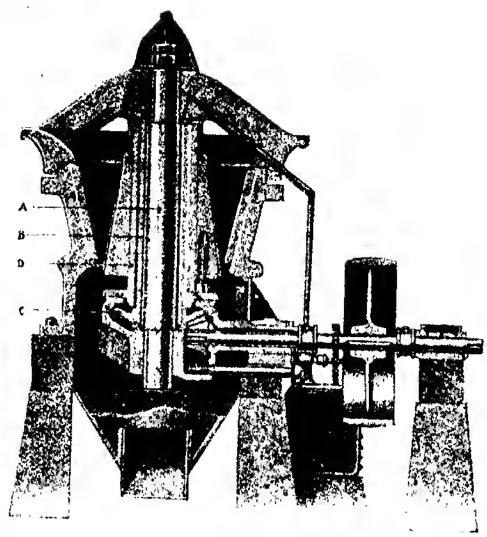

FIG. 10

Symons Gyratory Crusher by Frazer and Chalmers Engineering Works

On the release of the pressure the material drops further into the annulus, and is again crushed, the process being repeated until the particles are sufficiently small to pass through the opening between the bottom of the concaves and the bottom of the mantle. The material, falling through this opening, slides down the inclined plane, and is discharged from the machine.

The Symons gyratory crusher, made in this country by Fraser and Chalmers Engineering Works, and illustrated in sectional view by Fig. 10, is very similar to the gyratory crusher described above. In this machine, however, the centre shaft is carried in fixed bearings and is surrounded between the bearings by an eccentric sleeve, which is rotated by bevel gearing. Surrounding this eccentric sleeve is the head lining to which the mantle is fixed. In this case also the mantle does not revolve around the central shaft, but approaches to and recedes from the concaves by the rotation of the eccentric sleeve, the movement being equal throughout the length of the crushing head instead of gradually decreasing towards the top. The makers state that this machine requires less head room, gives greater stability and freedom from vibration and better distribution of the crushing stress, thus making for a reduction in weight with a corresponding lessening in cost. The gyratory crusher, being continuous in its action, produces a more uniform torque on the driving shaft. Like the disc machines, but not to the same extent, the outlet area from the crushing surfaces, on account of the increased diameter, approaches the inlet area, and thus tends to prevent packing of the machine. The inlet to the machine is in the form of an annulus, and thus prevents blocks of material from entering the crushing space, which could easily enter between the jaws of a Blake crusher having the same inlet area.

If the material is supplied in very large blocks it is necessary to install a Blake crusher for preliminary treatment before the material is allowed to enter the gyratory machine. The capacity of gyratory crushers also depends upon the nature of the material to be crushed and the size of the product desired, but machines have been constructed having capacities varying from 5 to 500 tons per hour. The horse-power required by the gyratory crusher is considerably less than that used in a Blake machine when both machines are reducing a similar quantity of the same material per hour to the same degree of fineness. The size of product obtained from these machines usually varies from $4\frac{1}{2}$ to $1\frac{1}{2}$ ins. in diameter.

PULP AND PAPER INDUSTRY IN CANADA

The Wayagamack Pulp and Paper Co., Three Rivers, Quebec, has received a loan of £400,000, under the Trade Facilities Act from the British Government and is expending the money in the purchase of machinery in Great Britain for the purpose of expanding the present plaut.

THE CHEMICAL INDUSTRY DINNER

The joint Dinner of the Society of Chemical Industry and the Chemical Industry Club was held at the Edward VII Rooms, Hotel Victoria, London, on November 14. Mr. W. J. U. Woolcock, C.B.E., President of the Society of Chemical Industry, was in the chair, and over 300 ladies and gentlemen were present.

It is impossible to give the names of all; many members of the Council of the Society and of the committee of the Club were present, and the guests and persons occupying official positions included Sir Richard T. Glazebrook, K.C.B., F.R.S.; Mr. H. E. Coley, Chairman of the Club; Sir Arthur Duckham; Sir Robert Robertson; Sir Frederick Nathan; Mr. Percy Ashley, of the Board of Trade; Mr. D. Milne Watson; Mr. G. Rudd Thompson; Mr. W. S. Hale, the Master of the Tallow Chandlers' Company; Prof. C. G. Henderson, the President of the Institute of Chemistry, and Mr. A. Chaston Chapman, the President of the Chemical Industry Club.

"Chemical Industry and the Profession of Chemistry" was proposed by Sir R. T. GLAZEBROOK, who, after referring to the book, "Chemistry in the XXth Century, prepared for the Wembley Exhibition, said there was no doubt whatever that there had been a complete change in the life of the world as the result of the development of scientific methods and their practical applications. Of the sciences which had led to that change, chemistry was not the least. The productiveness of human labour at present was dependent on the advance of scientific knowledge, and in this chemistry was playing no small part. How large a part chemistry was playing had been shown in an admirable manner at the Wembley Exhibition. It could not be denied that the progress of chemistry had been of the greatest importance to the world as one of the means by which human labour was made productive. He himself was a physicist and confessed to being taken aback when he first heard on the committee of the Royal Society, which dealt with the pure science exhibit, that such distinguished men as Rutherford, the Braggs and J. J. Thomson were regarded as chemists. He had lunched with Rutherford that day and asked him if he liked being called a chemist, and Rutherford's reply was that if the chemists liked to give that name to one who knew no chemistry he did not mind. The Royal Society Committee was enormously assisted by Mr. Woolcock in its work, although it was possible that at first he rather felt a little doubtful as to how far the Royal Society Committee was in earnest. The distinction between chemistry and physics had vanished, and the complete chemist must be a physicist. As a matter of fact, the chemist must be much more. He must be a person trained to reason, doubting all things, ready at all times to discuss, he must have a wide vision and a fertile imagination guided and controlled by his reason and by his results of experience. He must be apt at experiments and ready to iuterpret their meaning. Such men were needed in industry, and if the Society of Chemical Industry and

the chemical industry and the work of professional chemists were to flourish, such men must be forthcoming, and they would be forthcoming so long as the ideas set forth in the Exhibition at Wembley inspired their work.

MR. D. MILNE WATSON said it was a great privilege to him to reply to the toast so eloquently proposed by Sir Richard Glazebrook. He was very glad to be present as an industrialist and as a guest of the Society of Chemical Industry of which he hoped soon to be a member. The conjunction of science and industry exemplified in that dinner showed the progress that had been made in the last few years in bringing scientific chemists and industrialists together. He believed the work of the Society of Chemical Industry was of great importance. He had been immensely impressed with the scientific exhibition at Wembley, and speaking as a manufacturer he felt that without that scientific exhibition the individual exhibits at Wembley would have lost a great deal of their meaning. There had been a very great extension of chemical plants during the War, but in the impoverished state of the world now it would take many years to get the work of all these plants absorbed. The hope of the future was that there should be closer working between science and industry; indeed he believed that was the only hope, if the trade and commerce of this country were to regain their former position.

PROF. G. G. HENDERSON also replying to the toast said it was significant that the "profession of chemistry" should have found a place in the toast list. Not many years ago it would have been ludicrous to have talked of the profession of chemistry. There were at that time many distinguished chemists but no profession as such. The position now was entirely different, and this great change could be attributed to at least three factors, two of which were more recent, and one more remote. One of the more recent factors was the Great War. The second factor was that wonderful display in the chemical exhibit at Wembley, which they owed to one man, their Chairman that evening. The third and more remote factor which had contributed so greatly to the improvement of the chemical profession was the quiet and continuous work of the Institute of Chemistry carried on for the last half-century. But they were not satisfied with the position which the profession occupied at the present moment, and they would not be satisfied until chemistry ranked at least equal to any other profession in the country. That stage had not yet been reached, and in attempting to do so, two steps were obvious. The first was that they must speak with one voice as a united profession, and that could only be realised by having some central organisation with central headquarters. The second step was equally obvious; it was essential to make the general public realise the part played by chemists in the common life.

MR. A. CHASTON CHAPMAN, F.R.S., who proposed "The Society of Chemical Industry," said that he welcomed the opportunity of offering to the great Society, which the Club looked upon as its parent, an expression of its warm and filial regard and to express the hope that the close connexion which had always existed between them would for ever continue. The Society was one of the great trinity of Chemical Associations which represented in such an admirable manner British chemistry. There was now a greater degree of co-operation in the whole of the industry and profession than ever before, and the Chemical Industry Club was anxious to help in any way it could to develop this co-operation.

MR. W. J. U. WOOLCOCK said the Society of Chemical Industry was flourishing; its duty was to publish scientific papers, and there were certain things which it could give to its members in return for their membership, but generally speaking the members of the Society knew that they were supporting something which stood for an ideal and which commercially could not be reckoned as an asset. They knew that the Society stood midway between science and industry. They knew that in this country there were millions of people who required to be educated in the value of science to the nation. They knew that they were responsible for proving to every industrialist that he could be more efficient, and that in the fight for markets and the maintenance of British trade there was no industry that could not be improved by a better appreciation of science and by a bigger influx into the works of the chemist. He was delighted that Professor Henderson had got so near and yet did not mention Chemistry House by name. He knew that that great project had Professor Henderson's fullest sympathy, and he could speak with certainty to the same effect for the President of the Chemical Society, and for Mr. Chaston Chapman. They were not going to hurry the matter, but he assured them that if there was less talk about Chemistry House at the moment there was more thought and a greater attempt to crystallise ideas at the present moment than had ever existed before. The past year had shown in a remarkable way the degree of co-operation among learned bodies and, better still, among individual sciences. There was a greater degree of co-operation than had ever existed before. Never again could it be asserted that there was any difficulty whatever in getting scientists to work together. It was untrue. It was the easiest possible thing in the world.

MR. C. S. GARLAND, proposing "The Chemical Industry Club," said it was with the greatest pleasure that he coupled with the toast the name of Mr. Coley, because it was to Mr. Coley that the genesis of the Club belonged. He had worked extremely hard to bring the Club into being, and a few years ago the idea that chemists could fraternise together was appalling. However, the Chemical Industry Club had shown what chemists could do in this matter.

MR. H. E. COLEY, replying to the toast, referred to the progress of the Club, and claimed that it had justified its existence. His remarks about the success of the Club were much appreciated.

The final toast, that of "The Guests," was proposed by DR. W. CULLEN, in an amusing speech.

MR. PERCY ASHLEY, in reply, said nothing was more important to the country than that its industries should be so organised that they could speak authoritatively to the Government and to Government Departments, and give a clear indication of

what industry thinks to be its requirements and as to the manner in which the State might help. The Government and its Departments desired to get at the truth; they wanted to help industry, but industry must indicate clearly and unanimously the lines upon which help could be given.

OPENING OF THE RAMSAY LABORATORY OF CHEMICAL ENGINEERING

On November 12, H.R.H. Prince Arthur of Connaught opened the Ramsay Laboratory of Chemical Engineering at University College, London. Sir R. Robertson, who presided, said in this country technical chemists were lacking who could transfer a laboratory operation to large-scale work. After discussing the training, he urged chemical manufacturers to afford facilities similar to those provided in the United States, where it was a practice to take students to works.

Prince Arthur of Connaught, in declaring the laboratory open, said the ceremony was the final act in the provision of a worthy memorial to that great man of science, Sir William Ramsay, who, from 1887 to 1913, held the Chair of General and Inorganic Chemistry at that college. After his death in 1916 a large circle of friends and colleagues not only in this country but in all parts of the world, decided that a fitting memorial should be raised to his memory. The appeal was of an international character, and met with a ready response from all parts of the British Empire and the world. The memorial had taken two main forms: (1) The foundation of Ramsay Memorial Fellowships in Chemical Science, and (2) the foundation of a Ramsay Laboratory of Chemical Engineering. The success of the first half of the scheme was shown by the fact that the Fellowship Trusts were now administering 16 scholarships held by carefully-selected Fellows from various countries. Professor E. C. Williams was appointed a year ago to the Ramsay Chair of Chemical Engineering, and it was under his guidance that the laboratories had been reconstructed and equipped. He was gratified to learn that, apart from the support given to the movement by the Ramsay Memorial Fund, which handed over a sum of £26,979, the Laboratory of Chemical Engineering had enlisted the ready and generous support of many of the great firms of this country which were connected with the chemical industry. A sum of approximately £1390 a year for five years had been provided in this way. Even now further financial support was needed if the department was to be enabled to rise to its full possibilities.

Mr. W. J. U. Woolcock, C.B.E., president of the Society of Chemical Industry, said the opening of the Ramsay Laboratory marked a step forward. The hybrid nature of the chemical engineer had delayed immediate recognition, but the new and pioneer laboratory was likely to produce men who would in time be recognised as worthy to rank with members of both the chemical and engineering professions. He was delighted to find how Prof. Williams laid stress on the ability to plan large-scale commercial operations, and the laboratory would enable training to be given not only in that direction but in the designing and operation of chemical plant. A number of individuals and firms engaged in chemical industry had shown in a practical manner their interest in the work, and he hoped this interest would grow. For the complete training of the students some works experience was required, but it was unusual for manufacturers to admit students to their works. It was done in the newer countries, and the possibility of doing it should be kept in mind.

FORTHCOMING EVENTS

Nov. 24. Royal Society of Arts, John Street, Adelphi, London, W.C. 2, at 8 p.m. "Modern Colour Problems," by L. C. Martin.

Nov. 25. Society of Dyers and Colourists, *Leeds Junior Branch*, Visit to Messrs. Brotherton and Co. Stourton Tar Works, commencing at 2.30 p.m.

Nov. 26. Royal Microscopical Society, 20, Hanover Square, London, W. 1, at 7.30 p.m., Joint Meeting with the Institution of Structural Engineers. (1) "The Elementary Principles of Microscopical Illumination: Self-Luminous Objects," by J. E. Barnard. (2) "Application of Microscopy to Cement Research," by H. J. Deane.

Nov. 26. Institute of the Rubber Industry, *Manchester and District Section*, the Textile Institute, 16, St. Mary's Parsonage, Manchester, at 7.30 p.m. "Treatment of Rubber previous to Vulcanisation," by Dr. S. S. Pickles.

Nov. 26. Society of Chemical Industry, *Glasgow Section*, 39, Elmbank Crescent, Glasgow, at 7 p.m. "The Future Prospect of a Clean Atmosphere," by ex-Bailie W. Brownhill Smith.

Nov. 26. Institute of Chemistry, *Leeds Section*, The University, Leeds, Annual Meeting. Address by Prof. Cobb.

Nov. 26. Institute of Chemistry, *Birmingham and Midland Section*, Annual General Meeting and Address by Prof. G. T. Morgan, F.R.S.

Nov. 27. Society of Dyers and Colourists, *Midlands Section*, Joint Meeting to be held at Nottingham with the Society of Chemical Industry. "Acetate Silk," by G. H. Ellis.

Nov. 27. Institute of Brewing, *Yorkshire and North Eastern Section*, Queen's Hotel, Leeds. "1924 Barleys," by C. E. Sutcliffe and H. M. Chubb.

Nov. 28. University of London, King's College, Strand, W.C. 2, at 5.30 p.m. "Scientific Method," by Prof. E. W. MacBride.

Nov. 28. Institution of Mechanical Engineers, Storey's Gate, London, S.W. 1, at 7 p.m. "Centrifugal and Rotary Pumps," by G. L. Ponsford.

Nov. 28. Institution of Mechanical Engineers, *Yorkshire Section*, Visit to Messrs. Steel, Peech and Tozer, Sheffield, followed by paper on "The Effect of Repetition Stresses on Steels," by Prof. F. C. Lea.

Nov. 29. Society of Dyers and Colourists, *West Riding Section*. "The Dyeing Properties of some Azo Derivatives of Tetra Hydro Naphthalene," by Dr. F. M. Rowe and V. Tarbott.

SOCIETY OF CHEMICAL INDUSTRY

SUSPENSION OF ENTRANCE FEE

As an inducement to Chemists to become members, the Council has resolved that no entrance fee shall be paid by members joining the Society in 1925.

A form of application for membership was inserted at the end of this Section in the issue of the Journal for October 17, and it is hoped that it may be used to introduce a new member for next year.

BACK NUMBERS OF JOURNAL

The General Secretary will be glad to hear from Members or Subscribers who have copies of the *Journal* for January 5, 1923, or January 4, 1924, that they are willing to dispose of to the Society.

MEMBERS ELECTED, November 14, 1924

Antonoff, Dr. George, 6, Featherstone Buildings, High Holborn, London, W.C. 1. Research Chemist.

Baldwin, John W., 211, New Buckingham Street, Holderness Road, Hull. Engineer.

Barclay, T., Charford Mills, Saltley, Birmingham. Director.

Buckley, Robert, 179, Bedford Road, Rock Ferry, Birkenhead, Cheshire. Analytical Chemist.

Coxon, Thomas, Mill Lane, Billingham, Stockton-on-Tees. Chemist.

De Blois, William H., 570, Claremont Avenue, Westmount, Quebec, Canada. Chemical Engineer.

Denchar, John L., The Castner Kellner Alkali Co., Ltd., 257, Royal Liver Buildings, Liverpool. Director.

Edwards, Percival R., Rodway View, Staple Hill, Bristol. Chemist.

Hampson, Cyril C., c/o C. P. A., Ltd., Low Mill Print Works, Whittle-le-Woods, Chorley, Lancs. Works Chemist.

Hazeley, Edward, 7, George Eliot Road, Foleshill Road, Coventry. Chemist.

Hewer, Miss Dorothy G., 18, York Terrace, London, N.W. 1. Analytical Chemist.

Holliday, Major Lionel B., c/o L. B. Holliday and Co., Ltd., Deighton, Huddersfield. Aniline Dye Manufacturer.

Jack, William, 13, Willowbank Crescent, Glasgow, C. 3. Chemist.

Lorimer, James D., 117, Queen Street, Montreal, P.Q., Canada. Broker.

Lant, James G., c/o Anglo S. American Meat Co., San Martin 235, Buenos Aires, Argentine. Analyst.

McLaren, William, The Laboratory, 20, Laverockbank Road, Edinburgh. Fuel Technologist.

Metzis, Josef, A. G. "Galicia," Drohobycz, Poland. Manager.

Peak, Alfred E., "Greylands," Alderley Edge, Cheshire, Director.

Ridsdale, Noel D., 3, Wilson Street, Middlesbrough. Analytical Chemist.

Roswarne, Joel A. H. T., c/o "Bovril," Ltd., 148-166, Old Street, London, E.C. 1. Chemist.

Russell, John, 2, The View, Roundhay, Leeds. General Secretary, Brotherton and Co., Ltd.

Smith, Leonard E., 6, Greenway Road, Redland, Bristol. Chemist.

Southall, Reginald B., c/o The National Oil Refineries, Ltd., Llandarcy, Glam., S. Wales. Works Chemist.

Speight, Jacob, Moor House, Rishton, Lancs. Managing Director.

Starey, Arthur Wm., The Glaxo Manufacturing Co., Ltd., Port Fairy, Victoria, Australia. Chemist.

Stern, Harold J., 17, Croxteth Grove, Sefton Park, Liverpool. Chemist.

Wallis, Kenneth, 56, Harlaxton Road, Grantham, Lincs. Works Chemist.

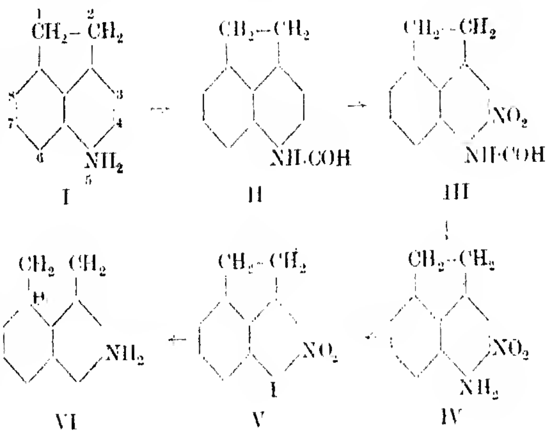
Wilson, Harold, 9, Egerton Avenue, Urmston, Manchester. Assistant Chemist.

BIRMINGHAM SECTION

The first meeting of the session was held on November 11, at the University of Birmingham, Prof. G. T. Morgan, F.R.S., this year's chairman of the Section, presiding. Four papers on researches from the chemical department of the University were presented :—

1.—"Studies in the Acenaphthene Series. Part I. 4-Aminoacenaphthene," by Prof. G. T. Morgan and H. M. Stanley. Hitherto only one of the four theoretically possible aminoacenaphthenes has been described, namely, 5-aminoacenaphthene (I) discovered by Quincke (*Ber.*, 1888, **21**, 1455).

4-Aminoacenaphthene (VI) has now been obtained by the following series of operations :—



The acyl derivatives of 5-aminoacenaphthene nitrate in position 4, but the nitroformyl compound being the most readily hydrolysed is employed in the foregoing synthesis. The nitrobenzoyl-5-aminoacenaphthene on reduction gives an anhydro-base, acenaphthene-4N : 5-benzenyldiamine (VIII). 5-Iodoacenaphthene on nitration furnishes two isomeric nitro-compounds, A (m.p. 180°) and B (m.p. 151–153°). The less fusible isomeride is 5-iodo-6-nitroacenaphthene since on reduction it yields 5-aminoacenaphthene. The more fusible isomeride is still under examination. The properties of the two aminoacenaphthenes were contrasted in a table.

2. "Researches on Residual Affinity and Co-ordination. Part XXIII. Interactions of Trimethylstibine and Platinic, Platinous and Palladous Chlorides," by Prof. G. T. Morgan and Victor E. Yarsley. By the interaction of trimethylstibine and chloroplatinic acid in alcoholic solution a portion of the antimony compound is oxidised to trimethylstibine dichloride and two co-ordination derivatives of bivalent platinum are obtained: bistrimethylstibinedichloroplatinum, $[2SbMe_3, PtCl_2]$, a yellow substance crystallising from organic solvents: tetrakistrimethylstibineplatinous platinochloride $[4SbMe_3, Pt.]PtCl_4$, an orange compound insoluble in organic media and converted into the preceding monomeric derivative at 60° or on long exposure to light at the ordinary temperature. Excess of trimethyl-

stibine converts the foregoing compound slowly into tetrakistrimethylstibineplatinous chloride, $[4SbMe_3, Pt]PtCl_2$, which is soluble in water, giving with aqueous potassium platinochloride a precipitate of the orange tetrakistrimethylstibineplatinous platinochloride, thus confirming the constitution of the latter as an analogue of the green salt of Magnus. The dichloride reacts with chloroplatinic acid and palladous chloride to furnish respectively tetrakistrimethylstibineplatinous platinichloride and palladochloride, $[4SbMe_3, Pt]PtCl_6$ and $[4SbMe_3, Pt]PdCl_4$. Bistrimethylstibinedichloropalladium,$[2SbMe_3, PdCl_2]$, is obtained from palladous chloride and trimethylstibine and when the latter reagent is in excess tetrakistrimethylstibinepalladous chloride, $[4SbMe_3, Pd]Cl_2$ is produced.

3. "Observations on the Higher Fatty Acids," by G. T. Morgan and Arthur R. Bowen.

(i) *The higher saturated fatty acids of Cacao Butter.*—The object was to investigate the acids of cacao butter as a source of eicosanic acid. According to Traub and Graf, cacao butter contains the saturated fatty acids arachidic, stearic, palmitic and lauric, but not theobromic acid, $C_{64}H_{128}O_2$, which had previously been reported by Kingzett. Hehner and Mitchell obtained pure stearic acid by repeated recrystallisation of cacao butter acids from alcohol. Ehrenstein and Stuewer (*J. pr. Chem.*, 1923 (ii), **105**, 199) have recently pointed out that arachidic acid from arachis oil is in all probability an *iso*docosanic acid, whilst the acid in rambutan tallow (from the seeds of *Nephelium lappaceum L.*) is the normal eicosanic acid. For comparison, pure *n*-eicosanic acid was prepared by potash fusion of erucic acid (Fitz, *Ber.*, 1871, **4**, 444) and a series of mixed melts with pure stearic acid worked out. The fatty acid from rambutan tallow (Ceylon) was also prepared and its identity with *n*-eicosanic acid confirmed. Recrystallisation of the saturated fatty acids of cacao butter from alcohol at 25° to 0·3 per cent. of the original weight resulted in the isolation of pure stearic acid. Heintz's method for the separation of higher fatty acids through the fractional precipitation of their magnesium salts was practised on the saturated acids of cacao butter until these were reduced to 1·8 per cent. of the original weight. This final residue was pure stearic acid.

(ii)—*The Existence of Bimolecular Complexes of the Fatty Acids.*—The curve obtained by plotting the melting points of *n*-eicosanic acid : stearic acid mixtures indicates evidence of compound formation of the composition 1 mol. $C_{20}H_{40}O_2$: 1 mol. $C_{18}H_{36}O_2$. The corresponding stearic acid : palmitic acid curve has been worked out with great accuracy by de Visser (*Rec. Trav. Chim.*, 1898, **17**, 182), who deduced from his results that "mixed crystals" were formed in the vicinity of the 50 per cent. mixture. However, there appears no foundation for this conclusion and the curve clearly shows evidence of compound formation. Möller and Shearer (*Chem. Soc. Trans.*, 1923, **123**, 3156) have shown that the higher fatty acids themselves are bimolecular, which result is confirmed by the work of Garner and Randall (*Chem. Soc. Trans.*, 1924, **125**, 881).

GLASGOW SECTION

The meeting on November 14 was held jointly with the Glasgow Section of the Institute of Chemistry, the Ardeer Chemical Club, and the Glasgow University Alchemists' Club, at Ardrossan. Mr. Wm. Rintoul presided and on behalf of the Ardeer Chemical Club, welcomed the visitors from Glasgow. The chairman, in introducing the lecturer, said the meeting was unique; it was the first occasion on which a paper was to be read at a joint meeting of the Societies held at Ardrossan, and it was an experiment which he hoped would be repeated. Mr. J. G. Roberts—of Messrs. Shanks, Barrhead—then delivered a paper, entitled "Chemical Pottery."

The ideal stoneware clay is one which, tempered with water, can be kneaded to such a plasticity as will give the greatest ease in working and the greatest uniformity in structure; a clay which will not shrink unduly on drying and firing, and that will burn to a dense semi-vitreous body at a moderate temperature, without losing its shape. Pots made of such material are liable to break when subjected to changes in temperature. Fireclays can be used to make vessels which will withstand sudden change of temperature, but these, on firing, remain porous, thus rendering necessary the use of a glaze if the finished article is used for the storage of liquids. Common salt is used to glaze stoneware jars, drain pipes and vessels for purely chemical purposes, while powdered galena gives the common yellow glazed joint. If pin-holes and unglazed patches be present, and the vessels be used for storing liquids and acid, iron compounds are dissolved resulting in the contamination of the stored liquid. Vessels, especially those of large size, whether made from clay bodies, or fused silica, are liable to break when under strain.

The methods adopted in manufacture vary according to the size and shape required. Those of small size and of circular form can be produced by the potter's wheel: those of large size are more easily made by pressing or building-up with plastic clay: while the production of "slip"—a mobile suspension of clay in water produced by deflocculating the clay with alkali or silicate of soda—and the subsequent casting in plaster of paris moulds, renders the production of vessels of uniform shape and thickness possible. The size of vessels made by casting is limited by the weight of slip (100 gall. of slip weighs almost one ton) used, the difficulty of getting the clay to stand up in the mould after removing the excess of slip, and the cost of moulds. A straight-sided vessel, such as a picric pot, has been cast up to a capacity of eighty gallons.

The greatest difficulty in the commercial production of chemical pottery lies in the varieties of shape and the comparatively small number of any one type of article required. Few articles, however, cannot be produced provided the initial difficulties in technique are overcome.

Porcelain may be regarded as the greatest triumph in the art of pottery. It is a composite body made up of quartz, china clay and felspar, and is produced usually from the mineral "pegmatite," a quartz and felspar rock which is comparatively free from iron

compounds. Ball clay is sometimes added when large articles are made, to give increased plasticity and strength to the unfired body. Manufacture comprises mixing, sieving, electro-magnetic separation of iron, filtration, wedging or casting, and firing.

The chemical composition of a particular porcelain may easily be found, but the manufacture of such an article is difficult owing to the obscure chemical and physical reactions. The chemical reactions are not allowed to go to completion, but are arrested at a particular stage, and, unlike many other processes, the difficulties are to be found in the unknown chemistry of "incomplete reactions." The physical condition of the ingredients are no less important than the chemical composition and variation of these conditions leads to disaster. Thus, quartz, for example, changes its crystalline form when heated and can exist in a metastable form in three distinct forms as quartz, cristobalite and tridymite, while each variety has two modifications—the alpha and beta forms. All these transformations are accompanied by expansion and take place below the melting point. Clay, again, breaks up below its melting point and when calcined to about 1000° C. forms a new-unidentified crystalline substance. At a higher temperature the so-called sillimanite is formed. No good heat resisting porcelain contains unchanged quartz, but always contains the needle shaped crystals supposed to be sillimanite, $Al_2O_3.SiO_2$.

Malinovszky produced these crystals upon the large scale, and the process, as developed by W. Smith, is known as the carbonised clay process of heating raw clay with coal. The carbonised clay has a high conductivity for heat and possesses the important property of hardness. It also results in the production of the afore-mentioned crystals, and in the separation of iron compounds. Brown and Greig have recently reported that the composition of the crystals is $3Al_2O_3.2SiO_2$ so that they are not sillimanite; they suggest the name "Mullite" as the crystals were identified in some natural rocks from Mull. Should the technical difficulties of manufacture be overcome the production of an excellent neutral refractory for temperatures up to 1800° C. is assured. Porcelain is thus regarded as a heterogeneous substance, composed of interlacing crystals embedded in a glassy matrix, and the lower the proportion of basic oxides, the more refractory does the body become.

The properties of special bodies such as fused silica, alumina, zirconia and artificial spinels were also commented upon.

In replying to the discussion, Mr. Roberts said that many of the troubles in the manufacture of pottery were due to the colloidal nature of the raw materials, together with the fact that equilibrium conditions were never obtained during the process. When sodium chloride was used, the glaze was a solid solution. He agreed that the recent work of Bingham and Green on plasticity was very valuable but the plastometer had not yet been perfected which could replace "the potter's thumb." The process was still "an art," but he looked forward with eagerness to the day when accurate determinations of plasticity would be possible.

The lecturer was accorded a hearty vote of thanks, and the thanks of the visitors were conveyed to the Ardeer Chemical Club for their hospitality by Prof. Wilson, on behalf of the Glasgow Sections of the Society, and Institute of Chemistry, and by Mr. Kerr, Hon. Secretary of the University Alchemists' Club.

MONTREAL SECTION

On the occasion of the visit of Dr. E. F. Armstrong, F.R.S., to Montreal, on October 14, he was entertained at an informal dinner at the Engineers' Club. The evening was spent pleasantly in discussing the affairs of the Society, both in England and Canada. It was brought out during the evening that a chemist coming from England to Canada must be prepared to finance himself for some considerable time until he can work himself from a lowly position into a remunerative one, just as graduates of Canadian Universities are obliged to do. Among those present were:—Messrs. J. B. Bell (chairman of section), C. F. Bardorf, J. R. Donald, N. N. Evans, C. R. Hazen, F. W. Horner, R. Job, C. G. Kertland, P. Le Cointe, M. C. C. McFee, H. W. Matheson, Dr. R. F. Ruttan, C. H. Wardleworth, and W. B. Woodland.

On October 20, the Bursary Committee, composed of Mr. J. R. Donald, Dr. Ruttan, and Prof. P. Lecointe, made a report at the opening meeting, submitting rules and regulations governing the bursary. This bursary is for the sum of fifty dollars, which is subscribed by the members of the Montreal Section, and is no charge on the funds of the parent Society. The bursary is awarded for the best paper on pure chemistry or chemical engineering written up from the practical experience of undergraduates in chemical works of various kinds during the summer vacation between their third and fourth years at college.

At the meeting which was held subsequently, Mr. J. A. Dresser pleaded for the development of industrial chemistry in Canada. The reason for the unfavourable trade balance in the mineral industry was that Canada was selling her raw products and buying back the manufactured article. A remedy for this adverse position would be manufacture on a larger scale, particularly in the chemical industry. The world looked to the chemist: every unit constituting modern civilisation was the work of the chemist; and the chemist held the world at his mercy.

In the ensuing discussion, Mr. J. R. Donald said metallurgy was of special significance to Montreal, which was in a mineral district. Major G. C. Dunanney said he believed Canada was on the eve of a great mining expansion, incident to the profound impression made upon the British intellect of the potentialities in this field revealed by the Canadian pavilion at Wembley: but it must remain with the technicians to blaze the trail. Mr. H. W. Matheson spoke briefly of the mining industry and its effect on the trade balance, and the possibilities of factories in Canada for making pigments. Sir Stopford Brunton emphasised the urgency of developing non-metallic industry. This industry was perhaps less spectacular

than gold mining, yet he believed it more essential as a national trade stabiliser. He concluded with a strong plea for the utilisation of Canadian water power by Canada, which he warned was in a fair way towards monopoly by the great corporations of the U.S.A. Mr. C. S. Bardorf said that raw kieselguhr was worth 5 cents a pound, but when worked up as a cosmetic it sold at 10 cents an ounce. Mr. A. Neighorn deplored the exportation of raw products instead of utilising them to build up industries. The chemists were not being utilised.

NOTTINGHAM SECTION

The third meeting of the session was held on November 5, Mr. G. J. Ward, chairman of the section, presiding.

Mr. C. E. Pickard, A.I.C., read a paper on "Observations on the Laboratory Testing of Enzyme Bates." Mr. Pickard outlined the various methods adopted for evaluating enzyme bates, and pointed out that the results obtained depend largely on the conditions of the tests, and only when comparative tests are made under absolutely identical conditions can the results furnish information of value.

The addition of ammonium chloride, ammonium sulphate or common salt to the proteolytic enzymes renders the enzyme about three times as active as when tested in the absence of these salts. The curve of activation by ammonium chloride is of the same type as the ionic dissociation curve of this salt, and beyond a certain point further increase in the ammonium chloride added produces no corresponding increase of activation of the enzyme. In practice the use of large quantities of ammonium chloride produces a too-rapid falling of the skins and the enzyme action is thereby inhibited.

Certain salts of the alkaline earths besides acting in some instances as "buffers," produce sudden changes of enzyme activity by converting inactive zymogens into active enzymes. This activating action of, say, the calcium ions varies with the origin of the pancreatin tested; different bates may possess different quantities of inactive zymogens. Any method used for the testing of bates must be preceded by (*a*) a complete qualitative analysis for bodies of physiological interest; (*b*) complete qualitative analysis for organic and inorganic substances; and (*c*) careful consideration of the influences of the results on subsequent work. No single method can be postulated as the best. Concentrations used in laboratory tests must be analogous to those used in bating. The bate solution should seldom exceed 1 per cent. and should act on at least two hundred times its weight of substrate. The relative quantity of substrate is small and lies under the grain layer, being reached only with difficulty by the enzyme. The bating activities follow the linear law and the use of slightly increased quantities of enzyme (without delimer) increases the velocity of reaction. Further increase in the quantity of enzyme results in the attack of other constituents of the skin substances such as collagen. The opinion that laboratory tests should be carried out on excess of substrate assumes that the whole skin and not merely the elastin and albuminous contents act as substrate. Laboratory methods cannot indicate the refinements of bating such as soft, silky grain, and "feel" which characterise a correctly bated skin. It is concluded that whilst the various laboratory methods provide working information of value, such as the control and standardisation of the proteolytic activities of bating materials, their results as criteria of relative bating efficiencies, must be accepted with considerable reserve.

In the discussion Mr. Law stated that he was of the opinion that of the tests put forward the gelatin substrate method was the nearest approximation to that operating in a natural skin. Mr. Dunford enquired as to the possibility of liquefying glues by trypsin or other enzymes, to a definite stage and producing a liquid glue without destroying its adhesive power. The chairman asked why tests could not be carried out on a small scale, identical with trade conditions. Dr. Prideaux enquired whether the conversion of an inactive bate into an active one by calcium ions was due to the formation of a soluble complex with calcium salt similar to casein in milk resulting in the corresponding increase in the dispersion of the enzyme.

In reply Mr. Pickard stated that glues could be liquefied and the resulting glue retained to a lesser degree its adhesive properties; the diminution in adhesive power may be due, however, to such impurities as fats in the enzyme. Satisfactory tests could not be made on small pieces of skin and the skins themselves showed considerable variation in character. A very marked increase in enzyme action is produced by very minute amounts of calcium salts and hence the increased activity could not be attributed to increased dispersion due to the presence of soluble calcium salts.

SOUTH WALES SECTION

On November 7 at the Technical College, Cardiff, Mr. Donald Brown, of the Ely Paper Works, Cardiff, read a paper on paper making. Mr. G. H. Clegg was in the chair.

The lecturer dealt very fully with the details of fibre treatment from tree to finished product. The theoretical aspect of cellulose hydration was considered and also the practical difficulties occurring owing to the variation of this factor. The problem of scientific control was also discussed, and it was pointed out that in the paper-making industry, as in many others, scientific methods of control were only slowly superseding rule-of-thumb methods. The question of paper tinting was dealt with, and the difficulty of securing standard products with English dyestuffs was pointed out. The lecture was amply illustrated by slides and by specimens of papers produced by various processes. In the discussion which ensued the problems of bleaching, silica content of grasses, and the use of loading materials were discussed at length, and the meeting concluded with a vote of thanks to the lecturer for his lucid exposition of the process.

SOCIETY OF PUBLIC ANALYSTS

At the meeting held on November 5, Mr. G. Rudd Thompson, President, in the chair, the following papers were read:—

"On Certain New Methods for the Estimation of Small Quantities of Arsenic and its Occurrence in Urine and in Fish," by H. E. Cox, Ph.D., M.Sc. The methods and results of the Swedish Commission on chronic arsenical poisoning have been carefully tested and the conclusion reached that the nitric and sulphuric acid digestion process described by Bang and Ramberg gives higher and more accurate results than the older wet combustion method adopted by the Joint Committee of the Society of Public Analysts and the Society of Chemical Industry in 1902. The iodine titration method of Bang is not reliable, but Ramberg's bromate method gives satisfactory results if the amount of arsenious oxide to be estimated is not less than 0·01 mg.; below this amount the Marsh-Berzelius process following Ramberg's method of destruction is preferable. It is found that normal urine may contain quantities of arsenic which have been thought to be associated only with chronic arsenical poisoning; amounts present in the urine of persons on known diets varied from 0·0 up to 0·58 mg. per litre. Large excretion of arsenic is due to the eating of fish and it is shown that fish, especially plaice, may contain arsenic up to 3 parts per million. The eating of such fish leads to the appearance of quantities of arsenic in the urine within twenty-four hours.

"Estimation of Cadmium in Brass," by A. T. Etheridge, M.B.E., Ph.D. The preliminary electrolytic separation of copper and lead is effected as described by the author (*Analyst*, 1924, 49, 371). The liquid containing cadmium, zinc and other metals is treated with sulphuretted hydrogen in acid solution, sulphides are taken up, precipitated next in alkaline solution, and again treated as before in both acid and alkaline solution, and a final acid precipitation then leaves pure cadmium sulphide which is weighed after conversion into sulphate. Though the method is tedious, the purity of the product is ensured with great accuracy within 0·05 per cent. cadmium in brass.

"The 'Hoyberg' Method of Milk and Cream Testing," by N. C. Wright, B.A., and J. Golding, D.S.O. The "Hoyberg" method for determination of fat in milk and cream has been tested under carefully controlled conditions against gravimetric estimations. For milk testing the method has been found to give low and variable results, and to be unreliable for routine estimations, particularly in the hands of unskilled workers, for whose use it is chiefly designed. For cream testing, the results show a greater degree of accuracy, the errors being chiefly due to the fact that the cream is measured by volume and not by weight.

"An Apparatus for the Catalytic Dehydrogenation of Alcohols," by Stanley G. Willimott, Ph.D., B.Sc. The usual laboratory methods for the preparation of aliphatic aldehydes are shown to be unsatisfactory. An improved dehydrogenation apparatus is described, the chief advantages being: (*a*) The quantity of alcohol vapour entering the dehydrogenation tube is controlled by regulation of the boiling. The vapour passes through a heated copper spiral, and entering the tube at 300° C. is readily dehydrogenated by the copper catalyst. (*b*) The introduction of the preheater prevents liquid entering the tube with consequent cracking. (*c*) Heating of the air-bath is facilitated by employing an ordinary combustion furnace; asbestos sheeting maintains the temperature uniform.

BIOCHEMICAL SOCIETY

A meeting was held in the Physiological Department, St. Bartholomew's Hospital, E.C.1, on November 10, 1924, when the following papers were communicated:—

"On the Micro-estimation of Urea in 0·2 c.c. of Blood," by Garfield Thomas. 0·2 c.c. of blood removed from the finger is collected in a carefully calibrated pipette, and washed into a test tube with about 0·5 c.c. of water. 0·03 g. of soya bean meal is added, and this is followed by one small drop of caprylic alcohol. The tube is stoppered and placed in a water-bath at 45°—50° C. for 20—30 minutes. On removal, 0·3 grain anhydrous potassium carbonate is added and 0·5 c.c. of a saturated solution of potassium carbonate. Air freed from ammonia is then drawn through the blood into a tube containing 5 c.c. of $N/150\ H_2SO_4$. After 30 minutes the tubes are disconnected and 4 c.c. of the acid solution is removed, and titrated with $N/150$ NaOH, using a micro burette graduated into 1/100 c.c. and having a capillary outlet. Each 1/100 c.c. of sulphuric acid neutralised by ammonia corresponds to 1 mg. of urea in 100 c.c. of blood. A correction of 4 mg. of urea per 100 c.c. of blood is deducted from the value obtained on account of the ammonia liberated from the soya bean.

"The Excretion of Salicyluric Acid after the Ingestion of Sodium Salicylate by the Human Subject," by E. Holmes. Sodium salicylate was taken by the mouth, in single doses of from 2—5 g. The urine was extracted with ether after treatment by alkaline lead acetate and sulphuretted hydrogen. Crystalline material was obtained by this method, which was partly soluble and partly insoluble in hot benzol. The benzol-soluble part was identified as salicylic acid, and the benzol-insoluble portion was identified as salicyluric acid. 57 per cent. to 60 per cent. of the ether extractable salicyl appears as salicyluric acid. This percentage does not vary with the dose over the range of dosage investigated. The figures were checked by the use of Hanzlik's distillation method.

"The Effect of Irradiation of the Environment with Ultra-Violet Light upon the Growth and Calcification of Rats Fed on a Diet Deficient in Fat-Soluble Vitamins," by E. Margaret Hume and H. Henderson Smith. Rats fed on a diet deficient in fat-soluble vitamins cease to grow normally after two or three weeks. Irradiation with ultra-violet light, within approximately the first 90 days on deficient diet, causes a temporary resumption of

normal growth. The authors have previously published a paper showing that the same effect can be obtained when rats are kept in glass jars, which have previously been irradiated, and they then ascribed the growth-promoting effect to the irradiated air present in the jars. Webster and Hill were not able to confirm this result, and the authors have since found that the growth-promoting effect does not occur unless sawdust is present in the jars during irradiation. Sawdust was present in their previous experiments but its possible complicity was completely neglected. When sawdust is present in the jars during irradiation, rats grow as well as ones irradiated directly; when it is not present, the growth is similar to that of untreated controls. Calcification of the bones is found to be directly proportional to the amount of growth in such an experiment.

"The Effect of Insulin on Cholesterolaemia," by G. A. Harrison. Insulin removes the hypercholesterolaemia of diabetes mellitus. Nitzescu and others have shown that insulin does not affect the blood cholesterol of normal dogs. The writer was unable to influence the hypercholesterolaemia of two children by insulin therapy. The first case (age $4\frac{1}{2}$) was suffering from nephrosis, the second (age 9) from non-diabetic xanthoma. Both had normal blood-sugar curves and no glycosuria. The blood-cholesterol in the first varied from 347 to 544 mg. per 100 c.c. plasma with insulin, and 337 to 570 mg. without insulin. The corresponding figures for the second case were 325–496 with, and 444–520 without insulin. The xanthoma nodules, which were rich in cholesterol, were uninfluenced by the insulin (3 weeks treatment). It is concluded that so far there is no evidence against the accepted hypothesis that insulin reduces the hypercholesterolaemia of diabetes indirectly through its action on carbohydrate metabolism.

The following papers were also read:—

"Observations on Glucose and Levulose Tolerance Tests," by R. L. Mackenzie Wallis. "The Carbohydrate Enzymes of Some Starch-free Monocotyledons," by R. E. Chapman. "The Determination of the Molecular Weight of Casein by Millon's Reagent," by W. H. Hurtley. (*a*) "Demonstration of Colour Tests for Cystine"; (*b*) "An Improved Murexide Test," by W. H. Hurtley.

POWER DEVELOPMENT IN CANADA

The Nova Scotia Power Commission has awarded contracts for the hydro-electric development, at Ruth Falls, on East River, Sheet Harbour.

An American syndicate proposes erecting a large cotton mill, at the Grand Discharge, to utilise the cheap power and also plentiful supply of cheap labour which is available in the district.

The British Columbia Electric Railway Co. is installing a second power plant at Alouette Lake. The estimated cost is $2,000,000, and 11,500 h.p. will be developed.

CORRESPONDENCE

THE CHEMICAL SOCIETY

Sir,—Being fully conscious of the very considerable difficulties of the position of the Chemical Society at the present time, and with a genuine desire to avoid captious criticism, I should like to make a few comments on the subject.

It seems to me that members in general must regard their subscription to the Chemical Society as, to some extent, philanthropic, for, if one may assume that the first object of the Society is the advancement of Chemical Science by publication of new work on the subject, it follows that many members must be willing to receive a Journal, the whole contents of which cannot be of interest to them. They are probably not wholly of interest even to the most versatile of the purely scientific members. But to publish the present large output of chemical work, the Society must economise its funds, and there are still ways in which this might be done.

(1) At present, money is wasted in printing abstracts of papers which have already appeared in the Journal itself, so that certain papers are really published twice over, perhaps to the exclusion of others.

(2) The Council, in spite of strong reasons to the contrary, publishes in the Proceedings a long and absolutely useless list of titles of papers which have been received by the Society. This, besides wasting the Society's funds, prejudices these papers in two different ways, because (*a*) the process of publication is now so enormously slow that the appearance of a title in the Proceedings may easily warn an investigator in some other country, where publication is a little more expeditious, to hasten his work and get it out while the British paper is undergoing the very protracted ordeal previous to publication: and (*b*) the Council often attempts to force upon an author certain alterations, chemical or grammatical, to which the author cannot agree. The paper is then very gravely prejudiced for publication in any other journal.

(3) Economy might also be achieved by abolishing the summaries and conclusions which often appear at the end of papers. These summaries at the best are very misleading, since an author often takes a much more sanguine view of his work than do other people, and its seems absurd to print over again at the end of a paper what has already been dealt with in full. In the current (October) number of the Journal the omission of these summaries would save no less than 148 lines—more than three pages—which could quite easily be better utilised.

(4) Another economy might be effected by discontinuing the issue of the abstracts of papers which are to be read at forthcoming meetings of the Society. If funds are sufficient for the purpose, the issue of such abstracts is very useful to those who are able to attend the meeting and wish to take part in the discussion. They are, however, a mere luxury: it is infinitely more important to spend this money on the publication of original work.

(5) Taking account of the facts (i.) that London members are able to use the Society's rooms and

attend the meetings of the Society, and (ii.) that they have easy access to the library, it seems to me very reasonable that they should pay a higher subscription than provincial members, in just the same way that town members usually pay a higher subscription to a club than country members. The raising of the subscription of the London members by, say, 33 per cent., would, I am sure, not be objected to by them, although, when I made this proposal at a Council meeting some time ago, it was surprising, considering the practical nature of the suggestion, how little enthusiasm it aroused.

If, however, the effects of such an increase and of the economies mentioned above were still insufficient to enable the Society to fulfil its proper functions, the best plan is for the Council to face the matter boldly and raise the subscriptions all round—including, of course, the increased rise for London members—to such an extent as would make it possible for the Society to carry on its legitimate work.

But the foregoing suggestions deal merely with matters of immediate importance. If the Council wishes to popularise the Society and gain new members rather than lose old ones, some other fundamental and much more important reforms must be carried out.

(1) In a Society which is supposed to represent the chemical interests of the whole country, the dominance of London members is out of all proportion to their numbers, and it is of the utmost importance that the management of the Society shall be placed as soon as possible on a very much more democratic basis than it is now. At present half and, in effect, more than half—at least of the ordinary members of the Council—are drawn from a narrow circle close round London, and since it is manifestly impossible for provincial members to attend Council meetings as regularly or as easily as those resident in the neighbourhood of London, it is clear that the management of the Society is chiefly in the hands of those London members who really represent only a small minority of the members of the Society.

In addition, this dominance of London interest is greatly favoured by the fact that any alteration of a bye-law, even if approved by the Council, must be passed by a two-thirds majority at a meeting held in London in rooms which, at the best, could only contain about one-twentieth part of the members of the Society, and under circumstances which would make any attempt on the part of provincial members to exert an influence on the affairs of the Society quite impossible. It would only be fair that the number of representatives on the Council for the London district, as distinct from other districts, should be merely in proportion to the number of members resident in these districts.

(2) Another matter which seems to me of considerable importance is the status of the publication committee. The bye-laws of the Society say nothing about a publication committee, and yet the Council annually appoint a committee to which is handed over a very large share of the business of the Society, this committee being virtually elected, for the reasons mentioned above, by the London members of the Council, and it is responsible to nobody. In my view, the Council itself ought to be the publication committee, and if the Council is not able to undertake this vitally important task, representatives should be elected for the purpose, *directly by the members of the Society*.

(3) The delay which occurs at present in the publication of papers communicated to the Society has become a scandal. This is certainly unnecessary, and is merely due to the amazingly inelastic methods which characterise the Society. Even papers which are approved by referees and which ultimately appear in the Journal, practically in their original form, are now taking some five to six months in passing through prolonged and entirely useless editorial ordeals. I believe that this could, to a very large extent, be remedied; but, although suggestions to improve matters in this respect have been made, the Council of the Society seems to be too impervious to new ideas even to give them a trial.

It is to be hoped that other members of the Society will express their views on these matters.

THEORY OF SUBSTITUTION IN AROMATIC COMPOUNDS

Sir,—During a recent discussion (*cf. Chem. and Ind.*, p. 1057), I said that the theory of induced polarities assumed that, when oxygen and nitrogen are both present, the former is the negative key-atom. Prof. Lapworth (this vol., p. 1109) disagrees with this, also (this vol., p. 769) with a similar statement previously made by Prof. Ingold (*Trans.*, 1924, **125**, 93), and bases his objection on a quotation from one of his own papers (*Mem. Manchester Lit. and Phil. Soc.*, 1920, **64**, III, p. 5). This, I find, reads in the original: "These two atoms" (divalent oxygen and tervalent nitrogen) "are as a rule, much more *effective* than the halogens, and when they are in competition, the *influence* of the oxygen usually appears greater than that of nitrogen." (The italics are mine.) Quite obviously, this paragraph merely expresses what Prof. Lapworth considers to be *observed* effects and influence *i.e.*, experimental facts; it does not deal in any way with *postulates* of the *theory*, and, therefore, cannot be adduced either in support or refutation of what Prof. Ingold and I have stated.

The corresponding postulates of the theory can, however, be gathered from publications by Prof. Robinson. Thus (Robinson, *Trans. Faraday Soc.*, 1923, XIX, 506): "Now it seems axiomatic that the more perfect or stable octets will retain their electrons more firmly than neighbouring systems in which the stability factor does not operate so advantageously. Relative high octet stability is, therefore, synonymous with relative electronegativity. As a rough guide it was suggested that the less the electrons are restrained, for example, by functioning as covalency electrons, the more stable are the octets." Further (Kermack and Robinson, *Trans.*, 1922, **121**, 435, note, and 430): "The relative normal

instability of the free electrons of the nitrogen atom accounts for the facility with which it enters into conjugated systems." "Ammonium salts will be more readily formed and more stable than oxonium salts." "The stability of free electrons in an octet appears to be the greater the larger their number, the extreme case being represented by the chlorine ion." "The tendency to form an octet is the greater the more nearly it is formed."

Now, when we compare competing tervalent nitrogen, divalent oxygen and fluorine, we find for the number of free electrons, the relative pre-formation of the octet, and also for the absence of "restraint" of the electrons through absence of "covalency bonds," the sequence :—

$$N < O < F$$

Accordingly, for the "relative stability" of the free electrons, the relative "tendency to form an octet," and the relative electro-negativity, that is the relative *postulated* tendency to function as a key atom when competing, we obtain the sequence :—

$$N < O < F, \textit{always}.$$

If, *actually*, this postulate is fulfilled only "usually" as between nitrogen and oxygen, and "as a rule" not at all between halogen and the other two, this proves, not so much that the critics of the theory of induced polarities are ignorant with regard to it, as that the theory itself is, to say the least, useless.

Prof. Lapworth, finally, asserts, without adducing the slightest proof, that my own theory of aromatic substitution is untenable. Well, I neither hold a brief for my theory, nor am I pledged to it as an article of faith, nor do I regard it in the light of a patent medicine which I must persuade others to swallow, and I am, therefore, in a position to make a sporting offer: My aromatic substitution theory and the theory of induced polarities shall, respectively be abandoned, the former when the *first*, and the latter when the *five hundredth* well-authenticated fact clearly running counter to its postulates will have been pointed out—and remained unanswered.

Fleet, Hampshire B. Flürscheim

PERSONAL AND OTHER ITEMS

The session of 1924–25 has opened in the Honours School of Chemistry at the University of Birmingham with an attendance of thirty-two students. In the Research School of Chemistry there are now twenty-eight post-graduate research workers, an unprecedented number in this department of the University. A Salter Research Fellowship, tenable at the University, has been awarded to V. E. Yarsley, B.Sc., by the Salters' Institute of Industrial Chemistry. A Lord Kitchener Memorial Scholarship has been extended to A. E. Rawson, B.Sc., for research in chemistry and chemical bacteriology. A Priestley Scholarship for chemical research has been granted to A. F. Chrisman, B.Sc.

The Institute of Physics has elected the following corporate members: Fellows—L. F. Bates, J. H. Field, C. Hughes. Associates—D. Gunnaiya, A. Subrahmaniam.

The Perkin Medal for 1924 has been awarded to Dr. H. K. Moore, chief chemist and chemical engineer for the Brown Co., and the inventor of the Moore and Allen electrolytic cell for the production of chlorine and caustic soda.

We are glad to learn that Prof. J. W. Hinchley, who recently underwent an operation for appendicitis, is making satisfactory progress. Prof. Hinchley has long been a tireless supporter of the Society of Chemical Industry and of its Chemical Engineering Group, and also took a leading part in the formation of the Institution of Chemical Engineers. All will join in wishes for his speedy recovery.

We understand that Prof. Liveing is making a satisfactory recovery from his recent accident at Cambridge.

At a meeting of the Council of the Birmingham University, the following appointments were made :— S. H. Edgar, B.Sc., and A. W. Binns, B.Sc., to be Teaching Scholars in the Departments of Chemistry and Electrical Engineering respectively, for the session 1924–25. F. J. Paton, M.Sc., to be Student Demonstrator in the Department of the Bio-Chemistry of Fermentation for the session 1924–25.

The "Smithells Fund"

Owing to the generous support which has been received, the fund raised through the University of Leeds, with the object of signalising the distinguished services of Prof. Arthur Smithells, now totals £2462, of which £1137 was subscribed by the gas industry. The commission to paint a portrait of Prof. Smithells, for presentation to the University, was placed with Mr. Fiddes Watt, R.A., and when this and other expenses have been met, a sum will be available for establishing, in the name of Prof. Smithells and on his advice, a scholarship of approximately £100 per annum within the University. The presentation of the portrait to the University will be made in the Great Hall, at 5 p.m., on November 25, when Prof. Smithells and the artist, Mr. Fiddes Watt, are expected to be present. All subscribers to the fund and the readers of this Journal will be welcome at the meeting.

Pulp and Paper in Canada

The Skeena Lumber Co., Ltd., financed by a syndicate of Minneapolis, U.S.A., capitalists, has acquired the Kleanza Co., Ltd., at Usk, Northern British Columbia, including its extensive forest limits and mineral claims, and proposes to erect a pulp and paper mill on the property.

Copper in Canada

The total production of copper in Canada during 1923 was 86,881,537 lb., or more than double that of 1922 (42,879,818 lb.). The copper refinery of the Consolidated Mining and Smelting Co., at Trail, B.C., was idle throughout the entire year.

The production of metals of the platinum group for the year 1923, in Canada, was as follows :— Platinum, 1217 oz. ($141,826); palladium, 1732 oz. ($138,560); rhodium and iridium, 304 oz. ($45,000). They were derived almost wholly from the nickel ores of Sudbury district.

Celotex Factory in Queensland

American interests have decided to establish a "celotex" factory in Queensland, to cost £300,000, which will probably be the first of several plants to make building material from sugar-cane refuse. The owners will buy sugar-cane waste from the mills at a price between 15s. and 20s. a ton, which it is thought will compensate the mill for its loss as fuel. The Premier of Queensland has invited the principals of Messrs. Dahlberg and Hutchinson, the representatives of the American owners of the patent rights for celotex, to send representatives to Queensland to inspect sites in which the Government will give assistance.

Flax-growing in the United Kingdom

The Board of Trade has appointed a Committee to consider and report on what steps can be taken to bring about the growing of flax seed and flax in the United Kingdom on a commercial scale. The members of the Committee are:—Sir Frank Warner, K.B.E. (Chairman); Mr. W. Norman Boase, C.B.E.; Mr. J. G. Crawford; Sir A. D. Hall, F.R.S.; Mr. A. L. Hetherington; Sir T. H. Middleton, K.B.E., C.B., LL.D.; and Mr. H. Mead Taylor, C.B.; together with a representative, to be appointed later, of the Ministry of Commerce of Northern Ireland. Communications should be addressed to the Secretary of the Committee, Capt. S. E. J. Brady, Board of Trade, Great George Street, London, S.W. 1.

Humidity in Cotton Cloth Factories

The Home Secretary has appointed a committee to consider and report whether any, and if so what, modifications of the existing statutory regulations governing the use of artificial humidity in cotton cloth factories are desirable and practicable. The members of the committee are: J. Jackson, O.B.E. (chairman), L. Bates, J. Cross, Dr. A. W. Crossley, C.M.G., C.B.E., F.R.S., G. Green, Dr. L. Erskine Hill, M.B., F.R.S., J. Hindle, H. Roberts, F. Scarisbrick, C. Speak, J. Stuttard and D. R. Wilson. The secretary of the committee is Mr. T. P. Threlkeld, of 72, Bridge Street, Manchester, to whom any correspondence should be addressed.

Beet-Sugar Industry

Spalding, in the Fens, has been selected as the site of a new beet-sugar factory to be built at a cost of £300,000 by the Anglo-Scottish Sugar Beet Corporation, Ltd. The Fenland soil is admirably suited for the cultivation of beet.

Synthetic Ammonia in France

At the State Powder Factory at Toulouse, a plant for the synthesis of ammonia by the Haber process is being erected and the French Government is negotiating with the Société des Produits Chimiques d'Alais for the erection in the same factory of a plant to produce 120 metric tons a day by the Casale process. The Société de la Grande-Paroisse, however, has instituted proceedings to contest the validity of the Casale patents and it is believed that the Société des Produits Chimiques d'Alais intends to proceed against the former company.

Mineral Output in Tasmania, 1923

The aggregate value of minerals raised during the year was £1,219,546, being an increase of £206,041 as compared with 1922. The principle decreases were in carbide, £70,789; silver, £37,098; and osmiridium, £15,870. The following are the amounts of the various minerals produced in 1923:—Gold, 3,684.124 oz.; osmiridium, 673.423 oz.; silver, 638,601·61 oz.; lead, 4,784.057 t.; copper, 6064·7 t.; tin, 1160·39 t.; coal, 80,718 t.; wolfram, 96,86 t.; shale, 1101 t.; iron pyrites, 11,882 t.; carbide, 3236 t.; and limestone, 100,113 t.

The Ph.D. Degree in Australia

The University of Melbourne is discussing a proposal to establish the degree of the Ph.D. in order to encourage higher studies and research. In Melbourne the encouragement of research has been mainly dependent upon a grant of £2000 a year from the State Treasury. This grant was discontinued during the war, and it was not restored until the University Act was passed. The great influx of undergraduates which followed after the war made it impossible to give any attention to research. The need for students who have been trained in methods of research has increased, however, in Australia, just as it has in other countries, and many of the manufacturing industries will require for their direction, technologists capable of holding their own with the highly trained technologists of competing countries. In order to meet the criticisms that "a cheap doctorate" was being set up, the requirements of the proposed degree are to be "more exacting than those of most of the English Universities," and the standard prescribed is in fact so high that none but a very able student could expect to attain to it.

BRITISH INDIA

Second Sugarcane Forecast, 1924-25

From reports received from provinces and states which contain on an average 93 per cent. of the total area under sugarcane in India, the area is estimated to amount to 2,600,000 acres, compared with 2,787,000 acres at the same time last year, or a decrease of 7 per cent. Conditions have not been quite favourable, but the crop is on the whole reported to be fair.

First Groundnut Forecast, 1924-25

Madras, Burma and Bombay, which comprise 89 per cent. of the total area under groundnut in India, report the total area sown to be 2,163,000 acres (1,687,000 acres in 1923-24). Weather conditions have been favourable and the condition of the crop is reported to be good.

Second Forecast, Sesamum Crop, 1924-25

The total area so far reported for the present season is 3,205,000 acres, as against 3,016,000 acres this time last year, an increase of 6 per cent. The present condition and prospects of the crop are fairly good.

REVIEW

STANDARD METHODS OF TESTING PETROLEUM AND ITS PRODUCTS. Pp. x+100. Report published by the Institution of Petroleum Technologists. London: W. Speaight and Sons, Ltd., 1924. Price 6s.

No one who is technically associated with the petroleum industry could fail to appreciate the work carried out by the Committee of the Institution of Petroleum Technologists in their attempt to standardise the methods of testing.

No one could undervalue the importance of standardisation of tests. The Committee, which was responsible for collecting, comparing and evolving the tests as contained in this volume, was composed of gentlemen of such standing and high attainments in the petroleum industry that the recommended methods of testing are bound to be adopted by all interested in the trade.

If it were not for the fact that, for instance, the distillation test was to be made standard, one might conceivably have some objections as to the somewhat unscientific tolerances allowed, both in temperature and in percentages of distillate taken off, also as to the method of obtaining the initial boiling point of a liquid like petrol, but as long as everyone in the industry carries out the tests by the same standard method it will, presumably, enable the purchaser to compare the values of various petrols without any back thoughts as to variation of tests. On the corrosion test (I.P.T. Serial Designation—G. 32), one notes that the Committee of the Institution of Petroleum Technologists was only concerned with ascertaining the degree of corrosion if the gasolene contains dissolved elementary sulphur or corrosive sulphur compounds. Since, however, considerable quantities of gasoline on the English market contain chlorine compounds with a deleterious effect on steel and iron, the copper dish test would not give the same results, and it would be interesting if the Institution of Petroleum Technologists' Standardisation Committee worked out a method for testing both the percentage of chlorine present and the effect on iron and steel.

N. A. ANFILOGOFF

COMPANY NEWS

CASSEL CYANIDE CO., LTD.

A final dividend of 9d. per share has been recommended by the directors of this company, making, with the interim dividend paid in June last, 1s. per share for the year, less tax, payable on December 11.

LIVERPOOL NITRATE CO., LTD.

The annual report for the year to June 30, 1924, shows a gross profit of £188,235, an increase of £55,628. The net profit was £108,157, after providing for all charges, including stoppage and reopening expenses of £17,342, repairs and renewals £6617, and £21,812 compensation to the nitrate pool. A final dividend of 3s. per share is proposed, making 22½ per cent. on an issued capital of £350,000, compared with 15 per cent. on £292,275, leaving, after writing off properties £24,283, and placing £24,669 to reserve, a balance of £16,704 to go forward, against £18,529 brought in. The reserve now amounts to £150,000, and the share premium reserve is £98,637.

REPORTS

REPORT OF H.M. ELECTRICAL INSPECTOR OF MINES FOR THE YEAR 1923. Mines Department. Pp. 21. H.M. Stationery Office, 1924. Price 6d.

The Report gives a summarised description of the fatal accidents to which the use of electricity was a direct or a contributing cause, that occurred during the year ending December 31, 1923. It also includes certain comments upon the non-fatal electrical accidents and dangerous occurrences covering the same period of which information has been received. The following summary, from the annual returns, shows the position as compared with the preceding year as to the use of electricity at all mines under the Coal Mines Act, 1911:—

	1922	1923
Number of mines at work	2,911	2,902
Number of mines using electricity	1,557	1,598
H.P. motors in use above ground	552,148	611,607
H.P. motors in use below ground	688,026	753,138
Total	1,240,174	1,364,745

During the year 1923, there were 14 fatal accidents, causing the loss of 15 lives, two of which occurred above and 12 below ground.

THIRD ANNUAL REPORT OF THE SECRETARY FOR MINES FOR THE YEAR ENDING DECEMBER 31, 1923, and the ANNUAL REPORT OF H.M. CHIEF INSPECTOR OF MINES FOR THE SAME PERIOD WITH A STATISTICAL APPENDIX TO BOTH REPORTS. Mines Department. Pp. 195. H.M. Stationery Office, 1924. Price 6s. 6d.

This report, which marks the completion of the third year of the existence of the Mines Department, contains in addition to the report of the Chief Inspector of Mines, a review of matters outside his province. Part 1 is devoted to a review of the coal-mining industry during 1923, and of the operation of the National Wages Agreement; and colliery developments, legislation, including the Mines (Working Facilities and Support) Act, 1923, and the Royal Commission on Mining Subsidence, are also dealt with. The mines working under the Coal Mines Acts in Great Britain numbered 2902 and there were 369 mines working under the Metalliferous Mines Regulation Acts, and 5431 quarries working under the Quarries Act, 1894. Workers employed at all mines in Great Britain and the Isle of Man during 1923 numbered 1,236,185, and in addition 74,438 were employed at quarries under the Quarries Act. Of the persons employed at mines, 988,892 worked underground and 247,293 above ground. The numbers of persons killed and injured in accidents was 1387 and 218,891 respectively, the former being 227 more and the latter 28,642 more than in 1922, including

1297 fatal and 212,256 non-fatal accidents at coal mines.

The output of minerals in the United Kingdom is shown in the appended table :—

	1923 Tons		1922 Tons
Coal	276,000,560	..	249,606,864
Iron ore and ironstone.. ..	10,875,211	..	6,836,507
Tin ore, dressed (Black Tin) ..	1,760	..	650
Lead ore, dressed	12,499	..	11,079
Zinc ore, dressed	2,124	..	1,620
Tungsten ore, dressed	2	..	3
Uranium ore	4	..	393
Copper precipitate	138	..	167
Manganese ore	2,021	..	250
Chromite	546	..	595

	1923 Tons		1922 Tons
Minerals for chemical and allied industries ;			
Arsenic (white) and arsenic soot	1,605	..	978
Arsenical pyrites	729	..	354
Iron pyrites	6,908	..	5,669
Bog ore	17,839	..	32,189
Ochre, umber, etc.	10,293	..	9,036
Salt	1,976,796	..	1,871,397
Barytes and witherite :			
(*a*) Not ground	15,402	..	17,672
(*b*) Ground	28,095	..	23,277
Celestine (Strontium Sulphate)	6,346	..	4,711
[illegible]osum	317,676	..	257,460
C[illegible] clay	720,533	..	666,834
M[illegible] lay	18,270	..	12,984
Potters' clay	210,445	..	166,357
China stone	51,343	..	38,921
Felspar	3,246	..	830
Felsite	38,155	..	51,775
Calcspar	9,083	..	6,453
Alum shale	4,859	..	2,487
Soapstone	186	..	50
			lb.
Jet		.	130
			Tons
Oil shale	2,860,633	..	2,603,996
Petroleum	136	..	125
	Cb. ft.		Cb. ft.
Natural gas	100,000	..	100,000
Minerals used in making and steel making and other smelting processes ;			
	Tons		Tons
Fluorspar	49,031	..	33,343
Ganister (including silica rock, silica stone and silica sand used as refractories) ..	591,348	..	279,882
Moulding and pig-bed sand..	430,605	..	195,345
Fireclay	2,120,310	..	1,824,201
Minerals for building and road-making and for all other purposes ;			
Limestone	11,431,552	..	9,418,678
Chalk	3,598,354	..	3,024,448
Sandstone	2,282,858	..	2,140,301
Slate	205,147	..	231,410
Clay and shale	8,500,730	..	6,407,715
Chert, flint, etc.	87,125	..	54,151
Gravel and sand	2,517,354	..	2,058,539
Igneous rocks	6,747,046	..	5,927,964

Coal.—The average commercial pithead price of all coal in 1923 was 19s. 9½d. per ton, or about 1s. per ton more than in 1922, and the average declared value of coal exported for the year was 25s. 2d. per ton f.o.b., or 2s. 7d. more than in 1922. The total quantity of coal shipped abroad was 78 million tons, and of coke 4 million t., greatly exceeding the quantities exported during the previous year. The coal available for consumption in Great Britain was 168¾ million t., including 23¼ million t. used at the mines or supplied to the miners, but not including coal used in making coke and patent fuel subsequently exported. The output of coal was 276,000,000 t. (249,606,864 t. in 1922). With the exception of holiday periods and the period from the end of June to the middle of September, the weekly output of coal never fell below 5¼ million t. : in one week in April, it rose to 5,825,000 t. and in one week in December, to 5,956,000 t.

Iron.—The output of pig iron was 7,440,500 t., from an average of 203 furnaces in blast compared with 4,902,300 t. in 1922, with an average of 132 furnaces, and 10,260,300 t. with 338 furnaces in 1913. During the first six months 439,676 t. was exported, but during the latter half of the year exports fell to 286,150 t., the total for the year being 725,826 t. (excluding ferro-alloys). In 1922 the corresponding figure was 651,079 t., and for 1913, 945,262 t. The steel output for the year was 8,481,800 t., an increase of 44 per cent. on that for 1922. The number of persons employed in the mining and quarrying of iron ore and ironstone at the end of each quarter of the year 1923 . as 15,775, 16,296, 15,488 and 15,413.

Tin.—The production of dressed tin ore ("black tin") for the four quarters of the year showed a progressive increase, being 175 t., 330 t., 527 t., and 727¼ [illegible]., respectively, or a total for the whole year of [illegible],60 t.

Lead.—Of some t[illegible]nty mines in operation during the year, six produced 82 per cent. of the total output of dressed lead ore, which was 12,499 t.

Zinc.—The production of zinc ore (45 per cent. metal) remained small in 1923, amounting to only 2124 t. Although this was an increase of 31 per cent. on the output of 1922, it was only 12·28 per cent. of the production of 1913.

Minerals used in the Chemical and Allied Industries showed almost without exception an improvement in production. The total amount of white arsenic and arsenic soot was 1605 t., and of barytes 43,497 t. The output of oil shale in 1923 continued to improve, the tonnage rising by 10 per cent. to 2,860,633 t.

Minerals used for iron and steel making and other smelting processes.—The returns under the head of limestone and dolomite show that of 11,431,552 t., 3,461,964 t. or 30 per cent. were used for fluxing purposes and 372,760 t. or 3·3 per cent. for refractory purposes. The export of fluorspar remained active.

Part III of the Report deals with health and safety in the mining and quarrying industries, and Part IV with the washing and drying accommodation at mines.

A decree has been passed at Oxford University to make a grant of £3000 towards the expense of erecting a block of buildings between the departments of physiology and bio-chemistry, to act as a lecture room, library and workshop for both of these departments.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech.	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder	£47 per ton.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 10s. per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Copper Sulphate	£25 per ton.
Methylated Spirit 64 o.p.—	
Industrial	2s. 7d.—2s. 11d. per gallon, according to quantity.
Mineralised	3s. 8d.—4s. per gallon, according to quantity.
Nickel Sulphate / Nickel Ammon. Sulphate	£38 per ton d/d. Normal business.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¼d. per lb.
Potass. Chlorate	3d.—4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£3 10s. per ton d/d.
Soda Caustic, solid	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton, carr. paid.
Sod. Bichromate	4½d. per lb.
Sod. Bisulphite Powder 60/62%	£17—£18 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphite conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst.	£9 per ton d/d.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	6½d.—1s. 2d. per lb., according to quality.
Crimson	1s. 4d.—1s. 6d. per lb., according to quality.
Arsenic, Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide	£30—£33 per ton, according to quantity.
Carbon Black	7d.—7½d. per lb. ex wharf.
Carbon Tetrachloride	£60—£65 per ton, according to quantity, drums extra.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes White and Dark	5d.—9½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	£48 per ton, barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£16 5s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Precip. B.P.	£47 10s.—£52 10s. per ton, according to quantity.
Sulphur Chloride	4d. per lb., carboys extra.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep	5s. 1d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

There is a general feeling that the fall in price of acetates during the last few weeks has reached its limit. The tendency is now to stiffen again.

Acetate of Lime—	
Brown	£11 10s. per ton, and upwards.
Grey	£14 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Demand quiet but price steady.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 9d. per gall. Unrefined.
Wood Naphtha—	
Miscible	4s. 9d. per gall. 60% O.P.
Solvent	5s. per gall. 40% O.P. Firmer.
Wood Tar	£4—£5 per ton. Very quiet.
Brown Sugar of Lead	£41 per ton. Steady market.

TAR PRODUCTS

Acid Carbolic—	
Crystals	6½d. per lb. Quiet.
Crude 60's	1s. 8d.—1s. 10d. per gall. Market flat.
Acid Cresylic, 97/99	2s. per gall. Fair business at slightly easier prices.
Pale 95%	1s. 8d.—1s. 11d. per gall. More enquiry.
Dark	1s. 8d.—1s. 10d. per gall. Market dull.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	6½d.—7½d. per gall. Small demand
Unstrained	6d.—6½d. per gall.

Benzole—

Crude 65's ..	.. 7½d.—9d. per gall. ex works in tank wagons.
Standard Motor	.. 1s. 1½d.—1s. 3d. per gall. ex works in tank wagons.
Pure	.. 1s. 5½d.—1s. 7d. per gall. ex works in tank wagons.
Toluole—90% ..	.. 1s. 5½d.—1s. 7d. per gall. More inquiry.
Pure ..	.. 1s. 7d.—1s. 9d. per gall. Small demand for home consumption.
Xylol—Coml. ..	.. 2s. 3d. per gall.
Pure ..	.. 3s. 3d. per gall.

Creosote—

Cresylic 20/24%	.. 8d.—8½d. per gall. Little demand.
Middle Oil ..	.. 5¼d.—6¼d. per gall., according to quality and district. Market firmer.
Heavy Oil ..	..
Standard Specification	

Naphtha—

Solvent 90/160	.. 1s. 3d.—1s. 4d. per gall. Demand good. Higher prices probable.
Solvent 90/190	.. 11½d.—1s. 1d. per gall. Demand maintained.

Naphthalene Crude—

Cheaper in Yorkshire than Lancashire. Demand rather better.

Drained Creosote Salts	£3—£5 per ton. Demand slightly better.
Whizzed or hot pressed	£6—£9 per ton. Demand very poor.

ohthalene—

Crystals and Flaked ..	£12—£15 per ton, according to district.
Pitch, medium soft	.. 42s. 6d.—60s. per ton according to district. Plenty of inquiry. Prospects brighter.
Pyridine 90/160	.. 18s. 6d.—19s. per gall. Steady demand.
Heavy	.. 11s. 6d.—12s. per gall. More inquiry.

INTERMEDIATES AND DYES

Business in dyestuffs has increased considerably and the outlook is decidedly better.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% ..	1s. 7d. per lb.
Acid H.	.. 3s. 10d. per lb. 100% basis d/d.
Acid Naphthionic	.. 2s. 2d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	.. 1s. 1d. per lb. Improved demand.
Acid Sulphanilic	.. 9d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil ..	.. 8d. per lb. naked at works.
Aniline Salts	.. 8½d. per lb., naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base ..	.. 3s. 10d. per lb. 100% basis d/d.
Benzyl Chloride 95%	.. 1s. 1d. per lb.
p-Chlorphenol ..	.. 4s. 3d. per lb. d/d.
p-Chloraniline ..	.. 3s. per lb. 100% basis.
o-Cresol 19/31° C.	.. 4d.—4½d. per lb. Rather quiet.
m-Cresol 98/100%	.. 2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	.. 2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline ..	.. 3s. per lb.
Dichloraniline S. Acid	.. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol ..	.. £85 per ton.
Diethylaniline ..	.. 4s. 3d. per lb. d/d., packages extra, returnable.
Dimethylaniline ..	.. 2s. 2½d. per lb. d/d. Drums extra.
Dinitrobenzene ..	.. 9d. per lb. naked at works.
Dinitrochlorbenzol	.. £84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine ..	.. 2s. 10d. per lb. d/d.
G. Salt.	.. 2s. 3d. per lb. 100% basis d/d.
Monochlorbenzol ..	.. £63 per ton.
α-Naphthol ..	.. 2s. 4d. per lb. d/d.
β-Naphthol ..	.. 1s. per lb. d/d.
α-Naphthylamine	.. 1s. 3½d. per lb. d/d.
β-Naphthylamine	.. 4s. per lb. d/d.
m-Nitraniline ..	.. 4s. 2½d. per lb. d/d.
p-Nitraniline ..	.. 2s. 2½d. per lb. d/d.
Nitrobenzene ..	.. 5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	.. 2s. 11d. per lb. 100% basis d/d.
Nitronaphthalene	.. 10d. per lb. d/d.
p-Nitrophenol ..	.. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	.. 4s. per lb. d/d.
p-Phenylene Diamine	.. 10s. per lb. 100% basis d/d.
R. Salt	.. 2s. 4d. per lb. 100% basis d/d.
Sodium Naphthionate	.. 2s. 2d. per lb. 100% basis d/d.
o-Toluidine ..	.. 10d. per lb.
p-Toluidine ..	.. 2s. 10d. per lb. naked at works.
m-Toluylene Diamine	.. 1s. per lb. d/d

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	.. £45 per ton, ex wharf London, in glass containers.
Acid, Acetyl Salicylic	.. 3s. 1d.—3s. 3d. per lb., according to quantity. Sales steady. Price firm.
Acid, Benzoic B.P.	.. 2s. 6d. per lb.
Acid Boric B.P. ..	.. Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric ..	.. 19s.—21s. per lb.
Acid, Citric ..	.. 1s. 4d. per lb., less 5% for ton lots. Market still weak.
Acid, Gallic ..	.. 2s. 9d. per lb. for pure crystal in 2 cwt. lots.
Acid, Pyrogallic, Cryst.	.. 6s. 9d. per lb. Resublimed quality 8s. per lb. Market firm.
Acid Salicylic	.. 1s. 6d.—1s. 8d. per lb., according to quantity. Slightly firmer.
Acid, Tannic B.P.	.. 2s. 10d. per lb. Forward quotations higher spot value likely to increase.
Acid, Tartaric ..	.. 1s. per lb., less 5%.
Amidol	.. 9s. per lb. d/d.
Acetanilide ..	.. 1s. 10d.—2s. per lb. More enquiry.
Amidopyrin ..	.. 15s. per lb.
Ammon. Benzoate	.. 3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	.. 12s. 6d. per oz. for English make.
Barbitone	.. 13s. 9d. per lb. Slightly lower. Quiet steady demand.
Benzonaphthol ..	.. 5s. 3d. per lb. spot.
Bismuth Carbonate	.. 8s. 6d.—10s. 6d. per lb.
„ Citrate ..	.. 8s. 6d.—10s. 6d. „
„ Salicylate	.. 8s. 6d.—10s. 6d. „
„ Subnitrate	.. 7s. 9d.—9s. 7d. „
	According to quantity. Prices again reduced owing to fall in the metal.
Borax B.P. ..	.. Crystal £20, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	.. Very scarce and dear. Prices uncertain.
Ammonium ..	.. 2s. 1d. per lb.
Potassium ..	.. 1s. 11d. per lb.
Sodium ..	.. 2s. per lb.
Calcium Lactate ..	.. 1s. 7d.—2s. per lb., according to quantity. Fair demand and steady market.

Chloral Hydrate	4s. per lb.
Chloroform	2s. 6d. per lb. for cwt. lots.
Formaldehyde	£48—£49 per ton in barrels, ex wharf London.
Glycerophosphates—Calcium, soluble and citrate free	Fair business passing. 7s. per lb.
Glycerophosphates—	
Iron	8s. 9d. per lb.
Magnesium	9s. per lb.
Potassium, 50%	3s. 6d. per lb.
Sodium, 50%	2s. 6d. ,,
Guaiacol Carbonate	9s. 9d. per lb.
Hexamine	3s. per lb. Forward prices higher.
Homatropine Hydrobromide	25s.—30s. per oz.
Hydrastine hydrochlor	English make offered, 120s. per oz.
Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. ,,
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£25 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	60s. per lb. for December delivery. No spot deliveries available.
Synthetic	26s.—35s. per lb., according to quantity. English make. Increasing demand.
Mercurials	Market very quiet.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	3s. 6d.—3s. 7d. ,,
White precip.	4s. 7d.—4s. 8d. ,,
Calomel	3s. 11d.—4s. ,,
Methyl Salicylate	1s. 10d.—2s. per lb.
Methyl Sulphonal	22s. 6d. per lb. Slightly weaker.
Metol	11s. per lb. British make.
Paraformaldehyde	2s. 8d. per lb. for B.P. quality.
Paraldehyde	1s. 4½d.—1s. 6d. per lb. in free bottles and cases. Supplies plentiful.
Phenacetin	5s. 6d. per lb.
Phenazone	6s. 9d. per lb. Cheaper owing to competition.
Phenolphthalein	5s. 6d. per lb. for cwt. lots. Supply exceeds demand.
Potass. Bitartrate—99/100% (Cream of Tartar)	84s. per cwt., less 2½% for ton lots.
Potass. Citrate	1s. 10d.—2s. 2d. per lb.
Potass. Ferricyanide	1s. 9d. per lb. Quiet.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Steady market.
Potass. Metabisulphite	7½d. per lb., 1-cwt. kegs included. F.o.r. London.
Potass. Permanganate	7¼d. per lb. spot. Forward prices higher.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. 3d. per lb.
Saccharin	[illegible]3s. per lb., in 50-lb. lots.
Salol	[illegible]s. 9d. per lb. for cwt. lots.
Silver Proteinate	9s. per lb. for satisfactory product, light in colour.
Sod. Benzoate, B.P.	2s. 6d. per lb. Supplies of good quality now available.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite—Photographic	£13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	75s.—82s. 6d. per cwt., according to quantity. Quiet market.
Sod. Salicylate	Fair demand. Powder 2s.—2s. 3d. per lb. Crystal at 2s. 2d.—2s. 5d. per lb. Flake 2s. 6d. per lb.
Sod. Sulphide—	
Pure recryst.	10d.—1s. 2d. per lb.
Sod. Sulphite, anhydrous	£27 10s. per ton, minimum 5-ton lots, increasing according to quantity, 1-cwt. kegs included.
Sulphonal	14s. 6d. per lb. Little demand.
Thymol	16s. 9d. per lb. Firmer market.

PERFUMERY CHEMICALS

Acetophenone	12s. per lb.		
Aubepine	15s. 3d.	,,	
Amyl Acetate	3s. 6d.	,,	Much dearer.
Amyl Butyrate	7s.	,,	Dearer.
Amyl Salicylate	3s. 3d.	,,	
Anethol (M.P. 21/22° C.)	4s. 6d.	,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 9d.	,,	
Benzyl Alcohol free from Chlorine	2s. 9d.	,,	
Benzaldehyde free from Chlorine	3s. 6d.	,,	
Benzyl Benzoate	3s. 6d.	,,	
Cinnamic Aldehyde—Natural	18s. 9d.	,,	
Coumarin	18s. 9d.	,,	
Citronellol	17s.	,,	
Citral	8s.	,,	
Ethyl Cinnamate	12s. 6d.	,,	
Ethyl Phthalate	3s. 3d.	,,	
Eugenol	10s.	,,	
Geraniol (Palmarosa)	33s. 6d.	,,	
Geraniol	11s. 6d.—18s. 6d. per lb.		
Heliotropine	6s. 9d.	,,	
Iso Eugenol	16s.	,,	
Linalol ex Bois de Rose	26s.	,,	
Linalyl Acetate	26s.	,,	
Methyl Anthranilate	9s. 6d.	,,	
Methyl Benzoate	5s.	,,	
Musk Ambrette	50s.	,,	Dearer.
Musk Xylol	13s. 6d.	,,	
Nerolin	4s. 9d.	,,	
Phenyl Ethyl Acetate	15s.	,,	
Phenyl Ethyl Alcohol	16s.	,,	
Rhodinol	55s.	,,	
Safrol	1s. 10d.	,,	
Terpineol	2s. 4d.	,,	
Vanillin	25s. 6d.	,,	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.
Anise Oil	2s. 10d. per lb.
Bergamot Oil	16s. per lb.
Bourbon Geranium Oil	35s. per lb.
Camphor Oil	65s. per cwt.
Cananga Oil Java	11s. per lb.

Cassia Oil, 80/85%	.. 9s. 9d. per lb.	
Cinnamon Oil, Leaf	.. 6½d. per oz.	
Citronella Oil—		
Java 85/90% ..	.. 5s. 10½d. „	
Ceylon ..	.. 3s. 8d. per lb.	
Clove Oil	.. 8s. 3d. per lb.	Dearer.
Eucalyptus Oil 70/75% ..	2s. 3d. per lb.	
Lavender Oil—		
French 38/40% Esters	35s. per lb.	Dearer.
Lemon Oil ..	.. 3s. 2d. per lb.	
Lemongrass Oil ..	.. 5s. per lb.	
Orange Oil, Sweet	.. 11s. per lb.	
Otto of Rose Oil—		
Bulgarian ..	.. 40s per oz	
Anatolian ..	.. 18s. per oz.	
Palma Rosa Oil ..	.. 16s. 6d. per lb.	
Peppermint Oil—		
Wayne County	.. 35s. per lb. nominal.	
Japanese ..	.. 22s. 6d. per lb. nominal.	
Petitgrain Oil ..	.. 9s. 9d. per lb.	Dearer.
Sandal Wood Oil—		
Mysore	.. 26s. 7d. per lb.	
Australian ..	.. 18s. 6d. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition not later than January 12th, they are on sale at 1s. each at the Patent Office Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on November 27th.

I.—Applications

Bohme Akt.-Ges. Treatment of materials with liquid. 26,521. Nov. 6. (Ger., 13.11.23.)

Bullen. Drying-cylinders. 26,587. Nov. 7.

Imray (Soc. of Chemical Industry in Basle). Process of making disperse systems. 26,215. Nov. 3.

Ironside. Extraction and adsorber plant. 26,714. Nov. 8.

Pinn. Furnaces. 26,337. Nov. 5.

Testrup, and Techno-Chemical Laboratories, Ltd. Interchange of heat. 26,314. Nov. 4.

Testrup and Thomson. Treatment of liquids. 26,524. Nov. 6.

I.—Complete Specifications Accepted

14,676 (1923). Woosnam. Furnaces. (223,918.)

19,870 (1923). New Eccles Rubber Works, Ltd., and Cox. Containers for storing acids, corrosive liquids, and the like. (223,997.)

26,171 (1923). Heimsoth und Vollmer Ges. Reverberatory furnaces. (206,144.)

27,679 (1923). Dorman, Long and Co., Ltd., Roelofsen, and Lowe. Production of fractional distillation. (224,085.)

32,195 (1923). Serive. Rotary drying and torrefying apparatus. (224,111.)

12,541 (1924). Brown and Son (Huddersfield), Ltd., and Child. Tube mills, rotary kilns, rotary screens, and the like. (224,173.)

II.—Applications

Asphalt Cold Mix, Ltd., and Levy. 26,171. See IX.

Chaney and Neath. Distillation of coal. 26,718. Nov. 8.

Chemical Engineering Co. (Manchester), Ltd., Battersby, and Spensley. Refining or clarifying oils. 26,143. Nov. 3.

Dvorkovitz. Manufacture of hard coke. 26,176. Nov. 3.

Glasgow, Stelfox, and Humphreys and Glasgow. Manufacture of water-gas. 26,196. Nov. 3.

Hartung. 26,320. *See* XXIII.

Harvey and Holford. Dehydrators for treating oils. 26,719. Nov. 8.

Ingman, and Midland Coal Products, Ltd. Manufacture of briquetted fuel. 26,578. Nov. 7.

Rice. Solid fuel. 26,140. Nov. 3.

II.—Complete Specifications Accepted

30,289 (1923). White (General Motors Research Corp.). Fuels for internal-combustion engines. (224,102.)

2694 (1924). Syndikat für Gastorschung. Dry distillation of bituminous fuel. (210,797.)

2760 (1924). Gros. Pyrogenic transformation of acetylene or gaseous mixtures containing acetylene. (211,461.)

13,135 (1924). Spencer-Bonecourt, Ltd., and Gregson. Installations for carbonising coal or other fuel. (224,179.)

IV.—Applications

Bloxam (Akt.-Ges. für Anilin-Fabrikation). Manufacture of quinonoid derivatives of 2:1-naphthophenothiazine. 26,629. Nov. 7.

Carpmael (Farbenfabr. vorm F. Bayer und Co.). Manufacture of dyestuffs. 26,715. Nov. 8.

Johnson (Badische Anilin- u. Soda-Fabrik). Manufacture of vat colouring-matters. 26,530. Nov. 6.

IV.—Complete Specifications Accepted

2379 (1924). Soc. of Chemical Industry in Basle. Manufacture of a thionaphthisatin and its intermediate products. (240,465.)

3548 (1924). Soc. of Chemical Industry in Basle. Manufacture of a thionaphthisatin and its intermediate products. (219,276.)

V.—Applications

Akt.-Ges. für Anilin Fabrikation. Manufacture of lustrous threads. 26,627. Nov. 7. (Ger., 14.11.23.)

Cellon Werke Dr. A. Eichengrün. Production of thin films of cellulose derivatives. 26,329. Nov. 4.

V.—Complete Specifications Accepted

17,125 (1923). Lilienfeld. Manufacture of cellulose solutions. (216,475.)

16,512 (1924). Akt.-Ges. für Anilin-Fabrikation. Manufacture of viscose silk. (220,282.)

VI.—Application

Leontieff. Steaming and ageing textile fabrics etc. 26,183. Nov. 3.

VI.—Complete Specification Accepted

26,158 (1923). British Dyestuffs Corp., Baddiley, Shepherdson, Swann, Hill, and Lawrie. Dyeing acetyl cellulose or fabrics containing the same. (224,077.)

VII.—Applications

Calder, and Chance and Hunt, Ltd. Manufacture of sulphuric acid. 26,435. Nov. 5.

Naamlooze Vennootschap Handelmaatschappij Grikro. Manufacture of zinc oxide. 26,660. Nov. 7. (Ger., 3.12.23.)

Soc. l'Air Liquide, Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude. Manufacture and purification of hydrogen. 26,286, 26,399. Nov. 4-5. (Fr., 3.6.24 and 5.8.24.)

VII.—Complete Specifications Accepted

20,385 (1923). Gaillard. Manufacture of sulphuric acid. (202,629.)

7484 (1924). Kassner. Catalytic oxidation of ammonia. (213,571.)

11,039 and 11,040 (1924). Quartz et Silice. Manufacture of articles in silica glass. (224,163 and 224,164.)

IX.—Applications

Asphalt Cold Mix, Ltd., and Levy. Bituminous emulsions. 26,171. Nov. 3.

Giromard. Manufacture of Portland cement. 26,271. Nov. 4.

Rigby. Manufacture of cement. 26,675. Nov. 8.

Twynam. Manufacture of bricks and tiles. 26,112. Nov. 3.

IX.—Complete Specification Accepted

23,111 (1923). Brown. Prevention of dry rot and wet rot in timber and wood. (224,043.)

X.—Applications

Borchers and Stimson. Manufacture of alloys. 26,465. 26,550. Nov. 6.

British Thomson-Houston Co., Ltd. Methods of treating metals. 26,418. Nov. 5. (U.S., 6.11.23.)

Greenawalt. Method of treating ores etc. 26,424. Nov. 5.

Stimson. Manufacture of alloys. 26,551. Nov. 6.

X.—Complete Specifications Accepted

18,944 (1923). Chemical Treatment Co. Desulphurising iron, steel, ferro-alloys, and other metals. (201,555.)

19,208 (1923). Schmidt. Separating particles of metal from a mixture of metallic oxide and metal. (223,969.)

19,838 (1923). Bengough and Stuart. Protecting surfaces of aluminium or aluminium alloys. (223,994.)

19,839 (1923). Bengough and Stuart. Producing a coloured surface on aluminium or aluminium alloys. (223,995.)

25,584 (1923). Coignard. Obtaining a deposition of chromium by electrolysis. (224,065.)

26,171 (1923). Heimsoth und Vollmer Ges. See I.

26,960 (1923). Metallisation, Ltd. (Meurer'sche Akt.-Ges. für Spritzmetall-Veredelung). Welding aluminium. (206,162.)

XI.—Application

Richards, Wythers, and Siluminite Insulator Co. Electric insulating-materials. 26,224. Nov. 3.

XI.—Complete Specification Accepted

25,584 (1923). Coignard. See X.

XII.—Applications

Chemical Engineering Co. (Manchester), Ltd., Battersby and Spensley. 26,143. See II.

Duclaux. Purification and decoloration of oils and fats. 26,205. Nov. 3. (Fr., 2.11.23.)

Harvey and Holford. 26,719. See II.

XIII.—Applications

Evans. Separation of foreign matter from gum etc. 26,324. Nov. 4.

Phillip. Production of paints, varnishes, etc. 26,639. Nov. 7.

XIII.—Complete Specifications Accepted

19,333 (1923). Risler. Process for obtaining phosphorescence in luminous paints. (207,786.)

19,591 (1923). Consort. f. Elektro-Chem. Industrie. Process of improving resins. (201,916.)

2787 (1924). Evans. Separation of kauri gum from foreign matter. (224,131.)

XIV.—Applications

Falls. Rubber etc. substitutes. 26,382. Nov. 5.

Warren. Production of metallised surfaces on rubber etc. 26,517. Nov. 6.

XVI.—Application

Soc. Chimique de la Grande Paroisse, Azote et Produits Chimiques. Manufacture of fertilisers. 26,401. Nov. 5. (Fr., 13.3.24.)

XVII.—Application

20,048 (1923). Dextrin Automat Ges. Liquefaction and saccharification of starch. (215,705.)

XIX.—Application

Milkal, Ltd., and Sierra. Apparatus for manufacturing milk etc. powder. 26,913. Nov. 3.

XIX.—Complete Specifications Accepted

21,478 (1923). Muller. Desiccation of vegetable material. (224,025.)

22,631 (1923). Stevenson. Preserving milk and other liquids. (224,037.)

XX.—Applications

Fernando. Medicinal compound. 26,295. Nov. 4.

Imray (Farbwerke vorm. Meister, Lucius, und Bruning). Manufacture of water-soluble condensation products. 26,730. Nov. 8.

Imray (Soc. of Chemical Industry in Basle). Manufacture of esters of unsaturated acids. 26,628. Nov. 7.

XX.—Complete Specification Accepted

16,634 (1924). Akt.-Ges. für Anilin-Fabrikation. Manufacture of vanillin. (219,676.)

XXIII.—Application

Hartung. Gravimetric analyses of gas. 26,320. Nov. 4.

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number:—*Australia:* Glassware, chinaware, (503); *British West Indies:* Soap, china and earthenware, (505); *Canada:* Iron and lead pipe, rubber, (508); Oils, (Canadian Government Trade Commissioner's Office, Portland House, 73, Basinghall Street, London, E.C. 2); *France:* Leather, oils, (513); *Germany:* Hardware, (516); Heavy chemicals (517); Pig iron, tinplate, (518); *Netherlands:* Iron and steel, (525).

Notes on Plant and Products.

Messrs. Fullerton, Hodgart and Barclay, Ltd., of Paisley, have received an order from a large firm of soap manufacturers in Germany for a patent double effect evaporator plant for the production of glycerine from spent lyes. Prior to 1914 a similar plant was delivered and erected for the same firm in Dusseldorf; the present order is thus a repeat, but for a larger installation. The present order will make the sixth to be supplied to Germany.

Protection of Industrial Property

In consequence of the accession of Greece to the International Convention for the Protection of Industrial Property, an Order in Council was made on October 9, 1924, applying the provisions of Section 91 of the Patents and Designs Act, 1907, as amended by the Patents and Designs Act, 1914, and the Patents and Designs Act, 1919, to Greece, from October 2, 1924. A copy of the Order may be seen in the Patent Office Library, 25, Southampton Buildings, Chancery Lane, London, W.C. 2.

Similar orders have been made in respect of Syria and Lebanon, owing to the accession of these countries to the International Convention for the Protection of Industrial Property.

PUBLICATIONS RECEIVED

Production of Explosives in the United States during the calendar year 1923, with notes on Mine Accidents due to Explosives. By W. W. Adams. Pp. 32. Technical Paper 358. Price 5 cents.

Die Fermente und ihre Wirkungen. By Prof. C. Oppenheimer, with a section on Physical Chemistry and Kinetics. By Dr. Richard Kuhn. Fifth edition revised. Part III. Pp. 321-48. Leipzig: G. Thieme, 1924. Price $1·90.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council of Pure and Applied Chemistry

which consists of Representatives from

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals and the Royal Agricultural Society.

VOL. 43 NEW SERIES — LONDON, NOVEMBER 28, 1924 — NO. 48

EDITORIAL

NOTABLE feature of modern life is the production of great numbers of books devoted to technical and scientific subjects and ngst these chemistry holds a very large place. o of these books are excellent, some are good, and some are merely indifferent. Milton believed that a good book is the precious life-blood of a master, and in Milton's day, when the audience was sm-ll and very critical, many books doubtless mei ed this description. To-day the audience is so vast and the subjects and the writers about them have become so numerous, that the leisurely transfusion of life-blood into a masterpiece has become impossible. Publishing has become a business, and writing has, too, in a way. Most modern books, even novels, attempt to expound a theory or elucidate a technical problem, and on every side authors are to be found addressing their audience from a special point of view. Few can afford the time or expense to read every book which appears and so most are willing to delegate the work of appraisement to the reviewer. Our reviewers have, in many ways, a difficult task. Usually busy men, they willingly give up a considerable portion of their all-too-scanty leisure to read carefully the works we send them and write down their impressions fairly and conscientiously. We know the trouble they take, how eager they are to discern merit or to reprove error. They have our warmest thanks and, knowing the interest taken in our reviews of books, we are sure that our readers appreciate their service, too. have abundant evidence of the closeness with ch our reviews are read and this has induced us levote considerable space in this issue to review a number of interesting books. For further information we have published some notes on the more important publishing firms, and. as we so often receive requests for particulars of books on chemical subjects, we have printed a list of all the books which have been reviewed in our columns—and this means practically all the books published during the past twelve months. The literature of chemistry is growing so rapidly that some kind of guide is necessary and we believe that this list will be a useful feature of the *Journal*.

* * *

The notes on the various firms which publish chemical books remind us that the public attitude to publishers has changed very much since Longmans were founded two centuries ago. In those days publishers were booksellers and it was customary, when any large work was to be published, for two or three publishers to issue a joint edition. This admixtu of the two sides led people to talk contemptuously of publishers as "booksellers." History relates that Moore was furious because Byron wrote "familiar letters to Murray, a bookseller," and the only defence put forward was that Murray kept his own carriage. It is even recorded that, at a literary dinner held during the Napoleonic wars, a toast to Napoleon was allowed on the grounds that he shot a bookseller. Saner views prevail to-day; and there will be no one to contradict the assertion that chemistry owes much to the publishers of works such as Thorpe's Dictionary, and treatises such as those of Mellor, Cohen, Friend and many others familiar to all chemists. The astonishing variety of subject dealt with in modern books on chemistry is well illustrated by the reviews printed in this number. An encouraging feature, too, is the more philosophic treatment of the problems of our science. There is a growing interest in the history of chemistry, there are valuable treatises on all branches of the science, and there are hopes that co-ordination will be soon within the comprehension of all. Much of this we owe to the enterprise of publishers, who are willing to print highly expensive works that are unintelligible, unfortunately, to the mass of the general public. It is for our readers to see that they are rewarded.

All the scientific societies are now well into the work of the winter session; sections are joining with sections to discuss all kinds of subjects, and there is a stimulating atmosphere of co-operation. The art of the joint meeting is being practised vigorously this winter, and the enthusiast with a taste for meetings, and no dislike for a little travelling, can easily occupy most of his evenings in London, Glasgow or Bristol. Manchester has, of course, long been familiar with the joint meeting and the interesting address delivered there recently by Sir William Willcox shows how valuable such meetings can be. The address, of which we print the major portion, is full of information and very suggestive. It is significant that so distinguished a lecturer should think it worth while to review the historical relations of chemistry and medicine, two sciences which have been closely linked together in the past, and will be still more intimately connected in the future. There is a certain tendency to assume that chemistry is concerned solely with the collection of facts, and that the study of its history serves merely to prevent errors such as the inclusion of a Bunsen burner, dating from 1866, in illustrations of apparatus used by Dumas in 1841 to determine the composition of water. History is useful in this respect, but its true utility is not so readily apparent. It may seem paradoxical to claim utility for non-utilitarian studies such as the dead languages, history or similar subjects. But the fact remains that such studies are of the utmost value in directing the mental outlook. It was at one time customary to advocate the study of history, Latin, or mathematics as a mental training. This does not state all the case; the mental outlook is more important than mere mental agility. Dr. Armstrong, in his presidential address, said that a man acquired a post by his competence, but succeeded afterwards by his ability as a man. Mr. Woolcock, our present president, is, it seems to us, actively pointing a similar moral in his insistence that chemists in industry should consider the manufacturer's problems more closely. It is a question of mental outlook, and the attitude of mind towards a problem will more often determine the success with which it is solved than extensive knowledge, necessary as this is. The investigator who possesses the history of his subject will, with the lessons of the past familiar to him, be unconsciously more prepared to advance than he who possesses the facts of the immediate present and nothing more. The complete chemist will always be more than a chemist, and to show that the question is of more than academic importance, it may be pointed out that the technical staff of more than one large and successful business organisation is recruited solely from those who combine competence with the right mental outlook.

THE INFLUENCE OF CHEMICAL RESEARCH ON MEDICINE AND FORENSIC MEDICINE*

By SIR WILLIAM WILLCOX, K.C.I.E., M.B., F.I.C.

Chemistry at the present day may rightly be described as an exact science. It is only during the last 150 years that it has become so, and it is well to remember what a debt chemistry owes to physics for its present prominent position among the exact sciences. Medicine has been closely linked with chemistry from the earliest times, and each, during their earlier development, has owed much to the other. Medicine, at the present time, may be described as an applied science. Many of its problems have been too difficult for solution beyond possibility of doubt, and theories and speculations still occupy a prominent position in the medicine of to-day. By researches in chemistry and the ancillary sciences many of the problems in medicine are being elucidated, so that as time advances theories and speculations are being gradually displaced by deductions based on exact scientific observations. It is doubtful, however, if medicine can ever possibly become a science characterised by such exactitude as obtains in chemistry. Too many complicated factors play a part in the processes of physiology and disease to render this attainable. It is certain, however, that the application of exact chemical methods to problems of medicine and physiology has done more than anything else to clear away error and to lead to the proper understanding of the difficulties with which they are confronted.

The development of chemistry has been divided into the following periods:—Firstly, the prehistoric period, dating from prehistoric times to 1500 B.C. The next period was the alchemic period of 1500 B.C. to 1560 A.D. It was during this period that scientific workers attempted to transmute metals and that the ancient Indian and Greek natural philosophers conceived their idea of atoms, a conception which was later elaborated and formed the basis of Dalton's atomic theory. During this alchemical period, chemistry appears to have had little relationship with therapeutic medicine, but its association with toxicology was very close. Poisoning and antidotes for poisoning appear to have exerted a great fascination on the human race from earliest times, and they are frequently mentioned in the earliest writings. Xenophon, 410 B.C., relates that the use of poisons was so frequent among the Medes that it was an ancient custom for the cup bearers to taste the wine before presenting it to the King. Criminal poisoning is referred to in Roman history in 331 B.C., when twenty matrons were surprised in the act of preparing a poison which they were compelled by the magistrates to drink and from which they perished. Roman law, 82 B.C., contains an enactment dealing with the crime of poisoning, and a later enactment dealt with the use of poisons for procuring abortion. In the first century B.C. Mithri-

* Address delivered at a joint meeting of the Manchester Sections of the Society of Chemical Industry, the Society of Dyers and Colourists, the Institute of Chemistry and the Manchester Literary and Philosophical Society.

dates was so interested in poisons that he personally conducted toxicological experiments on condemned criminals and others. He wrote a book on the subject, and he invented a universal antidote for poisons which Celsus describes as containing 36 ingredients. It is recorded that when Mithridates, tired of life, wished to commit suicide, his constitution had been so long inured to antidotes that poison had no effect on him. He was, therefore, compelled to ask a Gallic mercenary to despatch him with his sword.

With the renaissance in Italy, poisoning became a fine art, and political murder by poison was *in those days* considered to be quite legitimate, as is evidenced by the secret archives of the Council of Ten at Venice, 1400 A.D. to 1500 A.D. It was in this period that Pope Alexander VI and his son Cæsar Borgia committed numerous murders by poison, and Pope Alexander VI himself fell a victim to poison in 1503, his butler giving him the poisoned wine intended for one of his victims. Poisoning in England was not unknown at this period, and in 1531 A.D. a statute of Henry VIII ordered poisoners to be boiled to death. Up to the nineteenth century criminal poisoning was very common, and probably preparations of arsenic and corrosive sublimate were most commonly used. The methods of diagnosis of poisoning depended mainly upon the supposed circumstances attending the administration. The post-mortem appearances in cases of poisoning appeared to have been very little understood, and importance was attached to signs such as lividity, discoloration of viscera, etc., which we now know to be merely the ordinary post-mortem changes and not in any way characteristic of death by poison. In those days anyone suspected of poisoning stood very little chance of escape.

Toxicology did not really make any great advance until the development of modern chemistry and the application of accurate analytical methods. The only certain signs of poisoning are the identification and estimation by analysis of the poison in the body.

In the third period, the Iatro-Chemical period 1500—1700 A.D., chemical investigations were mainly directed towards the cure of all ills, the *elixir vitæ*. During this period, phosphorus was discovered, and improvements were effected in many processes, such as the making and staining of glass and of earthenware. This period is of value to medicine in the discovery of sodium sulphate by Glauber.

The Phlogiston, or fourth period, from 1660–1775 A.D., marked the efforts to explain the changes occurring in combustion and chemical combination. The work, though much of it was unfertile, paved the way for, and was the precursor of, the next period, which is the Quantitative Period, in which the foundation of modern chemistry was laid.

The fifth and last period, the Quantitative Period, from 1775 A.D. to the present time, marks the development and growth of modern chemistry. Oxygen was discovered by Priestley in 1774, and also independently by Scheele in 1777. Hydrogen was discovered by Cavendish in 1766, and, in his experiments on air, he found that 120th part of air resisted change, thus foreshadowing the discovery of argon by Lord Rayleigh and Sir William Ramsay in 1894. Scheele discovered chlorine in 1774, but thought it was a compound. Gay Lussac, in 1809, and Davy, in 1810, demonstrated the elementary nature of chlorine. Scheele discovered arseniuretted hydrogen in 1775, and hydrocyanic acid in 1783. It is unnecessary to pursue further the numerous discoveries made in the early part of this period by men whose honoured names are household words in the history of chemistry. It is interesting to note that these early workers made use of physiological experiments on animals in their researches.

The foundations of toxicological analysis were laid by the early work of this period. Thus, the Marsh test for arsenic was discovered in 1836, and further perfected by Berzelius. In 1839, it was shown that in certain cases of arsenical poisoning arsenic could be detected in the liver, spleen, heart and muscles, indicating that analysis should be made not only of the stomach and intestines but of the other organs of the body. The importance of the absorption of poisons, and the realisation that it is the absorbed poison which causes death in most instances, was thereby appreciated.

In 1844 Fresenius and Van Walberg devised a method for the systematic research of all poisons and for the destruction of organic matter—viscera—as a preliminary to analysis. This method of analysis is in common use to-day. In 1850, Strauss discovered a process by which alkaloidal poisons could be extracted from viscera, and this process, in a modified form, is one in common use to-day in the toxicological analysis of viscera in cases of poisoning by alkaloids.

We come to modern developments of chemistry. Liebig (1803 to 1873) may be regarded as the founder of organic chemistry. He elaborated the methods of ultimate organic analysis by combustion, and he applied his knowledge to the development of physiological and agricultural chemistry. Liebig's work was the foundation of the chemistry of the proteins and metabolism.

Pasteur was a chemist who had, perhaps, the greatest outlook on science of anyone in history. He is, indeed, claimed as the founder of modern medicine, though he had no official medical qualification. Pasteur's investigations of fermentation led him to the study of bacteriology. He demonstrated conclusively the Germ Theory, and showed, in a famous lecture at the Sorbonne in 1864, that the theory of abiogenesis, or spontaneous generation, advanced by Dr. Bastian in this country, was untenable. He demonstrated that the growth of organisms in sterile culture-media only occurred after these media had been inoculated with living organisms. The truth of *omnia vivum ex vivo* was demonstrated conclusively by his experiment, and this work was fully confirmed by Professor Tyndall in this country. This work of Pasteur led to the study of wound-infection by Lord Lister, and the birth of antiseptic, and, later, aseptic, surgery resulted. The human race owes an ineffable debt of gratitude to Pasteur and Lord Lister for their researches, whereby wounds and surgical operations have been delivered of the dread of infection and countless lives saved.

Pasteur's work on fermentation was followed by masterly studies in silkworm disease, anthrax, vibrio-sepsis and chicken cholera. Pasteur went on from the determination of the cause of disease to discover methods of immunity, and in 1881 he gave a brilliantly successful public demonstration in France of the practical value of his immunising methods against anthrax. He also discovered the means of immunising animals already infected with rabies by the injection of emulsions of the attenuated spinal cords of infected animals. This method is still in use in all parts of the world at the present day, and the discovery is all the more remarkable in that the organism causing rabies has not even yet been isolated.

Passing on from Pasteur, we come to Emil Fischer. He was a chemist to whom modern medicine and physiology owe an enormous debt of gratitude. His work on the proteins led to an understanding of the constitution of the protein molecule, and the methods by which the metabolic processes in the body bring about its synthesis. His discovery of phenylhydrazine led to the foundation of a more precise knowledge of carbohydrate metabolism and diabetes. He discovered veronal, and a host of other new drugs whereby toxicology was greatly advanced.

Paul Ehrlich, another great chemist, by his chemical studies, and their application to medicine, has been one of the greatest benefactors of modern times. His experiments on dyes and tissue-staining led to the discovery of the tri-acid stain whereby the study of histology was greatly advanced. He discovered the Fuchsin stain for tubercle bacilli in 1882 and enunciated a theory of immunity which has been, and still is, the guide-post to numerous discoveries, such as that by Wassermann, of the famous common fixation test for syphilis and other diseases. Ehrlich's name will always be associated with the discovery of Salvarsan and the allied arseno-benzol derivatives, which have been of incalculable value in the treatment of syphilis, relapsing fever, etc. Ehrlich, by his study of the blood corpuscles, consequent on his perfection of staining methods, became the founder of hæmatology.

Modern medicine has become an applied science, and its advance is mainly due to the application of accurate scientific investigation. The chemistry of digestion, the processes whereby renal and skin excretions are effected, the processes of metabolism, all these owe their elucidation to modern chemistry. The fascinating phenomena of internal secretion are essentially chemical processes, and offer a very wide field for further research.

One of the most interesting discoveries of recent times is the isolation of adrenalin, the active principle of the internal secretion of the suprarenal glands. Its chemical and physical properties have been accurately determined, and its physiological action is quantitatively known. It is of interest to note that adrenalin has been artificially synthetised, the synthetic product being known as suprarenin.

What a wide field of research is still open chemistry and biochemistry! The vitamins a most important part in nutrition. Their resist to heat and the methods of extracting them known, but none of them has yet been iso and their chemical constitution is unknown.

As instances of the recent developments in cine, developments which owe their discovery to chemical research, mention may be m micro-chemical processes which enable t protein nitrogen, and the creatinin and ur blood to be determined.

The application of chemical methods wher free and organically combined hydrochlo in the stomach could be determined, and organic acid could be estimated, have be utmost value in medical diagnosis.

Most valuable research on liver disease a Alice has been carried out during the last five or ears. This has been based entirely upon the ch work of Van den Bergh, who discovered a met esti- mating the bilirubin in the serum fr small quantity of blood, the method being d on Irving's discovery of the test for bilirum

Medicine requires all these new tests ve y, very much. As soon as they are all published hey are adopted in all the hospitals in the country. The great debt which modern medicine owes to chemistry, could not be better illustrated than by the isolation, due to Banting, Best, an MacLeod, and their co-workers, of insulin and its use in treating diabetes. The discovery of insulin really depended upon the preliminary chemical work in perfecting the methods of estimating sugar, acetone and diacetic acid in the blood, the carbon dioxide combining power of the blood, and so on. Just as a great victory in war is usually the culmination of steady and painstaking preparation with an object in view, so a great discovery in scientific research is not to be looked for by fortuitous investigations, but rather as the crowning-point of steady and painstaking investigations along carefully thought-out and definite lines.

The perfection of methods of toxicological analysis with which the name of Sir Thomas Stephenson will ever be associated has added greatly to the advancement of toxicology. The application of newly-discovered tests for the alkaloidal and other poisons has been of great importance. For instance, in the Palmer case at Rugeley, in Staffordshire, there is little doubt that it was a case of strychnine poisoning, but at that time (1855) the test for strychnine was not known. The expert for the Crown was unable to say that strychnine was present. From the clinical evidence it seems pretty clear that the death was from strychnine, and Palmer was convicted of murder by poison by strychnine. If that evidence were presented to-day to the Court, Palmer ought to have got off. There is only one proof for poisoning, and that is finding the poison in the body.

The Crippen case was interesting because hyoscin was a very decomposable alkaloid, and that no one could possibly find it in the body after a few days or weeks. Dr. Crippen buried the viscera in quicklime, which helped to preserve those viscera; otherwise I

doubt if the hyoscin would ever have been discovered. It took a month to get out the hyoscin. One dare not go above blood heat; above blood heat the hyoscin would have been hydrolysed. So one had to work, in the extractions and evaporations, at about the temperature of the body, and then one succeeded in getting an alkaloid which gave all the chemical tests for hyoscin.

A great advance in the toxicological detection of arsenic followed the introduction of the electrolytic Marsh-Berzelius test. Before that test was introduced it was rather a nightmare doing toxicological analyses in suspected cases of poisoning by arsenic sometimes, because at one period, just after the War, it was very difficult to get hold of pure zinc. The electrolytic Marsh-Berzelius test has done away with all that anxiety. You may get rather lower results with it, but you get reliable ones, and there is no danger of finding some poison which was not in the viscera. This test was first applied by me for forensic purposes in the "Sutton" case in 1911. I took the precaution of not relying entirely on the Marsh-Berzelius test, and estimated the arsenic in the viscera as sulphide, obtaining enough evidence to say it was a fatal case of poisoning.

Veronal is another substance of very great importance in toxicology which I should like to see abolished from pharmacology. There are an enormous number of deaths from veronal, and many are not diagnosed, because it is thought the death may be due to natural causes. The method of determining veronal is straightforward and simple. It is one that I published in 1913, and I think it has been of use in the analysis of cases of veronal poisoning.

In connexion with the analysis of blood stains, the precipitin test has enabled the medical-legal expert to say not only that the stain of the blood, but the animal species of the blood can, in most cases, be accurately determined. This method has been used by the scientific workers for the Home Office, certainly for the last fifteen years. Toxicological analysis is usually complicated by the presence of organic decomposable matter, and requires experience and care in order that errors may be avoided. It is really a branch of applied chemistry, and requires a great deal of practical experience. It is not a subject that can be lightly undertaken, because the organic matter may lead one astray if one is not alive to this possibility.

A very important function of the medical man and chemist is the giving of evidence in Courts of Law, or before Government Commissions, Departmental Committees, and other public bodies, who are conducting enquiries into subjects of a chemical or medical nature. The enquiries may be of a criminal or a civil nature; whichever it is the function of the scientific witness is the same. The giving of evidence by the scientific witness is one of the greatest privileges and honours which fall to his lot.

It is important to realise that the true function of the expert witness is to assist the Court of Enquiry by his expert knowledge and experience. He is not there to win the case for any particular side. He should not be an *ex parte* witness, and he should be absolutely free from bias. This is supremely essential in criminal cases, but it should be none the less important that in a civil case the expert witness should be absolutely impartial. The giving of scientific expert evidence is a responsibility which should not be lightly undertaken. Statements of fact, on which the enquiry is based, should be carefully considered and examined in a critical spirit. The scientific witness should refresh himself by the most careful study of the literature and scientific knowledge relating to the subject in question. If necessary, he should conduct scientific experiments and investigations to elucidate any difficulties which may arise. An exceedingly interesting example of that is a celebrated "Shampoo" case. Tetrachloride of carbon was at that time popular as a shampoo among ladies, but its use is now forbidden. The vapour was found to be very heavy, and a few breaths of it would prove fatal.

Sometimes before you can form an opinion you may have to do some experiments. The expert witness should turn and turn about in his mind the subject on which he is asked to advise. He should unsparingly cross-examine himself on every aspect of the question. It is of great advantage that an expert witness should imagine himself to be in the position of judge or cross-examining counsel, and to try and view the subject of enquiry from their point of view as well as from the aspect of the counsel on whose side he is engaged. The success of an expert as a witness is much assisted by an appreciation of the psychological attitude of those who question him. This view of things will enable the scientific witness to anticipate the questions which are going to be put to him and it will make him tolerant and charitable to the searching questions of the cross-examining counsel. Before being called upon to give evidence, the expert witness should express his opinion on the facts before him, in a written report, and it is well that the reasons for the opinion should be concisely stated in the report. The opinions expressed in the report should be unalterable views on which the expert has no doubt whatever. In giving evidence, the witness should remember that it is his duty to help the Court by answering questions put to him in a clear, concise, fearless, and audible manner. Many witnesses do not speak up in giving evidence. It is rather bad for the reporters who are present.

In giving evidence-in-chief, the answers should be brief and to the point. In cross-examination, the answers should, where possible, be as concise and clear as in evidence-in-chief. Lengthy explanations and evasions of a direct answer are likely to create a bad impression. A direct negative or affirmative should be given where possible. If this is not possible, the reasons for the inability to give a direct answer should be clearly and curtly stated. Lengthy explanations and attempts to give lectures in the witness box are apt to weaken the evidence, and to raise points of which the cross-examining counsel will not fail to take advantage.

The duty of a witness, whether he is an expert witness or an ordinary witness, is to answer questions put to him by those intended to do so. He should avoid making any statements which are not answers to questions put to him. The expert witness should

avoid giving any answers which are not absolutely free from ambiguity. Thus, for instance, if a question is a double or triple one the witness should ask for the question to be suitably divided so that separate answers may be given to each.

If quotations from books or reports are put to him, the expert witness will be wise to ask to see the works in question, and to give his explanation of the bearing which any written statement has on the inquiry. Generally, when one is confronted with a book some passage is picked out which happens, perhaps, to tell against the evidence one may have given, whereas the whole book is supporting the evidence. Similarly, with statistics and reports.

From a very lengthy experience as a forensic witness, I should like to express my very great appreciation of the courtesy and consideration which are invariably extended by the members of the legal profession to those of our profession. It is the duty and privilege of the expert witness to assist justice by his experience and advice. It is also his duty to ensure that his views are clearly put before the Court, and not one jot or one tittle should be withheld or left in doubt.

To conclude, the relationship between chemical research and medicine is so close that advances in each occur *pari passu*. With the development of bacteriology fifty years ago, and the impetus derived from its application to medicine, chemistry became somewhat overshadowed. There have been clear signs of a great revival in the study of biochemistry during the last ten years, and at present medicine is looking towards chemistry for great and immediate advances. Physical chemistry opens the gates to advances in an untrodden field of medicine and therapeutics. Already, colloidal chemistry is supplying a host of new remedies possessing special attributes owing to their physical state. In the solution by chemical methods of problems relating to disease or poisoning in the body, observations and analyses are often perforce conducted with very small quantities of material. It is for this reason that micro-chemical and colorimetric methods are frequently employed. In doing analysis on a poisoning case you have to work with very small quantities of material, tiny little test tubes, or perhaps even capillary tubes, and to do the tests on small watch glasses.

In chemistry, as in medicine, specialisation of work has become necessary, since the fields of each are so vast. The interest taken by the various chemical societies in this country in biochemical problems, the rapid growth and influence of the Biochemical Society, and the attention given to biochemical problems by the various physiological and pathological societies, are all evidence of the intimate co-operation existing between chemistry and medicine. Pure chemistry has, as its religion, absolute accuracy of work. It is necessary that this spirit of accuracy should be the foundation of all those branches of chemistry applied to medicine. The close co-operation between pure chemistry and those branches applied to medical research is the best safeguard against any dangers from over-specialisation. Biochemistry will be best advanced by the application of the principles of pure chemistry in its work. It is to be hoped that biochemistry will more and more attract to its ranks men who, like Pasteur, have engrained in them the principles and methods of pure chemical science, and who will approach biological problems in that spirit of critical judgment and of experimental investigation which are so essential for great work.

FURTHER DEVELOPMENTS IN PULVERISED FUELS

(From a Correspondent)

Remarkable improvements in the technique of pulverised-fuel firing continue to be made in the United States, one of the latest principles being that of complete automatic control of the working of boiler plant. This is being tried with success on a number of large boilers, notably at the Cahokia power station on the Mississippi at St. Louis and at the Cleveland electricity station. The principle consists essentially in controlling electrically, according to the variation in the actual steam flow, the rate of the feeders which supply pulverised fuel to the burners, together with the height of the damper; that is, a variation in the delivery to the combustion chamber of both the coal and air supplies. At the same time, the ratio between the two is kept constant so as to ensure maximum carbon dioxide and combustion efficiency, irrespective of the amount of coal being burnt.

At the Ford plants, the second installation of four huge boilers of 26,400 sq. ft. heating surface each is now ready to start up at River Rouge, Detroit, and Mr. Cotterell, of the Underfeed Stoker Co., Ltd., states that the plant at Walkerville, Canada, has three boilers of 13,500 sq. ft. heating surface, and is to work in conjunction with the new "Caracristi" process of low-temperature carbonisation, in which a ½ in. layer of roughly pulverised coal travels on a cast-iron plate conveyor swimming on a bath of molten lead at about 1200° F., the carbonisation being said to be complete in five minutes. The residual low-temperature fuel, containing about 10 per cent. volatile matter, is then to be used in the pulverised condition in place of raw coal.

The pioneer plant at Lakeside, Milwaukee, with "Lopulco" pulverised fuel, has now started up the second section of the station comprising eight boilers of 17,500 sq. ft. heating surface, and at the Cleveland Electric Illumination Company, there are four double boilers, each having a total heating surface of 30,600 sq. ft., and ranking therefore amongst the largest in the world, fired with "Lopulco" pulverised fuel from both sides.

With regard to the Allegheny Steam Heating Company of Pittsburgh, with the largest single boiler in the world, 32,750 sq. ft. heating surface, the furnace is designed for a rating of no less than 40,000 lb. to 450,000 lb. of water per hour, that is a ratio of 11 : 1, and the whole operation is extremely satisfactory, giving continuously 15·5 per cent. carbon dioxide.

PUBLISHERS OF CHEMICAL BOOKS

Notes on some of the more important organisations and firms

An account of the more important publishers of chemical books in the English language is no mean matter. Publishers of chemical books do not confine their attention to chemical books; they include in their wide purview other subjects such as gas manufacture, politics, poetry, history, mathematics, fortification, the use of the globes, Persian carpets, ants, beetles, grubs obscure, and wriggling worms. A few of them, but only very few, deal with the law in addition to science; the legal publishers as a rule stick to the law and to what the law produces. Although there are a few firms which make their main business the publication of technical books, for instance, Messrs. Crosby Lockwood and Son and ers. C. Griffin and Co., these are exceptions. quently, a statement about publishers of l books must be nearly as comprehensive as t books and to deal with the books pub- firms in existence to-day does not narrow t very much, for some of the veterans in s go back to the early days of publishers, e days when there was no marked dis- ween a printer and a publisher.

. of our publishing houses are sufficiently e, middle-aged, one might call them without being offensive, for the Oxford University Press was founded in 1468 and the Cambridge University Press in 1521. Those dates were once *fin de siècle*, but surely now belong to the middle ages. Then there are a few firms whose history goes back to the eighteenth century, one of these (Messrs. Longman) to the early part of the eighteenth century, and, of course, there are the new-comers of whom Messrs. Blackie and Son and Messrs. C. Griffin and Co. have now attained years of discretion, having been upwards of a hundred years in bu ness. One of the new upstarts, the firm of Macmillan, has by strict attention to appearances almost attained to respectability, but if the truth were known, and we scorn anything short of the truth, they have merely a beggarly eighty odd years of existence to their credit. We will, however, do them the justice of stating that they have never claimed to be veterans. They have never been ashamed of their youth and inexperience or of anything else, and to the best of our belief we do not know why they should be. As for some of the infants—one firm had the audacity to come into existence in this very century, which is now running —we can hardly consider them as deserving any mention, but they, too, will in time grow up and we will insert a few particulars about all, even those whose birth belongs to this era of short hair, short clothes, short hours of work, and short hours of sleep, shortness of money and of a good deal else.

The Oxford University Press

The first book printed on behalf of the University of Oxford was dated MCCCCLXVIII. Many good authorities consider that 1468 is too early a date, and that an "x" has been accidentally omitted. On the other hand, we may remind our readers that at the time in question the use of Roman figures for dates and in book-keeping was almost universal, except in Italy, and that the omission of an "x" in the date of a publication would have been more easily detected then than now. We do not know the evidence on either side. The University authorities appear in one place to think their Press began in 1478, in another place they appear to think it began in 1468. Whichever date is the correct one, there is no doubt that the Oxford University Press only slowly emerged from obscurity. Early in the eighteenth century the University acquired the copyright of "Clarendon's History of the Rebellion," and out of the profits of this work built the home of the Clarendon Press. They have retained the copyright—so we suppose—to this day; for there are always a few exceptions to every broad principle; and the wind is tempered to the shorn lamb. We think of keeping such an animal as a domestic pet during the ensuing winter, until, say, the end of March. If the experiment is not a success we suppose we must buy a new overcoat, but we are of a sanguine humour. With the encouragement of a Royal Charter or two the Oxford University Press has flourished exceedingly during four centuries; it has published Latin and Greek books in profusion and of these we have a few on our own shelves, including the edition of the "Epistles of Phalaris," of date 1718, and made by Charles Boyle, a relative of the more famous Boyle, who was the father of modern chemistry, and brother of the Earl of Cork. A famous book in its way, too! In accurate and comprehensive dictionaries the Oxford University Press delights: the "Oxford English Dictionary" would do our writing a great deal of good if we had time to go through the bulky volumes with care: and think of Liddell and Scott and the "Lexicon": Schelleri and the "Dictionary of National Biography"! But ever since the day of Boyle's "Phalaris" the University has adopted a high standard before conferring its hall-mark on a work, not only a high standard of printing and paper, but of writing and scholarship. There are certain books of which you could say at once that they would be suitable for the Clarendon Press. We recognised Pollock and Maitland's "History of English Law" as belonging to this class, and Pollo 's "Leading Cases done into Verse" as being altogether too frivolous. But memory being uncertain we turned up the title page of Pollock and Maitland and found it was published by the Cambridge University Press. Well, well; and Pollock was an Oxford professor. The book was good enough to have been published by the Clarendon Press, and that is a compliment to both the book and the Press. The Press has branches in New York, Toronto, Melbourne, Bombay, Edinburgh and Glasgow, and agents in half-a-dozen other cities in different parts

of the world. Among its chemical publications are such well-known works as Monier Williams' "Power-Alcohol," and Morrell's "Varnishes."

The Cambridge University Press

The Cambridge University Press dates from the year 1521. Since then it has steadily grown in importance: John Field who was put in charge of it in the year 1655, showed his zeal by building a new printing-house which remained in use until 1827; his printing room was "sixty feet by twenty, held six presses, had paper windows and a pleasant garden."

The Cambridge University Press was one of the earliest firms to make use of Earl Stanhope's invention of stereotype plates, and bought two presses of his invention in the year 1804.

Oxford has its Clarendon Press; Cambridge, its Pitt Press housed in a building which was erected and paid for out of the surplus cash provided for a statue for William Pitt, a former member of Pembroke College. Oxford was much helped by Archbishop Laud; one of the distinguished men who helped to put the Cambridge Press in order was Richard Bentley. Bentley knew more about Boyle's edition of the "Epistles of Phalaris" than did Boyle or any once since his date. His controversial methods were superb: he was a Yorkshireman: there are no scientific men now alive who could deal with a controversial subject as Bentley did, but if any wish to make the attempt it should be one of

"the sons of Margaret and Clare-hall,
Where Bentley late tempestuous wont to sport,
In troubled waters, but now sleeps in port."

Well, in 1742 we suppose the college port was as soothing as it is now.

The Cambridge University Press has published Bibles, Histories, both Ancient and Modern, many mathematical and physical books including the works of Cayley, Kelvin, Tait and other well-known authorities. We fancy it has not published the works of Newton, a mathematician and physicist of equal repute. Of books more directly interesting to the chemist should be mentioned, Bohr, on "The Theory of Spectra and Atomic Constitution," Rutherford, on "Radio-active Substances," and Whetham on the "Theory of Solution," Liveing and Dewar, "Collected Papers on Spectroscopy," and Muir's "Principles of Chemistry."

The House of Longman

University Presses have many advantages, but they have no pedigree. No-one could write a "Forsyte Saga" about one of them. When we come as we do now to the private firms who publish we are struck by the fact that the businesses are good enough to keep. The writer of these notes has a better knowledge of the lead business than of the publishing business and he notices this common characteristic: each of these industries is sufficiently remunerative to enable a modest man engaged in it to rear a modest family; each is sufficiently respectable to justify the sons and grandsons in continuing to engage in it. Some of the publishing firms have continued in the same family for four, five, or even six generations, some lead smelters and red-lead makers have kept the business in the family for at least a hundred and fifty years. Brewers have amassed money too easily; they tend to become peers and bankers; their sons join the Diplomatic Service. We cannot recall any publisher or any lead manufacturer who became a Viscount; Peers, idle Peers, we know not any who came from these origins.

The house of Longman goes back to the year 1724, when Thomas Longman bought the business which had been Taylor's in Paternoster Row, London. There they are to this day in the very place where "Robinson Crusoe" was published in 1719 by their predecessor, Taylor. Upwards of two hundred years of steady publishing, always improving a little, better type, better paper, better remuneration for the authors, income tax and no doubt finally super-tax for the publishers. Two hundred years the Longmans have been there, two hundred more will bide, very likely. They joined with four other firms in publishing "Johnson's Dictionary," they published all kinds of other books, the "Voyage of the Sunbeam," Macaulay's "History" and Disraeli's novels; so far as we know they are the oldest private publishing firm in the country since, in 1890, they bought up a yet older firm, Messrs. Rivington, founded in the reign of Queen Anne. A casual inspection of a few hundred chemical books leads us to estimate that Longmans have published more chemical books that we should care to have on our shelves than any other firm; "Monographs on Physics," including Lymans' "Spectroscopy of the Ultra Violet," and J. J. Thomson's "Rays of Positive Electricity"; a series of Text-Books of Physical Chemistry, including Findlay's "Phase Rule," Baly's "Spectroscopy" and Desch's "Metallography"; then a series of monographs on Industrial Chemistry, including Morgan's "Organic Compounds of Arsenic and Antimony," Bone's "Coal," Hale's "Electrolysis," Perkin's "Natural Colouring Matters," and several other books fit to be in every gentleman's library; a series of books by Stewart and another series of books by Plimmer, on Biochemistry. Do not allow us to omit Thorpe's "Dictionary of Applied Chemistry," or Mellor's "Inorganic Chemistry." Thorpe and Mellor are the chemist's Bible and Bradshaw, his Routh and Garnett, his Codlin and his Short. If you know your way about Thorpe and Mellor—and Mellor's path is not everybody's path—you can for a long while fare as if you were a chemist. When the Society of Chemical Industry asks us the next time what improvements we can suggest, we shall propose two pages similar to, or identical with, those who now adorn the Duenna, to bring us continually Mellor and Thorpe, which no doubt in their spare time they will read aloud to each other, probably simultaneously; blame them not, they are young.

Messrs. John Murray

John Murray, or Mac Murray, as he was known for a time, bought in the year 1768 a bookselling business at the sign of the "Ship," No. 32, Fleet Street, London. He was a descendant of the old family of Murray of Athol, and had valuable connexions with many interesting and important people in Scotland.

He soon established a reputation as a capable and upright publisher, and was jointly interested in several enterprises with Messrs. Constable and Messrs. Ballantyne. These caused him a good deal of anxiety, and he wisely severed his participation in their affairs before the financial difficulties of these two firms became too acute. When the crash finally came both Constables and Ballantynes were heavily in debt, and Sir Walter Scott, who was also involved, had to devote many years of his life to clearing off his share of the loss by writing some of his most successful novels. Many of these were published by Murray, sometimes in conjunction with Messrs. Blackwood and Constable. Murray also published Byron's poems, Jane Austen's novels, and other standard books. His descendants carried on the business without departing from the high standard set by the original John Murray; they published Lyell's Geology, Darwin's books, the works of Sir Henry Maine, and indeed high-class books in every department of knowledge.

In Science the firm publishes "Science Progress," and the various Bulletins of the Imperial Institute; it also publishes Hall's "Soil," Hall's "Rothamsted Experiments," and many well-known books on agriculture and horticulture. There is usually something stately about Murray's publications, nothing common or mean. Murray's house in Albemarle Street was for many years the resort of the most distinguished writers, travellers and men of note in London.

Blackie and Son

The firm of Blackie and Son, Ltd., is among the grave and reverend seniors of the publishing fraternity, dating from 1809 when John Blackie, senr., took over the previously existing Glasgow publishing house of A. and J. Brownlie. If the Brownlies be reckoned in the Blackie ancestry then the firm may count its birth as having taken place in the last quarter of the eighteenth century.

Glasgow, through its ancient university, has been a centre of culture and learning from mediæval times onwards. The beautifully printed productions of Robert and Andrew Foulis (1750—70)—famous among great printers of all time—bear witness to the quality of the cultural life of eighteenth-century Glasgow. Have we not ourselves a Foulis Homer, a noble folio, a constant source of pride and an occasional source of recreation? The Foulis tradition was continued in Glasgow by Andrew and John M. Duncan, who succeeded Foulis as printers to the university, and, like that great printer, specialised in the production of well executed editions of the classical authors. The Duncans' premises, machinery and type, were purchased by Mr. Blackie in 1819, so that, in a measure, Messrs. Blackie and Son may consider themselves to be in the line of succession from the great Foulis. Certainly they have always sought to maintain the high standard of production in books set by these fathers of the noble art of printing.

The Blackie firm from its earliest days specialised in works of some enduring value as works of reference. Bell's "Glasgow Geography," published in 1812, a complete geographical, statistical and political account of the world in six well-packed volumes, well illustrated and well mapped, is an example. In quite early times there were handsome, richly illustrated editions of works such as Rollin's "Ancient History," "Travels in Italy," by Dr. Moore, father of Sir John Moore who fell at Corunna, "Burns's Poems," "John Bunyan," with text specially prepared by George Offor, still the standard text. Technical and educational publications were also produced by the firm from an early date. Later, when the steam engine had arrived, the changing time is reflected in the firm's catalogue in works such as "Machinery and Mill Work," "The Engineer and Machinist's Assistant," "Railway Machinery," by D. K. Clark, and "The Engineer's and Machinist's Drawing Book" by the same author. Classics are represented by the "Roman Antiquities" of Dr. Adam, Rector of the Edinburgh High School in Sir Walter Scott's day, and by Potter's "Antiquities of Greece." At a rather later period (1836) the works of James Hogg, the Ettrick shepherd, were issued by the firm in a sumptuous edition.

Of purely scientific books the earliest publication of the firm was Comstock's "Natural Philosophy" (1846). Eighteen hundred and seventy saw the issue of Deschanel's "Natural Philosophy" translated and edited by Prof. J. D. Everett. About this time the firm put in hand the preparation of an English edition of the great French dictionary of chemistry, "Wurtz, Dictionnaire de Chimie," Prof. John Ferguson undertaking the editorial control. William Ramsay (afterwards Sir William Ramsay of Argon fame) and James Dobbie (afterwards Sir James Dobbie) were both at that time assistants in the chemistry department of Glasgow University, and were two of the contributors from whom came much good "copy." But, unfortunately, when the work was well under way and the publishers wished to have the first and second volumes got ready for issue it was discovered that many of the articles for the early volumes could not be available until the last French volume was ready. As a result the whole project was relinquished and the work done scrapped, Ramsay's with the rest. Bernthsen's "Organic Chemistry," edited by Prof. Sudborough, formerly of the University College of Wales, Aberystwyth, now of the Indian Institute of Science, Bangalore, is another of the older, though still entirely fresh, chemistry books published by the firm.

In recent years the firm has developed its scientific catalogue very greatly. Dr. R. M. Caven's series, "Manuals of Pure and Applied Chemistry," gives evidence of the firm's activity in the production of works on chemistry, while several volumes of the new series on "Applied Physics" have appeared, and include books and contributions from some of the most eminent men of science.

Gurney and Jackson

This firm was founded early in the nineteenth century. It has specialised in the publication of chemical and other technical books. Messrs. Gurney and Jackson are and have been for many years the publishers to the Chemical Society.

W. H. SMITH AND SON

Two Scotch brothers founded Macmillans in 1843; two English brothers founded Smiths about thirty years earlier. The former became publishers, the latter booksellers and newsagents. From the point of view of success, reputation and honours, it is hard to say which side of the Border has the better record. There are two courses, one for these typical representatives to continue a friendly rivalry: the other course would be to amalgamate the two concerns. We have had to think a great deal about amalgamations during the last few days and may attach undue importance to it as a means of the nation's evolution.

CHARLES GRIFFIN AND CO., LTD.

This century-old publishing house has earned for itself the title of "Makers of Modern Technology." Founded in Glasgow when George III was King, bookselling was combined with the sale of fine chemicals and scientific apparatus. Griffin's Chemical Museum and Griffin's Public Library were well-known establishments and this helped to give the publishing venture in 1820 its scientific and technical bent. "The Glasgow Looking Glass" of 1825 has a quaint advertisement in which a griffin of mythical and heraldic fame is figured serving books in the library.

The publishing branch flourished so abundantly that in 1848 it was transferred to London and became a separate concern under the care of Charles Griffin, grandson of the founder, Joseph Griffin. Members of the family have continued the business ever since and two are now serving as directors, Mr. Charles R. Griffin being a fifth generation. The present chairman and managing director is Mr. Francis J. Blight, F.R.S.E., whose enterprise and efficiency for over a quarter of a century has secured for the house the unobtrusive but solid popularity which has attended the publication of works of world-wide usefulness. Mr. Horace V. Blight, M.C., A.C.A., a director and secretary of the house, was killed in action in France in 1918, and Mr. Arthur Downer, F.I.S.A. (son-in-law of the chairman) has since joined the board of directors.

In 1820 Griffin's published "A Dictionary of Chemistry" by Prof. Andrew Ure, and "An Encyclopædia of Chemistry" with its applications to "Mineralogy, Physiology and the Arts" by Prof. R. Dundas Thomson, F.R.S., and later "The Encyclopædia Metropolitana," "The Circle of Sciences," "Rose's "Manual of Analytical Chemistry," Humphry Davy's "Electro-Chemistry," Faraday's "Lectures on the Chemical History of a Candle," and many other classics. They were the first publishers of "The Chemical News" and they founded "The Year Book of Scientific and Learned Societies," now in its forty-first year of issue and have been responsible for innumerable handbooks and technical treatises, their "Textbook of Inorganic Chemistry," edited by Dr. J. Newton Friend being known to all our readers.

BAILLIERE TINDALL AND CO.

Messrs. Bailliere, Tindall and Co., 8, Henrietta Street, Covent Garden, W.C. 2, who have been established in this country since 1827, are therefore one of the oldest publishing and retailing houses of medical, chemical and scientific books. They issue several catalogues and carry a considerable stock of recent books on chemistry, besides which, it should be noted, they have a Library Supply Department, a Periodical Department and a Foreign Order Department, and can therefore obtain any British or Foreign periodicals and books which may not be stocked. These are useful and time-saving services.

Among their publications are the well-known "Industrial Chemistry Series," edited by Dr. Samuel Rideal, Kingzett's "Chemical Encyclopædia," Barnett's "Anthracene and Anthraquinione." Cross and Cole's "Modern Microscopy," Baker's "Spectroscope," and other standard works.

This firm, also, is agent for Messrs. Williams and Wilkins of Baltimore, who are publishers of some of the most scientific books issued in any part of the world. Among the periodicals they print is *Chemical Reviews*, a new journal appearing under the editorial auspices of the American Chemical Society.

W. AND R. CHAMBERS, LTD.

This business was established in 1832 by William and Robert Chambers in Edinburgh. The founding of "Chambers's Journal" and the launching of that great work, "Chambers's Encyclopædia," are perhaps the most notable features in the firm's history, and these are to this day their most important and popular publications. Among other of their outstanding works are "Chambers's Cyclopædia of English Literature," "Biographical Dictionary," "Concise Gazetteer of the World," "English Dictionary," "Twentieth Century Dictionary," "Organic Chemistry," "Inorganic Chemistry," by Prof. Perkin and Kipping, and other important educational text-books.

CHAPMAN AND HALL, LTD.

The firm of Chapman and Hall, Ltd. have long been noted for their scientific and technical publications, many of which have become standards of reference. It is perhaps of interest to remark that this House, established so long ago as 1837, acted as the original publishers of the immortal works of Charles Dickens. Anthony Trollope was also at one time on the Board of Directors, and George Meredith was for some time reader to the firm.

The literary associations have therefore always been of considerable interest, and the scientific side of the business, established many years ago, is now in process of rapid development.

Chapman and Hall are also well-known as the European and British Empire agents of the old-established firm of John Wiley and Sons, Inc., of New York. Founded in about the year 1807 their catalogue now contains the extraordinary number of over 1000 books, including such household names as Treadwell and Hall, Patterson, and Holleman. Of the famous names which appeared on the general side of the early Wiley list was that of James Fenimore Cooper.

MACMILLANS.

Messrs. Macmillans have published a higher percentage of the books we have in our own small study

than any other publisher and a still higher percentage of our special favourites, such books as "Ball's History of Mathematics," "Lang's Theocritus," "Palgrave's Arabia," "Hajji Baba," "The Gay-Dombeys." It is always a marvel to us that so few people know "Hajji Baba"; if we ever commence business as a publisher the first two books we shall publish will be "Crotchet Castle" and "Hajji Baba"; we scoured London some eighteen months ago for a copy of "Crotchet Castle," but in vain. But we wander from the point. Macmillan's was started by two brothers, sons of a small farmer in the island of Arran, in the year 1843. With assets, which consisted almost exclusively of Highland ancestry and a determination to get on, they bought a small bookseller's shop in Aldersgate Street in the City of London. A few months later they bought a bookseller's shop in Trinity Street, Cambridge, and sold their London shop. The young men made friends with such celebrities as F. D. Maurice, R. C. Trench, E. White Benson, Sir William Thomson, Bishop Colenso and Charles Kingsley and published books on their behalf. If their business methods were similar to those practised by the firm in more recent years it is no matter for surprise that authors of every variety desired their help. In 1858 they bought a business in London, transferred the management of the Cambridge business to one of the Macmillans and a nephew of the name of Bowes, and made London their headquarters. They published the best-known works of such men as Huxley, Stephen, Pater, Trevelyan, Tennyson, Avebury, Geikie, Bryce and Kipling. School books and text books they published for children of all ages and dealing with every subject; these concern us not.

Macmillan's publish "Nature"; we envy the reputation and prestige of "Nature" and yet envy is not a common state of mind with us. They publish "Cohen's Organic Chemistry," "Lewkowitsch's Oils and Fats," "Lowry's Historical Introduction," Nernst, Ostwald, Partington's "Inorganic" and Thorpes' "Historical Chemistry." They also publish Roscoe and Schorlemmer; why say anything about Roscoe and Schorlemmer? One might as well describe the Pyramids or St. Paul's Cathedral. Even editors have a Roscoe and Schorlemmer, perhaps not the latest edition.

Bowes and Bowes

The business which the brothers Macmillan bought in 1843 in Trinity Street, Cambridge, had been founded by one John Nicholson, usually called "Maps," in 1752. After the Macmillans moved to London in 1858 the Cambridge bookselling business remained distinct and was managed by nephews of the Macmillans of the name of Bowes. The present style of the firm is Bowes and Bowes and the chemists who visited Cambridge in 1923 will remember Messrs. Bowes and Bowes' admirable "Guide to Cambridge" and their commodious premises. Books both new and second-hand are there in great numbers and the staff is always glad to search for out-of-the-way books.

H. K. Lewis and Co., Ltd.

The publishing and bookselling business carried on under the name of H. K. Lewis and Co., Ltd. was founded by H. K. Lewis in 1844, in premises at 136, Gower Street, London. Originally devoted mainly to medical and scientific books, the range of subjects gradually extended and the general science and technical sections steadily increased. As the volume of business increased additional space was required, and 24, Gower Place was added. Later the Publishing Department was moved to 28, Gower Place, and this gave much needed room in the main building for the accommodation of the Circulating Library Department, a Reading Room for Subscribers being provided. This change gave room for the opening of a special Department for Scientific Stationery—Card Indexes, Engineering Paper and Drawing Requisites, etc. Arrangements have also been made for keeping customers advised of any publications on subjects in which they are specially interested.

W. Heffer and Sons, Ltd.

Established fifty years ago through the energy and enterprise of Mr. William Heffer, still the head of the firm, the business has undergone constant expansion. In 1897 the Bookshop in Petty Cury, Cambridge, was taken, and the first step in the development of the business was made.

The publishing side at Petty Cury has developed into a vigorous branch of the business, concerning itself mainly, though not exclusively, with books of a technical character, notably science textbooks, and books on the teaching of modern languages. These books are practically all printed and bound at the Printing Works in Hills Road. Of recent years the Printing Works has done a large amount of general printing, including a number of technical and other journals, e.g., *The Analyst*, *The Journal of the Institute of Chemistry*, and *The Secretary*.

B. H. Blackwell

We regret to state that this famous Oxford bookseller and publisher died on October 26 this year. His personality was well known in Oxford, his shop there was, and still is, the resort of many literary men. The firm publishes a number of chemical and other books, including poetry. We notice they publish an edition of the "Poetry of the Anti-Jacobin"; every chemist ought to read this book.

Crosby Lockwood and Son

Messrs. Crosby Lockwood and Son have a very strong selection of Chemical Works, being the publishers of "Industrial and Manufacturing Chemistry" (Organic and Inorganic), in three volumes by Geoffrey Martin, D.Sc., Ph.D., F.C.S., etc. The author's series of Manuals of Chemical Technology are also well-known, numbering eight volumes, amongst which are "Oils, Fats and Waxes," "Perfumes, Essential Oils and Fruit Essences," and "Dyestuffs and Coal Tar Products." Dr. Geoffrey Martin is now engaged in writing "The Modern Soap and Detergent Industry." This work is being published in three volumes. Vol. I, "The Theory and Practice of Soap-Making" being now on the market. Mr.

Scott's "Standard Methods of Chemical Analysis" is, of course, a classic of the industry, but his new "Technical Methods of Metallurgical Analysis" is not so well known. "Chemical Synonyms and Trade Names," by Wm. Gardner, is an important and valuable book which has recently been published, being the first and only compilation of its kind. Messrs. Crosby Lockwood have been appointed agents for the series of Chemical Monographs of The American Catalog Company, of New York, and these valuable works can now be obtained from stock.

Edward Arnold and Co.

The well-known firm of Edward Arnold and Co. was founded over thirty years ago, and has specialised in books of all kinds, especially those of an educational, medical and scientific nature.

German Chemistry Books

Mr. Edward Goldston, of 25, Museum Street, London, W.C. 1, carries a stock of all the latest German Books on Chemistry, and will be pleased to send catalogues and lists regularly to all interested. He claims to have the largest stock of German chemistry books in this country.

J. and A. Churchill

Messrs. Churchill are well known as publishers of books on Natural Science, Hygiene and Medical Science. Their series of text-books of Chemical Research and Engineering includes modern books on emulsions, catalysis, molecular physics and colloids by writers of importance. They publish "Molinari's Chemistry" and "Bloxam's Chemistry." The latter has reached its eleventh edition. "Sutton's Volumetric Analysis" is a standard work, and "Allen's Commercial Organic Analysis" is the last word in such matters. Many of us have had occasion to visit their handsome quarters in Great Marborough Street. None of us has ever regretted a visit.

Methuen

The publishing house of Methuen and Co. was founded in 1889, taking its title from one of the christian names of its originator, Algernon Methuen Marshal Stedman, the son of a Godalming surgeon, who ten years later assumed the name of Methuen. This firm publishes all sorts of scientific books, including Einstein's original book on "Relativity." Indeed, their various books on "Relativity" generally have been recognised as the best of their kind. They also publish books on "Atoms" and the advanced sciences.

Ernest Benn, Ltd.

The publishing business of Messrs. Benn Brothers has grown so much in recent years that their book publishing side has been transferred to a separate company, Ernest Benn, Ltd.

All chemists know Benn's; they publish *The Chemical Age*, "Chemistry in the XXth Century," and pamphlets and books on chemical subjects which have been reviewed in our columns. There is nothing old fashioned or dilatory about the Benns; they are keen, businesslike and enterprising. They are new comers in the chemical world, but they are pushful people who have already become of importance chemically and will become of greater importance. You must keep your eye on Benn; he will keep his eye on you, and if there is any book he thinks you want he will publish it while you are considering how the book should be written. Benn's intend, when they have felt their feet, to make their chemical books as good as their Art books, and that is saying a good deal. They have a knack of doing what they intend.

McGraw-Hill Publishing Co., Ltd.

The publications of the McGraw-Hill Book Co., Inc., of New York, U.S.A., are handled in Europe by the McGraw-Hill Publishing Co., Ltd., of 6, Bouverie Street, London, E.C. 4.

The Book Co. is an amalgamation of the book departments of the Hill Publishing Co. and the McGraw Publishing, both of New York. Both these companies issued technical journals and both had book departments. When the companies were amalgamated in 1907 it was decided to create a separate company for the publishing of technical and scientific books. Every effort was therefore concentrated on the publishing of high-grade books. Readers of *Chemistry and Industry* are no doubt already well acquainted with such leading chemical engineers as Liddell, Clennell, Bogue, Loeb, and Bancroft, also the fine series of uniform volumes under the title of the "International Chemical Series." The metallurgical profession is well catered for by the fine books by Hofman, Peters, Richards and Ingalls, all of which were actually the foundation stones of the big publishing business of McGraw-Hill. *Chemical and Metallurgical Engineering* and *The Engineering and Mining Journal Press* are the two important journals published by this company for the chemical and metallurgical professions.

W. and G. Foyle, Ltd.

This firm started in the year 1904 with no capital except a box full of second-hand books and a few pieces of newspaper. It now has large premises in the Charing Cross Road, London, containing over a million volumes. If a chemist wants a new or a second-hand book of any description Messrs. Foyle will procure it for him.

Wm. Bryce

Mr. Bryce, of 54 Lothian Street, Edinburgh, has one of the largest stocks of books on chemistry and other branches of science in the British Isles. He has shelves full of Technical Journals from *Chemistry and Industry* downwards. He procures you the Alembic Club reprints, which are very good, and many other books which delight the chemist. We know from our own experience how speedily he procures for you what you want.

REVIEWS

A Comprehensive Treatise on Inorganic and Theoretical Chemistry. By J. W. Mellor, D.Sc. Vol. V. Pp. x+1004. London: Longmans, Green and Co., 1924. Price 63s.

The volumes of Dr. Mellor's treatise continue to be published in rapid sequence, and the appearance of the fifth volume is a welcome guarantee that the series will be complete before the early volumes have lost their freshness. The present number is concerned mainly with boron, aluminium, the rare earths and carbon (part I), whereas smaller chapters are devoted to gallium, indium, thallium and scandium. The work is constructed on lines similar to those of the preceding volumes. The subject matter is treated with detail unusual even in large treatises so that the term "comprehensive" is veritably justified. Skilful arrangement, judicious use of type and frequent employment of clear, if small, diagrams combine to render the book not merely an invaluable work of reference, but also a pleasant companion. The bibliography is exhaustive and the ability of the author to include in ordered sequence references to work published during the current year is a striking tribute to the success of his system of working. Most chemists will be grateful also that Dr. Mellor has not been content merely to co-ordinate and arrange a great array of facts but has impressed his personality on the work, even if they regret that he has not included those little touches of philosophy which formed such charming and unique features of his smaller books.

Where all is excellent it is difficult to single out a section for special praise, but the chapter dealing with the rare earths appears to the reviewer to be an outstanding example of the successful treatment of a subject of almost unique complexity.

The book is well printed, and is singularly free from misprints and clerical errors. The only slight drawback to the pleasure of its perusal is the continued use of somewhat inelegant abbreviations and the prolific use of authors' names whereby at times the stage appears so crowded with Hamlets that the interest in the play becomes obscured.

H. Wren

Modern Chemistry, Pure and Applied. By Prof. A. J. Hale. Vol. I, pp. xi+272; Vol. II, pp. vii+276; Vol. III, pp. vii+280; Vol. IV, pp. vii+280; Vol. V, pp. vii+280; Vol. VI, pp. vii+280. London: Virtue and Co., Ltd., 1923. Price, 16s. per volume.

In preparing this compendious work, the object of the author has been to provide for the chemical and general reader a concise account of modern chemistry as it appears, viewed as a whole. With this object in view, examples are culled freely from the academic as well as the industrial sides of the science, and sufficient explanation is given to aid the non-technical inquirer in search of information. Any large general treatise must constantly face the danger of being insufficiently detailed for the technician and too technical for the uninitiated. Although Prof. Hale's treatise is not blameless in this respect, one cannot but admire his perseverance in selecting from such a vast amount of material as that provided by the whole field of chemistry.

Volume I begins with the composition of air and water, opportunity being taken as occasion arises to introduce theoretical matter, passes on to the laws of chemical change, and then on to the non-metallic elements. Volume II reviews the alkali and alkaline earth metals and discusses the properties of dissolved substances, chemical change, the aluminium group, the rare earth elements and the inert gases. Organic chemistry occupies the whole of Volumes III to V, and overruns into seventeen pages of Vol. VI, of which the remainder is devoted to the industrial metals and their alloys, concluding with a chapter on analysis, and a name and subject index occupying 45 pages.

The work is very well printed, but its bulk has been made unnecessarily large by the use of very thick paper, and in view of the arrangement of the contents, the lack of a separate index for each volume, and of some indication of the contents on each back makes handling awkward. Prof. Hale's treatise constitutes a most interesting attempt to review the whole of chemistry, untrammelled by artificial divisions into pure and applied branches, and can be recommended to those who do desire, not an exhaustive treatise, but a much wider range of information than is available in a general text-book.

The Corrosion of Metals. By Ulick R. Evans, M.A. Pp. xii+212. London: Arnold and Co., 1924. Price 14s.

This little book has been written more particularly for three classes of readers, namely, the practical engineer or works chemist, the research worker, and for students of engineering, metallurgy and inorganic chemistry. One feels that to be of real value to the first two of these the book might well have been several times its present size. The problems of corrosion are so vast and intricate that it is impossible to deal adequately with them within the confines of some 200 pages. Many of the sections suffer in consequence from undue compression. To such as have access to a good library this may not be a serious disadvantage, for the book is replete with references which are thoroughly up to date. Mr. Evans has evidently read widely and is to be congratulated upon the large amount of useful material that he has been able to collect together.

After a brief account of the more important theories of corrosion, a chapter is devoted to the direct combination of metals with non-metals, the researches of Pilling and Bedworth, and of Tammann receiving particular attention. After explaining briefly in the third chapter the essential principles of electro-chemistry, the author proceeds to discuss anodic corrosion, corrosion involving the production of hydrogen gas, and, subsequently, the presence of

dissolved oxygen. A section is devoted to the corrosion of copper alloys and condenser tubes, and it is useful thus to have, in tabloid form, a review of the comprehensive researches of Dr. Bengough and his collaborators, as seen from Mr. Evans's standpoint.

In dealing with the prevention of corrosion reference is made to the method of softening water by filtration through permutite, whereby dissolved calcium and magnesium salts are replaced by the corresponding sodium salts. As these have no scale-forming properties and are not subject to hydrolysis, Mr. Evans concludes that they are probably less dangerous from the corrosion point of view (p. 169). This, however, is contrary to the present writer's experience both in the laboratory and in practice, in so far as mild steel is concerned.

The author illustrates in a graphic manner the complexity of the problems of corrosion. "If, for instance, two factors alone had to be considered," he writes, "and ten values of each factor were thought to be sufficient for the tests, clearly 10^2 or 100 experiments would suffice to give the required information. If, however, there are ten factors involved, we should require 10^{10} or ten thousand million experiments. In actual fact the number of important factors is very large."

Mr. Evans is evidently a whole-hearted believer in electrochemical explanations for corrosion phenomena, and the book is written from that point of view. Yet surely in so vast a field there must be many widely different causes for corrosion. One gains the impression that the author, by seeking to tie everything—except perhaps the dry corrosion of metals, with regard to which he appears to have altered his earlier views—down to an electrochemical explanation, to the exclusion of all others, is taking too narrow a view of the subject, and does not quite realise the magnitude of the problem he is so courageously attacking.

The book is attractively written and has been well printed. The grammar is a little weak in places, and the occasional use of such archaic terms as *oxidization* is somewhat cumbersome. But these are minor points, which the author will no doubt remedy in later issues. J. Newton Friend

Outlines of Organic Chemistry. By E. J. Holmyard, M.A. Pp. xii+466. London: Edward Arnold & Co., 1924. Price 7s. 6d.

To one whose chemical training in a University College in this country did not include the preparation of a single organic compound, it is amazing to find how far the teaching of the subject has spread, for the volume before me is written for senior schoolboys and medical students.

It may be, as the author says, a matter of surprise that so little organic chemistry is taught to elementary students. On the other hand, will such a beginner be encouraged with any hope of success "to refer to Beilstein or Richter or the original literature . . . . a detail of training to which great importance is attached." All one can say is that Clifton boys must be well in advance of the ordinary degree student of our Universities, few of whom would—or, in many cases could, even with encouragement—tackle the original German references.

After the first 160 pages these elementary students —beginners, we may suppose—are required to answer such questions as: In what way is the chemical behaviour of phenylnitromethane peculiar? give a brief description of the electronic theory of valency; what explanation of the mechanism of the Friedel and Crafts' Reaction has been advanced? write an essay on the relation between physical properties and chemical constitution of organic compounds and so forth.

These and similar questions are associated in one's mind with an examination paper in the Honours school of chemistry. But this may be mere prejudice, and one naturally turns therefore to the earlier part of the volume to see if the foundations have been well and truly laid, a matter of greater importance than the reading of original references.

There is, to begin with, a full and clear account of the usual methods of analysis and molecular weight determinations. This is followed by what is termed "determination of molecular architecture," and three examples are given, namely, ethyl alcohol, acetic and formic acids. The quadrivalency of carbon is of course insisted on, though the author does not explain why "a free-valency waggling about in space like a tentacle of an octopus is enough to send a cold shiver down the back of an organic chemist"—a didactic form of statement which in the case of beginners would, I imagine, convey little meaning. How are the three examples treated? The usual chemical changes and equations are given, the action of sodium, of phosphorus chloride, etc., but there are no practical details to help the student to visualise these changes or to realise how we know that the products in question are formed. This section is completed in 15 pages. Then follows a short chapter on radicals, when we come to Part II on stereoisomerism, tautomerism, the valency of carbon and catalytic reactions, after which the systematic treatment of aliphatic and aromatic compounds is begun.

The book is written in a clear and lively style, which will appeal to boys, with occasional bits of history, and is embellished with the portraits of distinguished chemists. For a University student with some experience of practical work it can be warmly recommended. J. B. Cohen

Gelatin in Photography. Vol. I. By S. E. Sheppard, D.Sc. Monographs on the Theory of Photography from the Research Laboratory of the Eastman Kodak Company. New York: D. Van Nostrand Company, 1923. Price $2.50.

The importance of as complete a knowledge as possible of the properties of gelatin is well recognised in the photographic industry and any work which promises to increase knowledge in this direction is eagerly looked for and scrutinised. The present volume, the third of the Monographs on the Theory of Photography issued by the Kodak Company, belongs to the category of books that promise much but

equally leave much to be desired. It would appear that the author has attempted too much in too small a space. The historical résumé with which the book opens is but little more than a catalogue of names, dates, and processes, and the fourteen pages it occupies could have been better employed in the amplification of some of the later, more purely scientific matter.

The chapter on manufacturing processes is too long and ill-balanced for a mere sketch, and is far too short to permit of a useful discussion of those factors which are of the greatest practical importance to the photographic manufacturer. The references to original papers are very comprehensive and cover practically the whole field dealt with, and this is true not merely of this section, but of the whole book. On the other hand, the space of seventy odd pages devoted to the review of gelatin manufacture is obviously inadequate, if the many problems involved are to be usefully discussed, and one is left with a feeling of dissatisfaction.

Quite the best chapter in the book is that on the analytical and constitutional chemistry of gelatin, though it is by no means free from matter calling for comment. Exception may surely be taken to the method of determining sulphurous acid by direct titration with $N/10$ iodine. It is now well recognised that gelatin has an iodine absorption value, which varies with different gelatins and is independent of any sulphurous acid content. This is hinted at vaguely on p. 115, where the author says, "Some gelatins, however, evidently contain something beside sulphurous acid which combines with iodine, not always formaldehyde." Again on p. 116 it is stated, "The direct iodine number has a certain value but is not simply a measure of sulphurous acid in gelatins." One would think that two such statements occurring so close together at least called for discussion, if not reconciliation. This example is typical of a number of others, which are open at least to the criticism of loose writing.

No analyst would use the statement made at the bottom of p. 120 as an adequate description of a phosphorus determination. Nor can one agree with the remark (given as a footnote on p. 118) that exact conditions for the ammoniacal silver nitrate test cannot be given because the specifications will vary according to the particular photographic use of the gelatin. The importance of the test may not be doubted, but the conditions of the test must be specified very exactly, and some discussion of the nature of the materials in gelatin which render the test possible, and which make it of value would have been welcomed.

Under the physical testing of gelatins, the more important points are mentioned, but insufficient emphasis is laid on those details which are of most importance in evaluating gelatins for photographic purposes, *e.g.*, p. 207, Fig. 41 shows what the author calls a viscosity—jelly strength curve, but which one would prefer to look upon as a viscosity cooling curve, since viscosity is plotted against temperature. Such curves are of the highest value to the photographic manufacturer, because with practice they indicate what a gelatin is likely to do under actual working conditions. This point appears to have been entirely overlooked in the volume under review. No mention is made of the necessity of allowing the gelatin solution or dispersion to attain equilibrium before proceeding to determine its viscosity, though neglect of such a precaution is a fruitful source of anomalous results.

The volume is disappointing, though much may be due to the inadequate space available: it is at times even irritating, when for example one finds the name Procter spelt in two different ways on the same page. There are fortunately few substances so difficult to investigate or so protean in form and character as gelatin. Equally, there are few substances that have been more strenuously investigated during the past decade. One cannot but expect that a monograph devoted to these aspects of the material should convey this newer knowledge concisely and clearly. Such a monograph is urgently needed, and few are better equipped for such a task than the author of this work on gelatin. It is to be hoped that changes will be made in any subsequent edition so that the work shall more truly represent the standard of the Kodak Research Laboratory at Rochester, and the real knowledge of the writer of the book.

H. W. Greenwood

I. Michael Faraday. By W. L. Randell. Pp. 187. The Roadmaker Series. London: Leonard Parsons, 1924. Price 4s. 6d.

II. The Life of Sir William Crookes. By Dr. E. E. Fournier d'Albe. With a Foreword by Sir Oliver Lodge, D.Sc., F.R.S. Pp. xix+413. London: T. Fisher Unwin, Ltd., 1924. Price 25s.

III. The Life of John William Strutt, Third Baron Rayleigh. By his son, R. J. Strutt, Fourth Baron Rayleigh. Pp. xi+403. London: E. Arnold & Co. 1924. Price 25s.

Biography is a fascinating art, and in proportion to its fascination so the rules mount up for the guidance or confusion of biographers. Dr. Johnson held that a man's life was best written by himself, and when this condition cannot be fulfilled one must ask, at least, that the subject of the biography be made to live in the brief space of the book. The three biographies under review exhibit three different ways of approaching the problem.

I.—The author of this life of Faraday, realising that previous biographies had been mainly concerned with the scientist, has desired to make a clearer picture of the man himself. In this he has well succeeded, and the qualities of Faraday are well brought out, sufficient mention being made of his researches to show their importance. We see Faraday, the errand-boy, promoted to book-binding, his tireless efforts at self-education, and the romantic conditions under which he became assistant to Humphry Davy at the Royal Institution. An interesting account is given of the period of travel on the Continent as valet-assistant to Davy, and a chapter on the state of science in 1791 provides an

introduction to Faraday's researches, which culminated in the production of the first electromotor and his pioneer work on electrolysis. The manifold activities that filled the remaining years of his life are well described, and the book concludes with an appreciation of his qualities, his modesty and lovable character, and his dislike of hypothesis and love of experimental research—a quality which explains the almost unvarying accuracy of his deductions. The author is rightly fascinated with his theme, and has produced a most readable little book, which, as it is also well presented, will make a pleasant companion during a winter evening.

II.—The life of Sir William Crookes is of unusual interest, not only as a record of scientific achievement, but also for the enigma presented by the man. Sir Oliver Lodge, in his foreword, says that "in his (Crookes') presence one did not feel the worshipful enthusiasm which some of the great men of science have aroused," and further implies that "the brilliance of Crookes' discoveries," rather than his personal qualities, "forced him into the highest official position a scientific man can attain"—the presidency of the Royal Society. In addition, his activities in the world of finance and in the much less substantial world of spiritualism are unusual elements in the life of a great chemist.

As far as possible Dr. Fournier d'Albe has allowed Crookes to tell his own story, utilising correspondence freely as well as extracts from his writings. A clear picture is given of Crookes' student days under Hofmann, and of the peregrinations that led to the establishment of the *Chemical News*, which Crookes edited whilst carrying out researches and acting as a consultant. His work in spectroscopy that led to the discovery of thallium is interestingly described, and a fair account is given of the controversy with Lamy over priority in the discovery. After gaining his F.R.S. in 1863, Crookes passed through a troubled period, and his time was occupied with the use of carbolic acid as a disinfectant, the recovery of gold by the amalgamation process, and many lawsuits. These lawsuits and numerous appearances in the courts as an expert witness gained for Crookes a reputation for pugnacity, an aspersion which he indignantly repudiated. His work on the atomic weight of thallium bears witness to his unwearied patience, his accuracy, and his ingenuity in dealing with difficulties. Perhaps the culminating point of his career came with the British Association address on "radiant matter," but a chemist who could claim credit for the discovery of thallium, the radiometer and cathode-ray phenomena, as well as for speculations on the origin of the elements that were far in advance of his time, had no reason for dissatisfaction.

The book gives a vivid picture of the career of a most unusual personality, and yet leaves one—despite its undoubted interest—with a vague dissatisfaction. It is difficult to say whether the cause lies in Crookes' personality and his dealings in *haute finance*, or in the somewhat detached attitude of the biographer. It is certain, however, that the book should be on the shelves of every chemist, because it faithfully describes the work of a great pioneer in chemistry.

III.—It was laid down by Dr. Johnson that only those that live with a man can write his life with exactness and discrimination. This condition is fulfilled by the admirable life of the late Lord Rayleigh which has been prepared by his son, himself a distinguished physicist.

Lord Rayleigh was born with great advantages, and almost from the first he was successful, his reputation being made by his first book, a treatise on sound, published at the age of thirty-three. Despite the claims due to his social position, his one end was the pursuit of knowledge, an aim which he followed with entire devotion. Honours poured upon him, but he remained always a simple, modest gentleman, whose strongest affirmation was "I think you may take it . . . . " when asked for an opinion. Of the romantic his life held little; he was not imaginative or artistic, but he had a remarkable mind, and his son has, with tact and sympathy, enabled us to watch its workings.

Chemists will at once turn to the account of the discovery of argon, and they will find it remarkably clear and interesting. The author is particularly successful in showing how Sir William Ramsay became a co-partner in the discovery, both scientists emerging with credit from a delicate position. The logical beauty of the steps which led Lord Rayleigh from his inquiry into the reason for the apparent departure of the atomic weights from whole numbers to the discovery of argon is well brought out, and the consequences of the work—the arc process of fixing atmospheric nitrogen, the discovery of the inert gases and Aston's work on isotopes—are lucidly explained. For Rayleigh's work on sound, the diffraction grating, the spectroscope, and electrical standards, his collected scientific papers must be consulted, but sufficient account of them is given to make the biography a true picture of the man. Rayleigh was a physicist, but his life is full of interest for chemists. Did he not say, "If you want a thoroughly troublesome job, take up some chemical problem," and did he not relate with relish that Pepper, lecturing before Queen Victoria, said, "The oxygen and hydrogen will now have the honour of combining before your Majesty?" The life of Lord Rayleigh is a fascinating book that should be widely read.

NOTES FROM CANADA

The total revenue of the Hydro-Electric system of Ontario in 1913 was $2,017,439, whereas in 1923 it was $17,219,044, an increase of 557·9 per cent.

The Chemistry department of Laval University, Quebec, has moved into the new building. The late Sir William Price gave $25,000, the income from which is to be used to provide bursaries for students. He also gave $25,000 to the department funds.

At the Royalite No. 4 well, near Black Diamond, in Turner Valley, about fifty miles south-west of Calgary, Alberta, the Imperial Oil Co. has struck a very heavy flow of rich gas at 3740 feet. The flow is 20,000,000 cub. ft. a day, and the gas has a high oil content.

TIMM, J. A. Charts of the Chemical Reactions of the Common Elements. Pp. ix+81. New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1924. Price 10s. (Sept. 26, 1924.)

WARREN, C. A. Brewing Waters. Pp. 114. Reprinted after revision of a series of articles from the *Brewing Trade Review*. London: *The Brewing Trade Review*, 1923. Price 10s. (Jan. 25, 1924.)

WILLSTÄTTER, R. Handbuch der Biologischen Arbeitsmethoden. Lieferung 117: Die Blattfarbstoffe. Pp. 70. Berlin: Urban and Schwarzenberg. Price 3·40, Swiss francs. (May 9, 1924.)

COLLOID CHEMISTRY

BOGUE, R. H. The Theory and Application of Colloidal Behaviour. Vol I, Theory. Pp. xxx+444. Vol. II Applications. Pp. xxvii+445–829. New York: The McGraw-Hill Book Co., 1924. Price £2. (Oct. 10, 1924.)

FREUNDLICH, H. Grundzuge der Kolloidlehre. Pp. viii+157. Leipzig: Akademische Verlagsgesellschaft, 1924. Price 6 g.m. (May 23, 1924).

FREUNDLICH, H. Kapillarchemie: Eine Darstellung der Chemie der Kolloide und Verwandter Gebeite. Third edition, enlarged. Pp. xvi+1225. Leipzig: Akademische Verlagsgesellschaft, 1923. (Jan. 18, 1924.)

FREUNDLICH, H. Kolloidchemie und Biologie. Pp. 47. Theodor Steinkopff, Dresden und Leipzig, 1924. Price $0·50. (Aug. 29, 1924.)

LIESEGANG, R. E. Chemische Reaktionen in Gallerten. Pp. 90. Dresden and Leipzig: T. Steinkopff, 1924. Price $0·85 net. (Sept. 19, 1924.)

MEUNIER, L. Chimie des Colloides et Applications Industrielles. Pp. 336. Paris: Librairie J.-B. Bailliere et Fils, 1924. Price, bound, 40 frs., paper, 30 frs. (April 25, 1924.)

OSTWALD, W. Licht und Farbe in Kolloiden. Pp. xiv+556. Dresden and Leipzig: T. Steinkopff, 1924. Price. $7·60 net. (Sept. 19, 1924.)

OSTWALD, WOLSKI and KUHN. Manipulations de Chimie Colloidale. Translated by Edmond Vellinger. Pp. xviii+201. Paris: Gauthier-Villars et Cie., 1924. Price 6·50 fr. (April 25, 1924.)

SVEDBERG, THE. Colloid Chemistry. Pp. 265. New York: The Chemical Catalog Company, 1924. Price $3. (April 25, 1924.)

PHYSICAL CHEMISTRY

BENRATH, A. Physikalische Chemie. Pp. viii+107. Dresden and Leipzig: T. Steinkopff. Price, paper, 2s. (Aug. 1, 1924.)

DESCROIX, L. Tables Annuelles de Constantes, etc., Art de L'Ingénieur et Métallurgie. Pp. 154. Paris: Gauthier-Villars et Cie., 1922. Price 40 francs. (Nov. 23, 1923.)

GERLACH, W. Materie, Elektrizität, Energie: Die Entwicklung der Atomistik in den Letzten zehn Jahren. (Wissenschaftliche Forschungsberichte. Vol. VII.) Pp. viii+195. Dresden: T. Steinkopff, 1923. Price 3s. 3d. (Dec. 7, 1923.)

GIBBS, W. E. Clouds and Smokes: The Properties of Disperse Systems in Gases and their Practical Applications. Pp. xiii+240. London: J. and A. Churchill, 1924. Price 10s. 6d. (May 30, 1924.)

GUA, M. Trattato di Chimica Fisica. From the fourth American edition by H. C. Jones. Pp. xxiii+731. Milan: U. Hoepli, 1923. Price 56 lire. (July 18, 1924.)

HILDEBRAND, J. H. Solubility. American Chemical Society Monograph Series. Pp. 206. New York: The Chemical Catalog Co., 1924. Price $3. (May 16, 1924.)

LEWIS, G. N., and M. RANDALL. Thermodynamics and the Free Energy of Chemical Substances. Pp. xxiii+653. London: McGraw-Hill Publishing Co., Ltd., 1923. Price 25s. (Dec. 7, 1923.)

LEWIS, G. N. Valence and the Structure of Atoms and Molecules. Pp. 172. American Chemical Monograph Series. New York: The Chemical Catalog Co., Inc., 1923. Price $3. (Jan. 4, 1924.)

McEWEN, B. C. Properties of Matter. Pp. vii+316. London: Longmans, Green and Co., 1923. Price 10s. 6d. net. (Dec. 7, 1923.)

PARTINGTON, J. R., and W. G. SHILLING. The Specific Heats of Gases. Pp. 252. London: E. Benn, Ltd., 1924. Price 30s. (Aug. 8, 1924.)

PERRIN, J. Die Atome. Pp. xx+207. Dresden and Leipzig: Theodor Steinkopff, 1923. Price 5s. (Jan. 11, 1924.)

The Physical Chemistry of the Photographic Process. A General Discussion held by the Faraday Society, in May, 1923. Pp. 241+406. London: The Faraday Society, 10, Essex St., Strand, W.C. 2., 1923. Price 12s. 6d. (Jan. 25, 1924.)

THOMSON, J. J. The Electron in Chemistry. Pp. 144. Philadelphia: The Franklin Institute, 1923. Price $1.75. (Nov. 2, 1923.)

WALDEN, P. Molekulargrossen von Elektrolyten in Nichtwassorigen Losungsmitteln. Pp. 350. Dresden: Theodor Steinkopff, 1923. (Jan. 11, 1924.)

ANALYSIS

Clowes, F., and J. B. Coleman. Quantitative Chemical Analysis. Twelfth edition. Pp. vii+576. London: J. and A. Churchill, 1924. Price 18s. (March 28, 1924.)

Gill, A. H. Oil Analysis. Tenth edition, revised. Pp. 223. London: J. B. Lippincott, 1923. Price 10s. 6d. (Dec. 28, 1923.)

Keane, C. A., and P. C. L. Thorne. Lunge and Keane's Technical Methods of Chemical Analysis. Vol. I. Second edition. Pp. xx+704. London: Gurney and Jackson, 1924. Price 63s. net. (May 9, 1924.)

Kolthoff, J. M. Konduktometrische Titrationen. Pp. vi+94. Dresden and Leipzig: T. Steinkopff, 1923. Price 2s. 9d. (Jan. 4, 1924.)

Pregl, F. Quantitative Organic Microanalysis. Translated from the second revised and enlarged German edition by Dr. E. Fyleman. Pp. xv+190. London: J. and A. Churchill, 1924. Price 12s. 6d. (Oct. 3, 1924.)

Sadtler, S. S., E. C. Lathrop, and C. A. Mitchell. Allen's Commercial Organic Analysis, Part I. Pp. viii+796. London: J. and A. Churchill, 1924. Price 30s. (Aug. 29, 1924.)

Schimpf, H. W. Systematic Course of Qualitative Analysis. Fourth edition, revised by A. I. Cone. Pp. ix+194. New York: J. Wiley and Sons, Inc. London: Chapman and Hall, Ltd., 1924. Price 8s. 6d. (Oct. 24, 1924.)

Thurston, A. Pharmaceutical Analysis. Pp. 409. London: Chapman and Hall, Ltd. Price 21s. net. (May 16, 1924.)

CHEMICAL ENGINEERING

Brownlie, D. Mechanical Stoking. Pp. x+234. London: Sir Isaac Pitman and Sons, 1923. Price 5s. net. (May 2, 1924.)

Calcott, W. S., J. C. Whetzel, and H. F. Whittaker. Monograph on Corrosion Tests and Materials of Construction for Chemical Engineering Apparatus. Published by the American Institute of Chemical Engineers. Pp. vi+182. New York: D. Van Nostrand Co., 1923. Price $3. (May 16, 1924.)

Hausbrand, E. Drying by Means of Air and Steam. Third revised English edition. Pp. viii+77. London: Scott, Greenwood and Son, 1924. Price 6s. (Sept. 12, 1924.)

Paul, J. H. Boiler Chemistry and Feed Water Supplies. Second edition. Pp. ix+252. London: Longmans, Green and Co., 1923. Price 14s. net. (Jan. 25, 1924.)

Reichenberg, C. von. Einfache und Fraktionierte Destillation in Theorie und Praxis. Pp. xv+814. Leipzig: Schimmel and Co., 1923. Price: Paper, 17 g.m.; bound, 18 g.m. (Feb. 29, 1924.)

Swinden, N. Modern Theory and Practice of Pumping. Pp. 364. London: E. Benn, Ltd., 1924. Price 42s. (Sept. 5, 1924.)

Walker, W. H., W. K. Lewis, and W. H. McAdams. Principles of Chemical Engineering. First edition. Pp. ix+637. London: McGraw-Hill Publishing Co., Ltd., 1923. Price 25s. (Nov. 16, 1923.)

PHYSICS

Baly, E. C. C. Spectroscopy. Pp. xi+298. Third edition. Vol. I. London: Longmans, Green and Co., 1924. Price 14s. (Aug. 29, 1924.)

Houston, R. A. Light and Colour. Pp. xi+179. London: Longmans, Green and Co., 1923. Price 7s. 6d. (June 6, 1924.)

Houston, R. A. A Treatise on Light. Pp. xi+486. New edition, revised and enlarged. London: Longmans, Green and Co., 1924. Price 12s. 6d. (June 6, 1924.)

Rice, J. Relativity, a Systematic Treatment of Einstein's Theory. Pp. xiv+389. London: Longmans, Green and Co., 1923. Price 18s. (Jan. 18, 1924.)

GENERAL

Rickard, T. A. Technical Writing. Second edition, rewritten and enlarged. Pp. ix+337. New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1923. Price 10s. (Dec. 21, 1923.)

Comptes Rendus du Troisième Congrès de Chimie Industrielle (Paris, October 21–27, 1923). Pp. 1000. Paris: Société de Chimie Industrielle, 49, Rue des Mathurins. Subscription price, 50 fr. (May 16, 1924.)

Directory for the British Glass Industry, 1923. Published by the Society of Glass Technology, Sheffield. Price 7s. 6d. (Feb. 22, 1924.)

Journal of Scientific Instruments. Vol. I, No. 1. October, 1923. Pp. 32. London: The Institute of Physics. Price 2s. 6d. (Nov. 16, 1923.)

Kelly's Directory of Merchants, Manufacturers and Shippers of the World, 1924. Thirty-eighth edition. Vol. I, pp. ccci+2522. Vol. II, pp. cxvii+2458. London: Kelly's Directories, Ltd., 186, Strand, W.C. 2. Price 64s. (Aug. 22, 1924.)

Photography as a Scientific Implement. A Collective Work by various authors. Pp. viii+549. London: Blackie and Son, Ltd., 1923. Price 30s. (April 25, 1924.)

Second Year Book of the Institution of the Rubber Industry, 1923. Pp. xxiv+148. London: 10, Charing Cross Road, 1924. Price 5s. (March 21, 1924.)

Year Book of the American Association of Textile Chemists and Colorists. Pp. 165. New York, 1924. (Oct. 3, 1924.)

CHEMICAL INDUSTRY

Aitchison, L., and W. R. Barclay. Engineering Non-Ferrous Metals and Alloys. Pp. xx+300. London: Henry Frowde and Hodder and Stoughton, 1923. Price 24s. (Feb. 22, 1924.)

Allen, A. W. The Recovery of Nitrate from Chilean Caliche, containing a vocabulary of terms, an account of the Shanks system, with a criticism of its fundamental features, and a description of a new process. Pp. xvi+50. London: Charles Griffin and Co., 1921. Price 6s. (April, 25, 1924.)

Askinson, G. W. Perfumes and Cosmetics: Their Preparation and Manufacture. Pp. xiii+392. London: Crosby, Lockwood and Son, 1923. Price 30s. (Feb. 8, 1924.)

Baker, R. T., and H. G. Smith. Wood fibres of some Australian Timbers. Pp. 159. 64 plates. Sydney: Government Printer, 1924. Published by Authority of the Commonwealth Government. (Aug. 1, 1924.)

Bauer, E. P. Keramik. Fortschritte der Chem. Technologie in Einzeldarstellungen. Edited by Prof. B. Rassow. Part I. Pp. xi+143. Leipzig: T. Steinkopff, 1923. Price 4s. (Jan. 4, 1924.)

Bearn, J. G. The Chemistry of Paints, Pigments and Varnishes. Pp. x+277. London: E. Benn, Ltd., 1923. Price 30s. (Dec. 28, 1924.)

Bedford, C. W., and H. A. Winkelmann. Systematic Survey of Rubber Chemistry. Pp. 385. New York: The Chemical Catalog Co., Inc., 1923. Price $7.0. (Feb. 29, 1924.)

Billiter, J. Die Technische Chloralkali-Elektrolyse. Pp. viii+79. Dresden and Leipzig: Theodor Steinkopff, 1924. Price 2.50 g.m. (May 16, 1924.)

Blum, W., and G. B. Hogaboom. Principles of Electroplating and Electroforming (Electrotyping). Pp. xii+356. London: McGraw Hill Publishing Co., Ltd., 1924. Price 20s. (Aug. 1. 1924.)

BOLTON, E. R., and R. G. PELLY. Oils, Fats, Waxes and Resins. With a foreword by H.R.H. The Prince of Wales, K.G., and General Introductions by the Rt. Hon. Sir E. Geddes, G.C.B., and J. H. Batty. Pp. 275. London: E. Benn. Ltd., 1924. Price 21s. (May 30, 1924.)

DEAN, R. SCOTT. Theoretical Metallurgy. Pp. vii+246. London: Chapman and Hall, Ltd., 1924. Price 15s. (Aug. 29, 1924.)

DUNN, J. T. Pulverised and Colloidal Fuel. Pp. 197. London: Ernest Benn, Ltd., 1924. 25s. net. (July 18, 1924.)

DURVELLE, J. P. The Preparation of Perfumes and Cosmetics. Translated from the fourth French edition by E. J. Parry, B.Sc. Pp. viii+420. London: Scott, Greenwood and Son, 1923. Price 21s. (Feb. 8, 1924.)

EVANS, U. R. Metals and Metallic Compounds. Vol. I., Introduction, Metallography, Electro-Chemistry. Pp. xii+468. Price 21s. Vol. II., Metals of the "A" Groups. Pp. xi+396. Price 18s. Vol. III, The Transition Elements. Pp. xii+276. Price 14s. Vol. IV, Metals of the "B" Groups. Pp. xii+350. Price 18s. London: E. Arnold and Co., 1923. (Feb. 8, 1924.)

GOODRICH, W. F. Utilisation of Low-Grade and Waste Fuel. Pp. xix+368. London: E. Benn, Ltd., 1924. Price 42s. net. (July 18, 1924.)

GROGGINS, P. H. Aniline and its Derivatives. Pp. vii+256. London: Chapman and Hall, Ltd., 1924. Price 18s. net. (Oct. 3, 1924.)

HALSE, E. Cobalt Ores. Monograph of the Imperial Institute. Pp. 51. London: John Murray. Price 3s. 4d. (April 4, 1924.)

HARDEN, A. Alcoholic Fermentation. Third edition. Pp. 194. London: Longmans Green and Co., 1923. Price 6s. 6d. (Nov. 16, 1923.)

HARVEY, L. C. Pulverised Coal Systems in America. Fuel Research Board. Special Report No. 1. Third edition. Pp. 131. H.M. Stationery Office. Price 5s. (July 11, 1924.)

HAWLEY, L. F. Wood Distillation. American Chemical Society Monograph Series. Pp. 141. New York: The Chemical Catalog Co., Inc., 1923. Price $3. (Jan. 11, 1924.)

HECHT, H. Lehrbuch der Keramik. Pp. 336. Berlin and Vienna: Urban and Schwarzenberg, 1923. (Dec. 28, 1923.)

HUGHES, W. E. Modern Electro-Plating: A Guide Book for Platers, Works Chemists and Engineers. Pp. vii+160. London: H. Frowde and Hodder and Stoughton, 1923. Price 16s. (Aug. 22, 1924.)

KRAIS, P. Textilindustrie. Technische Fortschrittsberichte. Fortschritte der Chem. Technologie in einzeldarstellungen. Edited by Prof. B. Rassow. Part III. Pp. 156. Dresden and Leipzig: Theodor Steinkopff, 1924. Price, 4·50 g.m. (Feb. 8, 1924.)

LANDER, C. H., and R. F. MACKAY. Low Temperature Carbonisation. Pp. 277. London: E. Benn, Ltd., 1924. Price 35s. (July 4, 1924.)

LANGE, OTTO. Chemische-Technische Vorschriften. Ein Handbuch der Speziellen Chemischen Technologie Insbesondere fur Chemische Fabriken und Verwandte Technische Betriebe Enthaltend Vorschriften aus Allen Gebieten der Chemischen Technologie mit Umfassenden Literaturnachweisen. Vol. I. Metalle und Minerale. Pp. xxxvi+1011. Leipzig: Otto Spamer, 1923. Price, 32s., paper; 36s. bound. (Jan. 4, 1924.)

LANGE, OTTO. Chemisch-Technische Vorschriften. Vol. II. Fibres. Pulps and Varnishes. Pp. xix. 806. Third edition enlarged and completely revised. Leipzig: Otto Spamer, 1923. Price, paper, 37s.; bound 40s. (Jan. 4, 1924.)

LANGE, OTTO. Chemisch-Technische Vorschriften. Vol. III. Harze, Oele, Fette. Pp. xix+796. Third edition, enlarged and fully revised. Leipzig: Otto Spamer, 1923. Price, paper, 50 g.m. bound, 75 g.m. (April 11, 1924.)

LANGE, OTTO. Chemisch-Technische Vorschriften. Vol. IV. Dungemittel (Sprengstoffe), Futtermittel, Lebensmittel. Third edition completely revised and enlarged. Pp. 21-750. Leipzig: O. Spamer, 1924. Price, paper, 45 g.m. bound 50 g.m. (Sept. 12, 1924.)

LEDERLIN, P. Blanchiment. Teinture, Impression, Apprets. Edited by Prof. C. Matignon. Pp. 543. Paris: J. B. Bailliere, 1923. Price, paper, 45 frs.; bound, 55 frs. (Nov. 23, 1923.)

LESLIE, E. H. Motor Fuels, their Production and Technology. Pp. 681. New York: Chemical Catalog Co., Inc., 1923. Price $7. (Dec. 21, 1923.)

LUFF, B. D. W. The Chemistry of Rubber. Pp. 232. London: E. Benn Bros., Ltd., 1923. Price 25s. (Dec. 28, 1923.)

LUNGE, G. The Manufacture of Hydrochloric Acid and Salt Cake. The Manufacture of Acids and Alkalis. By Prof. G. Lunge and A. C. Cumming, O.B.E., D.Sc. Completely revised and rewritten. Vol. V. Pp xv+423. London: Gurney and Jackson, 1923. Price 31s. 6d. (Jan. 18, 1924.)

LUNGE, G. Manufacture of Nitric Acid and Nitrates. By Allin Cottrell, M.Sc. Vol VI. Manufacture of Acids and Alkalis. Completely revised and rewritten under the editorship of A. C. Cumming, O.B.E. Pp. xv+454. London: Gurney and Jackson, 1923. Price 36s. (Dec. 14, 1923.)

LUTTRINGER, A.-D. Aide-Memoire pour L'Industrie du Caoutchouc et des Matières Plastiques. Pp. 225. Paris: A.-D. Cillard, 1923. (May 9, 1924.)

McINTOSH, J. G. Industrial Alcohol. Second edition, revised and enlarged. By H. B. Stocks, F.I.C. Pp. xii+400. London: Scott, Greenwood and Son, 1923. Price 12s. 6d. net. (Feb. 15, 1924.)

MARTIN, G. The Modern Soap and Detergent Industry including Glycerol Manufacture. Vol. I. Theory and Practice of Soap Making. Pp. xii+384. London: Crosby Lockwood and Son, 1924. Price 36s. (May 9, 1924.)

MASSE, R., and A. BARIL. L'Industrie de Gaz: Vol. I. Distillation de la Houille. Pp. vii+292. Vol. II. Traitement des Produits et Sous-Produits. Pp. xvii+308. Paris: Masson et Cie, 1923. Price 20 frs. each volume. (Dec. 7, 1923.)

MATHESIUS, WALTHER. Die Physikalischen und Chemischen Grundlagen des Eisenhuttenwesens.. Second revised edition. Pp. xviii+483. Leipzig: O. Spamer, 1924. Price, bound, 30 g.m. paper, 27 g.m. (May 16, 1924.)

MITCHELL, H. V. Fuel Oils and Their Applications. Pp. xii+171. London: Sir I. Pitman and Sons, Ltd., 1924. Price 5s. (April 25, 1924.)

MATTHEWS, J. M. The Textile Fibers, Their Physical, Microscopical and Chemical Properties. Pp. xviii+1053. Fourth edition, revised and enlarged. New York: John Wiley and Sons, Inc., and London: Chapman and Hall, Ltd., 1924. Price 50s. (June 20, 1924.)

MORRELL, R. S. Varnishes and Their Components. Pp. xii+361. London: H. Frowde and Hodder and Stoughton, 1923. Price 25s. (Jan. 25, 1924.)

MOURRE, C. La Lavande Francaise, sa Culture, son Industrie, son Analyse. Pp. xxii+150. Paris: Gauthier-Villars et Cie, 1923. Price 10 frs. (Jan. 18, 1924.)

MYDDLETON, W. W., and T. H. BARRY. Fats: Natural and Synthetic. Pp. xi+182. London: E. Benn, Ltd., 1924. Price 25s. net. (May 9, 1924.)

Nickel Ores. Monograph issued by the Imperial Institute. Pp. 80. London: John Murray. Price 5s. (March 14, 1924.)

NICOL, E. W. L. Coke and Its Uses, in Relation to smoke Prevention and Fuel Economy. Pp. xii+132. London: E. Benn Bros., Ltd., 1923. Price 10s. 6d. (Dec. 21, 1923.)

PARKES, J. W. Concentration of Sulphuric Acid (Lunge-Cumming Series). Pp. xii+394. London: Gurney and Jackson, 1924. 31s. 6d. net. (July 4, 1924.)

PARRISH, P. The Design and Working of Ammonia Stills. Pp. xvii+283. London: E. Benn Bros., Ltd., 1924. Price 40s. (Sept. 19, 1924.)

PEARSON, H. P. Waterproofing Textile Fabrics. Pp. 112. New York: Chemical Catalog Co., Inc., 1924. Price $3.00. (Sept. 5, 1924.)

POLLATSCHEK, P. Die Fabrikation der Margarine. Monographien aus dem Gebiete der Fett-Chemie. Edited by Prof. K. H. Bauer. Vol. IV. Pp. 52. Stuttgart: Wissenschaftliche. Verlagsgesellschaft. m.b.H., 1923. Price, bound, 2.20 m.; paper, 1.80 m. (June 13, 1924.)

PORTER, H. C. Coal Carbonisation. American Chemical Society Monograph Series. Pp. 442. New York: The Chemical Catalog Co., Inc., 1924. Price $6. (Oct. 17, 1924.)

POUCHER, W. A. Perfumes and Synthetics with Special Reference to Synthetics. Pp. xi+462. London: Chapman and Hall, Ltd., 1923 Price 21s. (Feb. 8, 1924.)

QUINTUS, R. A. Cultivation of the Sugar-cane in Java. Pp. xi+164. London: Norman Rodger, 1923, Price 12s. (Dec. 14, 1923.)

Rubber Conference- Brussells, 1924. Pp. 218. London: Rubber Growers' Association. Price 5s. (Oct. 24, 1924.)

SEARLE, A. B. Sands and Crushed Rocks. Vol. I. Their Nature, Properties and Treatment. Pp. xiv+475. Vol II., Their Uses in Industry. Pp. viii+281. London: Henry Frowde and Hodder and Stoughton, 1923. Price 52s. 6d. (Mar. 14, 1924.)

SEARLE, A. B. The Chemistry and Physics of Clays and Other Ceramic Materials. Pp. xiii+695. London: Ernest Benn, Ltd., 1924. Price 55s. net. (March 14, 1924.)

SEELIGMANN, F., and EMIL ZIEKE. With the collaboration of W. Schlick and Dr. F. Zimmer. Handbuch der Lack- und Firnisindustrie. Third edition. Pp. 827. Edited by E. Zieke and Dr. H. Wolff, Berlin, 1923. (Nov. 16, 1923.)

SIMONS, T. Ore Dressing. Principles and Practice. First edition. Pp. xvii+292. London: McGraw-Hill Publishing Co., Ltd., 1924. Price 17s. 6d. (July 4, 1924.)

SINGER, FELIX. Die Keramik im Dienste von Industrie und Volkswirtschaft. Brunswick: Fr. Vieweg and Sohn, A.-G., 1924. Price 50s. (May 16, 1924.)

SMITH, S. The Action of the Beater. Translated by Major R. Marx, Pp. xi+212. London: The Technical Section of the Papermakers' Association of Great Britain and Ireland, 1923. Price 15s. (Sept. 19, 1924.)

SMYTHE, J. A. Lead. Its Occurrence in Nature, The Modes of Its Extraction, Its Properties and Uses, with some Account of Its Principal Compounds. Monographs on Industrial Chemistry. Edited by Sir Edward Thorpe, C.B., F.R.S. Pp. vi+343. London. Longmans, Green and Co., 1923. Price 16s. net. (Jan. 18, 1924.)

SPIELMANN, P. E. The Constituents of Coal Tar. Pp. xii+219. London: Longmans, Green and Co., 1924. Price 12s. 6d. (Nov. 14, 1924.)

STILLMAN, A. L. Briquetting. Pp. x+466. Easton, Pa. Chemical Publishing Co., 1923. Price $6.0. (July 11, 1924.)

STRACHE, H., and R. LANT. Kohlenchemie. Pp. xvi+599. Leipzig: Akademische Verlag G. m.b.H., 1924. Price, paper, 24 goldmarks bound, 26 g.m. (June 27. 1924.)

VEZES, M., and G. DUPONT Résines et Térébenthines; les Industries Dérivées. Encyclopedie de Chimie Industrielle. Pp. 656. Paris: J. B. Bailliere et Fils., 1924. Price, paper, 60 fr.; bound, 70 fr. (July 11, 1924.)

VOGEL, J. H., and ING. ARMIN SCHULZE. Carbid und Acetylen, als Ausgangsmaterial für Produkte der Chemischen Industrie. Pp. 130. Leipzig: Otto Spamer 1924. Price, paper, 5 g.m. bound, 6 g.m (Oct. 10, 1924.)

WARNES, A. R. Coal Tar Distillation and Working-Up of Tar Products. Third edition, rewritten and enlarged Pp. xv+511. London: Ernest Benn, Ltd., 1923. Price 45s. (Feb. 1, 1924.)

FORTHCOMING EVENTS

Dec. 1. OIL AND COLOUR CHEMISTS' ASSOCIATION, Joint Discussion with the SOCIETY OF CHEMICAL INDUSTRY, *London Section*, Chemical Society's Rooms, Burlington House, Piccadilly, London W. 1, "Protective Paints."

Dec. 1. INSTITUTION OF ELECTRICAL ENGINEERS, *Western Centre*, South Wales Institute of Engineers, Cardiff, at 6 p.m. "Modern Illumination," Demonstration by W. E. Bush.

Dec. 1. ROYAL SOCIETY OF ARTS, John Street, Adelphi, London, W.C. 2, at 8 p.m. Cantor Lecture, "Modern Colour Problems," by L. C. Martin. Also on December 8.

Dec. 1. UNIVERSITY OF BIRMINGHAM CHEMICAL SOCIETY. Chemical Lecture Theatre, Edgbaston, Birmingham, at 5.30 p.m. "The Bohr Theory of Atomic Structure," by R. E. Kellett.

Dec. 1. INSTITUTION OF THE RUBBER INDUSTRY, *London and District Section*, Engineers' Club, Coventry Street, London, W., at 8 p.m. "Research Work on the Plantation," by Major B. J. Eaton.

Dec. 2. INSTITUTE OF METALS, *Birmingham Section*, Chamber of Commerce, New Street. 7 p.m "Metal Spraying," by W. E. Ballard.

Dec. 2. INSTITUTE OF METALS, *North-East Coast Section*. Armstrong College, Newcastle-on-Tyne, at 7.30 p.m. "Aluminium, its Production and Uses," by G. B. Brook.

Dec. 2. WEST YORKSHIRE METALLURGICAL SOCIETY, George Hotel, Huddersfield, at 7.30 p.m. Discussion on "The Corrosion of Engineering Materials."

Dec. 2. IMPERIAL COLLEGE CHEMICAL SOCIETY. Main Chemistry Lecture Theatre, Royal College of Science, South Kensington, London, S.W. 7, at 5 p.m. "The Specific Heats of Gases," by Prof. J. R. Partington.

Dec. 2. INSTITUTION OF PETROLEUM TECHNOLOGISTS, at the House of the Royal Society of Arts, John Street, Adelphi, London, W.C. 2, at 5.30 p.m. "Fuel Oil Resources of the Future," by A. W. Nash and H. G. Shatwell. "The Somerset Oil Shales," by H. G. Shatwell, A. W. Nash, and J. Ivor Graham.

Dec. 3. INSTITUTE OF CHEMISTRY, *Leeds Area Section.* Annual Meeting will be held in the Great Northern Hotel, Leeds, at 7 p.m., instead of on November 26

Dec. 3. LITERARY AND PHILOSOPHICAL SOCIETY, *Chemical Section*, the Museum, New Walk, Leicester, at 8 p.m. "The Action of Light on the Photographic Plate," by Dr. T. Slater Price.

Dec. 3. ROYAL SOCIETY OF ARTS, John Street, Adelphi, London, W.C. 2, at 8 p.m. "The Teaching of Science in Secondary Schools," by Prof. C. A. Carus Wilson.

Dec. 3. SOCIETY OF CHEMICAL INDUSTRY, *Nottingham Section*, University College, Nottingham, at 7.30 p.m. A paper on Glass will be given by Prof. W. E. S. Turner.

Dec. 4. CHEMICAL SOCIETY, Burlington House, Piccadilly, W. 1, at 8 p.m. Ordinary Scientific Meeting. (1) "New Halogen Derivatives of Camphor. Part VI. β-Bromocamphor-α-sulphonic acid," by H. Burgess and T. M. Lowry. (2) "New Halogen Derivatives of Camphor. Part VII. The Constitution of the Reychler Series of Camphorsulphonic acids. Experiments on Chlorosulphoxides," by H. Burgess and T. M. Lowry.

Dec. 4. SOCIETY OF CHEMICAL INDUSTRY, *Bristol Section*, Chemical Department, The University, Woodland Road, Bristol, at 7.30 p.m. "Some International Aspects of the Dye Industry," by W. E. Fearnsides.

Dec. 4. SOCIETY OF DYERS AND COLOURISTS, *Bradford Junior Branch.* "Cotton Finishing," by E. Pearson.

Dec. 4. SOCIETY OF DYERS AND COLOURISTS, *West Riding Section.* "The Moth Proofing of Textiles and other Wearing Apparel," by C. O. Clark.

Dec. 4. INSTITUTE OF METALS, *Sheffield Section*, The University, St. George's Square, Sheffield, at 7.30 p.m. "Electro-Plating." Discussion to be opened by A. Jefferson. (Conjoint Meeting with the Silver Trades Society.)

Dec. 4. INSTITUTE OF CHEMISTRY, *Huddersfield Section.* "The Pioneers of Chemical Industry in Huddersfield," by Dr. L. Gordon Paul.

Dec. 5. SOCIETY OF CHEMICAL INDUSTRY, *Manchester Section*, Textile Institute, 16, St. Mary's Parsonage, Manchester, at 7 p.m. "Peptisation," by A. V. Slater.

Dec. 5. SOCIETY OF CHEMICAL INDUSTRY, *Liverpool Section*, Muspratt Lecture Theatre, The University, Liverpool, at 6 p.m. "Liquid Hydrocarbons obtained in the Compression of Oil Gas," by P. Lewis-Dale.

Dec. 5. INSTITUTION OF MECHANICAL ENGINEERS, Storey's Gate, London, S.W. 1, at 6 p.m. (1) "The Effect of Low and High Temperatures on Materials," by Prof. F. C. Lea, and (2) "The Elastic Limit in Tension, its Influence on the Breakdown by Fatigue," by J. M. Lessells.

Dec. 5. UNIVERSITY OF LONDON, King's College, *Faculty of Science*, Strand, London, W.C. 2, at 5.30 p.m. "The Historical Development of the Measurement of Stress in Materials Subjected to Load," by Prof. E. G. Coker.

Alteration.—The January meeting of the Manchester Section of the Society of Chemical Industry which had been arranged for January 2 is now arranged for January 9. In this meeting it is hoped that in addition to the paper by Messrs. Simpkin and Sinnatt, the Section will have the honour of welcoming and hearing a paper by Prof. Hugh S. Taylor of Princeton University, U.S.A., the title of his address to be "The Properties of a Catalytic Surface."

SOCIETY OF CHEMICAL INDUSTRY

MEETING OF COUNCIL

The monthly meeting of Council was held on November 14, the President (Mr. W. J. U. Woolcock, C.B.E.) in the Chair.

It was agreed to send an Address of Congratulation to the University of Leeds on the occasion of the celebration of its Coming of Age in December.

An invitation was received from the Committee of the London Section to hold the Annual General Meeting of the Society in London in 1926, and it was unanimously resolved to recommend to the Annual General Meeting in 1925 that this invitation be accepted.

The Society's representatives on Outside Bodies were re-elected for the year 1924–25 as follows :—

Federal Council for Pure and Applied Chemistry :—Mr. F. H. Carr, Dr. S. Miall, and Mr. W. J. U. Woolcock.

National Physical Laboratory (*General Board*) :—Sir Wm. J. Pope and Prof. J. W. Hinchley.

British Engineering Standards Association :—Aircraft Sub-Committee on Chemicals : Prof. W. A. Bone. Sub-Committee on Textiles : Mr. C. F. Cross. Sub-Committee on Dopes : Dr. J. N. Goldsmith. Sectional Committee of Chemical Engineering : Mr. C. S. Garland, Capt. C. J. Goodwin, Dr. W. R. Ormandy, and Mr. J. A. Reavell.

Imperial Mineral Resources Bureau :—Lead, Silver, Zinc, and Cadmium Sub-Committee : Mr. H. M. Ridge. Aluminium, Magnesium, Potassium, and Sodium Sub-Committee : Dr. R. Seligman. Minor Metals Sub-Committee : Mr. W. G. Wagner. Publication and Libraries Sub-Committee : Mr. W. J. A. Butterfield. Abstracts Sub-Committee : Prof. H. Louis and Mr. T. F. Burton. Chemical Industries Sub-Committee : Mr. C. S. Garland.

British Empire Sugar Research Association :—Prof. A. R. Ling and Mr. J. W. Macdonald.

Joint Committee for the Standardisation of Scientific Glassware :—Mr. F. H. Carr, Dr. R. T. Colgate, and Dr. Bernard Dyer.

Governing Board of Imperial College of Science and Technology :—Sir William Pearce.

Reference was made to the recent death of Mr. J. T. Wood, of Nottingham, an old member of the Society, a past Chairman of the Nottingham Section, and a contributor of valuable papers to the *Journal*. It was unanimously resolved to send a letter of sympathy to Mrs. Wood.

Reports of various Committees were submitted, and 28 new members were elected :—Home, 23 ; Overseas, 5.

The next meeting of Council will be held on Friday, December 12, 1924, at 2.30 p.m.

SUSPENSION OF ENTRANCE FEE

As an inducement to Chemists to become members, the Council has resolved that no entrance fee shall be paid by members joining the Society in 1925.

A form of application for membership was inserted at the end of this Section in the issue of the Journal for October 17, and it is hoped that it may be used to introduce a new member for next year.

BACK NUMBERS OF JOURNAL

The General Secretary will be glad to hear from Members or Subscribers who have copies of the *Journal* for January 4, June 13 and 27, July 4 and 25, September 19, or October 3 and 17, 1924, that they are willing to dispose of to the Society.

DEATHS

Fergusson, Donald M. (elected 1902), of 285, Fifty-first Avenue East, Vancouver, B.C., Canada, Analytical Chemist. In April, 1924.

Hellon, Dr. Robert (elected 1885), of 40, New Lowther Street, Whitehaven, Analytical Chemist. On Nov. 9, 1924.

Wood, Joseph T. (elected 1887), of 62, Park Road, Nottingham, Tanner. On Nov. 9, 1924.

LIVERPOOL SECTION

The second meeting was held on November 21, Mr. Edwin Thompson in the chair. In opening the proceedings, the chairman congratulated Dr. G. C. Clayton on his re-election to Parliament and also welcomed Prof. E. C. C. Baly on his return from his lecture tour in America.

Mr. J. L. F. Vogel, who read a paper entitled, "Notes on Alloy Metals used in Alloy Steels," said he wished to draw the attention of chemists to the wide field covered by the metallurgy of alloy steels and to the part played by chemistry in their production. He emphasised the very large extent to which alloy steels were now employed and showed how the intense concentration on the production of munitions during the war revealed the important part played by these steels and by the rarer metals employed in their manufacture. The first point to be remembered was that manufacturers and consumers were interested solely in the physical properties of steel; for them chemical analysis was merely a means of ensuring uniformity in production and freedom from deleterious impurities.

Accepted views on the structure of alloy steels were explained and the physical characteristics of the different alloy metals and deleterious impurities were tabulated for comparison. The extent to which useful information could be deduced from this table was discussed and each metal was briefly considered with reference to its effect on steel, its production from the ores and the sources of supply. The problem facing makers of ferro-alloys and alloy metals for steel was that the products they supplied must contain the desired metals within comparatively narrow limits and that they must be very free from any deleterious or even doubtful impurities, and they had to realise that their products would be judged more by their physical properties than by their composition. Broadly speaking, ferro-alloys such as ferro-tungsten, ferro-chrome and ferro-molybdenum, which were reduced directly from the ores by electric furnace or by thermit processes, called for the purest raw materials, since the possibility of eliminating impurities in the course of manufacture was very limited. The pure metals such as nickel, cobalt, tungsten, or chromium, could be produced from considerably less pure raw materials since the impurities could be eliminated in processes of manufacture. Alloy steels complying with a specification as to physical properties could sometimes be obtained by several different mixtures and the cost of raw materials was, therefore, an important consideration. Finally, attention was drawn to the need for improved quick methods of assay for mixtures and alloys of the various metals, and for improved processes for commercial production of the metals and ferro-alloys.

CHEMICAL SOCIETY

An ordinary scientific meeting was held on Thursday, November 20, the President, Prof. W. P. Wynne, occupying the Chair. Fellows were invited to attend, on December 9, at 4.30 p.m., a meeting of the Faraday Society: a group of papers on "Base Exchange in Soils" would be read. It was also announced that an award of the Harrison Memorial Prize would shortly be considered, and that applications, nominations or information should reach the President of the Chemical Society not later than December 1. Applications for the Annual Reports for 1924 (Fellows' price, 5s. 6d.) should also be received as soon as possible.

The first two papers were read by Dr. F. Challenger:—

The sulphur compounds of Kimmeridge shale oil. Part I. [With J. R. A. Jinks and J. Haslam.]

The authors find that on removal of bases, phenols, and traces of ketones from that portion of the oil which is volatile in steam, and subsequent distillation under reduced pressure, a fraction b.p. 80–100° is obtained. From this fraction 2-methylthiophen identified as mercury 2-methylthienyl chloride and bromide was obtained. Also tribromo-2-methylthiophen, b.p. 86–87° was obtained from the regenerated oil. The same fraction also contains toluene. The highest fractions of the oil are semi-solid, and on treatment with alcohol and ether, yield a sulphur-free wax-like solid, b.p. 62–63°.

The interaction of thiocyanogen and of hydrogen sulphide with unsaturated compounds. Part II. [With T. H. Bott.]

The product obtained from thiocyanogen and styryl methyl ketone (*T.*, 1923, **123**, 1055) has a composition PhCH:C(SCN)·COMe. It is probable that thiocyanogen forms an unstable dithiocyano-additive product with styryl methyl ketone, which loses a molecule of thiocyanic acid. Distyryl ketone gives a compound of analogous composition containing 2 thiocyano groups. Carvone also forms a mono-thiocyano-derivative. When styryl methyl ketone reacts with hydrogen sulphide, duplobenzylidene-acetone sulphide is obtained, for which Fromm has suggested the structure

$$\begin{array}{l} CH_3C(OH)\text{——}CH{:}CHPh \\ \quad\quad\;\; \rangle S \\ CH_3C(OH)\text{——}CH{:}CHPh \end{array}$$

the corresponding disulphide and the additive products from hydrogen sulphide and styryl phenyl

ketone being formulated similarly. On general considerations, and from analogy with carvone and carvotanacetone hydrosulphides, the structure

$$\begin{array}{c} CH_3.COCH_2.CHPh \\ | \\ S \\ | \\ CH_3.CO.CH_2.CHPh \end{array}$$

would appear more probable. The authors find that duplobenzylideneacetone sulphide is stable towards bromine in chloroform. With the disulphide the reaction is complicated, but indicates a saturated structure.

Prof. C. S. Gibson communicated :—

A new method for the preparation of 9-alkylcarbazoles. [With H. Burton.]

N-Methyl- (or ethyl) anthranilic acid condensed with *o*-bromonitrobenzene in the presence of potassium carbonate and copper powder yields 2′-nitro-*N*-methyl-(or ethyl)-diphenylamine-6-carboxylic acids. These acids on reduction with ferrous sulphate and ammonia are converted into the corresponding amino-acids which are easily characterised by well-defined acetyl-derivatives. The amino-acids, on being heated above their melting points lose a molecule of water, and give lactams (compare Clemo, Perkin, and Robinson, *J.*, 1924, **125**, 1779). The corresponding acetyl-derivative, under similar conditions, gives rise to the same lactam. 2′-Nitro-N-methyldiphenylamine-6-carboxylic acid gives a small yield of 9-nitro-N-methylacridone when it is heated with 95% sulphuric acid. The amino-acids, on diazotisation and treatment with sodium hydroxide solution form the corresponding 9-alkylcarbazole.

Prof. R. Robinson said it was significant that the carboxyl group should in the reaction described be so very easily displaced under the influence of a positively charged diazonium complex. It had long been realised that in aromatic substitution the entering group is positive and that displacement of a carboxyl group is analogous to substitution. The case under discussion was an excellent example of the combination of these hypotheses.

Dr. N. V. Sidgwick discussed :—

The behaviour of the simple halides with water.

The four results of treating the simple halides with water can be explained if we assume (A) that that water can form co-ordinate linkings either through its hydrogen or its oxygen, (B) that the maximum covalency of an element is 4 from Li to F, 6 from Na to Br, and 8 for the heavier elements.

(1) Ionisation will be promoted by hydration of the ion, through the negative effect of the co-ordinate linking; thus with a covalency of 4 we get Li^+ and Be^{++}: with 6, Na^+, Mg^{++}, and Al^{+++}: quadrivalent cations only appear when a covalency of 8 is reached (Sn^{++++}).

(2) If the element can take up two more electrons, it will join to the O of the water; the H will react with the Cl, giving hydrolysis to the hydroxide and HCl (BCl_3, $SiCl_4$, PCl_3, PF_6, IF_5, MoF_6, TeF_6, WF_6, WCl_6, UF_6).

(3) If it is exerting its full covalency already, it cannot combine with water at all, and will not react: CCl_4, SF_6, SeF_6.

(4) In NCl_3 and OCl_2 the covalency is below the maximum, but the octet is full and cannot expand; hence it will share a pair of its own electrons with the hydrogen of the water, giving $HOH \rightarrow NCl_3$. This will then lose HOCl, forming NH_3.

Prof. R. Robinson briefly referred to the anomaly of carbon tetraiodide, as also did the author, with whose fruitful ideas he was in general agreement.

Prof. H. Bassett pointed out that whether addition of water caused ionisation or hydrolysis seemed to depend on the number of added water molecules being large in comparison with that of the halogen atoms, or vice versa; actually, both ionisation and hydrolysis occurred together.

Prof. T. M. Lowry referred to a statement made, he believed, by Ciamician in 1891, that " water adds on in two different ways: to metallic atoms with oxygen inside, and otherwise with hydrogen inside."

Prof. R. Robinson then briefly described the syntheses dealt with in the following three papers :—

Experiments on the synthesis of certain higher aliphatic compounds. Part I. A synthesis of lactarinic acid and of oleic acid. [With (Mrs.) G. M. Robinson.]

A method of preparation of long-chain keto-acids has been devised. An ethyl alkylacetoacetate is converted into its sodium derivative and condensed with the ester chloride of a dibasic acid. The product is submitted to hydrolysis in stages. Starting with *n*-undecyl iodide and adipic acid, lactarinic acid, $CH_3{\cdot}[CH_2]_{11}{\cdot}CO{\cdot}[CH_2]_4{\cdot}CO_2H$, was obtained whilst *v*-ketostearic acid was prepared from *n*-heptyl iodide and sebacic acid. The conversion of *v*-ketostearic acid into oleic acid has already been carried out. The communication also contains an account of the reduction of stearolic acid to pure oleic acid and of the synthesis of γ-ketopalmitic acid, $CH_3{\cdot}[CH_2]_{11}{\cdot}CO{\cdot}[CH_2]_2{\cdot}CO_2H$.

A synthesis of pyrylium salts of anthocyanidin type. Part V. The synthesis of cyanidin chloride and of delphinidin chloride. [With D. D. Pratt.]

The methods whereby the authors synthesised pelargonidin (Part III) have been applied to the cases of cyanidin and delphinidin which are mono- and dihydroxy derivatives of pelargonidin respectively. ω-Methoxyacetoveratrone and ω-3:4:5-tetramethoxyacetophenone were required for these syntheses and obtained by a method exemplified in the case of the former. Veratroyl chloride and ethyl sodio-α-γ-dimethoxyacetoacetate react in ethereal solution to a product which yields pure ω-methoxyacetoveratrone on careful hydrolysis with dilute aqueous potassium hydroxide. It condenses with 2-hydroxy-4:6-dimethoxybenzaldehyde in presence of hydrogen chloride in ethereal solution with formation of the pentamethyl ether of cyanidin chloride and this is changed by boiling hydriodic acid and phenol into

cyanidin iodide. By double decomposition with silver chloride the chloride was produced and proved to be identical with the substance of natural origin. The synthesis of delphinidin was carried out in a similar manner.

A synthesis of myricetin and of a galangin monomethyl ether occurring in galanga root. [With J. Kalff.]

THE action of benzoic anhydride and sodium benzoate on ω-methoxychloracetophenone at 180° leads to a product which yields Testoni's *galangin monomethyl ether* on hydrolysis. Substituting trimethylgallic acid derivatives for those of benzoic acid, myricetin tetramethyl ether is obtained and this yields myricetin on demethylation.

CORRESPONDENCE

THE CHEMICAL SOCIETY

Sir,—Among the suggestions made by Prof. T. S. Patterson, in your issue of November 21, 1924, by way of overcoming some of the difficulties which now beset the Chemical Society, there is one to which I, in common with many others, would take strong exception—namely, that of abolishing the summaries and conclusions which I think it is most desirable to cultivate at the end of communications relative to chemical work.

Chemical literature is so profuse nowadays that it is impossible, no matter to what extent one may specialise, to study all papers in detail, and, on the other hand, it appears to me that much of the detail could be, with advantage, omitted or condensed, and more care be taken to draw and express conclusions.

There is, however, only one radical cure for the troubles which are encountered by the Chemical and allied societies—namely, the creation of one real Institute of Chemistry, as first suggested by the writer in the "Chemical Trade Journal" (of April 8, 1916), a subject which is now engaging, as I understand, considerable attention at other hands, under the term "Chemistry House."

One comprehensive journal of transactions (planned sectionally) and one set of abstracts of papers from sources outside Chemistry House, are the great desirabilities.—Yours faithfully, C. T. KINGZETT

November 24, 1924.

PERSONAL AND OTHER ITEMS

H.R.H. the Prince of Wales has consented to open the new Chemistry Department of the University of Edinburgh on December 3.

The Council of the University of Birmingham has made the following appointments for the session 1924–25: Mr. A. R. Bowen to be Research Worker in the Department of Oil Mining, Mr. S. H. Edgar to be teaching scholar in the Department of Chemistry, Mr. A. W. Paynton to be Student Demonstrator in the Department of Bio-chemistry of fermentation.

Mr. J. W. Saville, who has been employed on the commercial staff of Messrs. Brotherton and Co., Ltd., for more than forty years, has been appointed a Justice of the Peace for Wakefield.

The Scholarship of the Institution of Petroleum Technologists, granted to a student member of the Institution who is completing the petroleum technology course at Birmingham University, has been awarded to Mr. Geoffrey Cotton.

Captain Oliver Lyttelton, D.S.O., has been elected to a seat on the board of the British Metal Corporation, Ltd., and has been appointed a joint managing director.

MM. Painlevé, Gaston Menier, E. Borel, Dal Piaz, Dervillé, Albin Haller, Picard, Rateau Koenigs and others have been appointed for four years' membership of the Council of the Administration of the National Conservatoire of Arts et Métiers at Paris.

Mr. H. T. Cranfield, senior lecturer in agricultural chemistry and head of the chemical department of the Midland Agricultural and Dairy College, has been appointed adviser in agricultural chemistry for the Midland counties served by the College.

Isotopes of Cadmium; Tellurium and Bismuth

In a letter to *Nature*, dated November 4, Dr. F. W. Aston writes that he has now succeeded in obtaining and analysing the mass-rays of cadmium, tellurium and bismuth. By the use of an anode containing cadmium fluoride, rays were obtained which, though feeble, gave satisfactory results with long exposures and the most highly sensitised schumannised plates. Cadmium is a very complex element, having six isotopes: 110 (c), 111 (e), 112 (b), 113 (d), 114 (a), 116 (f.). The last is isobaric with the lightest isotope of tin. The intensities of the lines are in the order of the letters and agree reasonably with the chemical atomic weight 112·41. The most striking characteristic of the group is its remarkable similarity to that of tin. If we except the heaviest isotope of tin (124), which does not seem to have its counterpart in cadmium, the intensity relations between the isotopes of the two elements appear almost identical. This is a most suggestive fact and may have a deep significance in connexion with the relative stability of the nuclei of isotopes. The plates are not very favourable for accurate determinations of masses, but these seem integral with that of iodine.

The line of the latter element was extremely faint in these experiments, so it was considered a favourable opportunity to make another attempt on tellurium, which had defied all attacks during the earlier discharge tube work. A little pure metallic tellurium was ground into the anode mixture and success was at once obtained. Tellurium gives three lines of mass numbers—126, 128, 130. The intensities of the two latter appear about equal and double that of the first. This result was repeated with an anode containing tellurium and lithium fluoride, and there is no reason to doubt that these are all genuine isotopes. Comparison with other lines on the plates suggests that their masses may be less than whole numbers by one or two parts in a thousand, but it seems probable that the mean atomic weight is actually greater than 128, whereas all the later chemical determinations are less than that figure, the accepted value being 127·5. The element tellurium is unique among those so far

analysed, as it seems probable that all its mass-numbers form members of isobaric pairs. These are shared by xenon, the element of next higher even atomic number.

The boiling-point of tellurium is not very different from that of bismuth, so that it seemed possible that the latter might yield to the same treatment. This hope was realised with an anode containing metallic bismuth, and a single line appeared in the expected position—209. This line is very faint, and owing to the great mass lies in an unfavourable part of the plate, but there seems no reason to doubt that bismuth is a simple element of mass number 209, as recent determinations of its atomic weight suggest.

The Van't Hoff Celebration

This year half a century has passed since van 't Hoff (in September, 1874) and Le Bel (in November, 1874) published their celebrated memoirs which form the foundation of "Chemistry in Space," or Stereo-chemistry. In honour of this event, which is of such outstanding importance for the development of chemistry, a commemorative celebration has been held in the Aula of the University of Amsterdam, under the auspices of the Dutch Chemical Society and of the Dutch Society of Chemical Industry, at which Prof. Dr. Ernst Cohen, of Utrecht, and Prof. Dr. Paul Walden, of Rostock, spoke. At the request of the firm of J. A. A. Gerritsen, of Zeist (Holland), the well-known Dutch medallist, J. C. Wienecke, has prepared gratuitously a plaque (57 by 45 mm.) bearing the portrait of van 't Hoff at the age of 22, the age at which he published his theory. The plaque can be obtained from the above firm at the price of 2.50 Gulden, in bronze, or 12 Gulden in silver, or about 4s. 4d. and 2s., respectively.

British Standard Specifications for Fuel Oils

These Specifications for fuel for heavy-oil engines ("Petroleum and Shale Oils," No. 209, 1924) are some of the first fruits of the Sectional Committee on petroleum products of the British Engineering Standards Association. Specifications are given for four grades of fuel oil, one being a gas oil and the rest non-distillate oils; all classes of heavy-oil engines thus being catered for. Users of heavy-oil engines should satisfy themselves, by test or otherwise, which of the four grades of oil specified can most satisfactorily be utilised in any given engine, and the corresponding specification should then be adopted. It is of interest to note that no mention of specific gravity is made, as the conclusion has been reached that it is quite unnecessary to specify the specific gravity of a fuel oil provided the viscosity characteristics are clearly defined. Further, the sulphur content is not specified. Every effort was made to obtain evidence to prove that the harmful effects attributed to oils in certain cases were due to the sulphur in the oil. Pending the production of such evidence it has been decided that for fuel oils used in heavy-oil engines but not under boilers, a test for sulphur unnecessarily increases the cost of the oil. The specifications will be revised, if necessary, in twelve months' time. The methods of testing the oil given in these specifications are those adopted by the Institution of Petroleum Technologists, and are described in detail. Copies may be obtained from the B.E.S.A. Publications Department, 28, Victoria Street, London, S.W. 1, price 1s. 2d., post free.

Wood-charcoal Gas Producers

The French Commission de Carbonisation is obtaining satisfactory results in its work on the improvement of portable charcoal-gas producers. At present the French production of wood charcoal is only 150,000 metric tons, but this quantity could be increased, without harming the forests, to 1,000,000 t. The Commission proposes, whilst encouraging the development of the production of charcoal, to have recourse to carbonisation in the forests, and will therefore hold a competition in the following spring for transportable plant for carbonisation. Tests are under way at Sevran Livry, on different types of gas producers, the tests taking account of the analysis of the fuels, their resistance to shock, the analysis of the gas produced and the ash obtained, the measurement of the power produced, and other working characteristics.

COMPANY NEWS

BRIMSDOWN LEAD CO.

According to the *Investor's Chronicle* we understand that an important further step is about to be taken towards completely consolidating the white lead interests in this country. The Associated Lead Manufacturers' combine now embraces Cookson and Co., Ltd., the largest business of the kind in Great Britain; Locke, Lancaster and Johnsons, Ltd.; and Rowe Brothers. The capital is £740,000 in 6 per cent preference shares and £1,000,000 in ordinary shares. Arrangements are now being made to acquire the Brimsdown lead business, and thus strengthen the combine. The acquisition will be on a share basis, Brimsdown preference shareholders receiving 15s. per share (66 per cent. in preference and 33 per cent. in ordinary shares of the combine), and Brimsdown ordinary 3s. 6d., all in ordinary shares. It is expected that the directors of the Brimsdown Lead Co. will send details of the offer of the Associated Lead Manufacturers to the shareholders in the course of a few days and recommend its acceptance. The transfer books of the Brimsdown Co. are closed for a few days to facilitate payment of a dividend on the preference shares.

ILFORD, LTD.

The net profit for the year to October 31, 1924, amounted to £56,747, compared with £46,686 last year. The sum of £8802 was brought forward and there is a total of £65,549 for appropriation. £11,400 is for preference dividend, £5000 has been written off goodwill (against £10,000), and £10,000 has been transferred to reserve (against nil). The dividend, after being 8 per cent. for the last five years, has been raised to 10 per cent. on the ordinary shares, and the sum of £8149 is to be carried forward.

BRITISH SULPHATE OF AMMONIA FEDERATION, LTD.

The fourth annual general meeting was held on October 20, Mr. D. Milne Watson (President of the Gas, Light and Coke Co.) presiding. The outstanding features in the sulphate of ammonia market in the year under review was a large increase in consumption and a considerable fall in price. Organisations, similar to this federation, had been formed in France, Belgium, Holland, Germany, Italy, Japan and Australia, the chief objects being to establish and maintain a reasonable price for this product calculated to induce consumption on the largest scale, and also for the combination of propaganda effort. During the last eighteen months there had been an increase in consumption of nearly 200,000 t. of sulphate of ammonia on a total world production of, roughly, 2,500,000 t., and this increase was secured at a comparatively small sacrifice in price. An appeal was made to non-members, whose total production amounted to less than 10 per cent. of the output in this country, to join the federation and so enable it to increase its propaganda activities, and to carry through a reasonable and logical programme, beneficial both to consumer and producer.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech. ..	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder	£47 per ton.
Acid Hydrochloric ..	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder ..	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime ..	£7 10s. per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Copper Sulphate	£25 per ton.
Methylated Spirit 64 o.p.—	
Industrial	2s. 7d.—2s. 11d. per gallon, according to quantity.
Mineralised	3s. 8d.—4s. per gallon, according to quantity.
Nickel Sulphate .. .. **Nickel Ammon. Sulphate**	£38 per ton d/d. Normal business.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate ..	5¾d. per lb.
Potass. Chlorate	3d.—4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£3 10s. per ton d/d.
Soda Caustic, solid ..	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton, carr. paid.
Sod. Bichromate	4½d. per lb.
Sod. Bisulphite Powder 60/62%	£17—£18 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst. ..	£9 per ton d/d.
Sod Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	6½d.—1s. 2d. per lb., according to quality.

Antimony sulphide—	
Crimson	1s. 4d.—1s. 6d. per lb., according to quality.
Arsenic, Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide	£30—£33 per ton, according to quantity.
Carbon Black	7d.—7½d. per lb. ex wharf.
Carbon Tetrachloride	£60—£65 per ton, according to quantity, drums extra.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes White and Dark	5d.—9½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	£48 per ton, barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£16 5s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Precip. B.P.	£50—£65 per ton, according to quantity.
Sulphur Chloride	4d. per lb., carboys extra.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep	5s. 1d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£11 10s. per ton, and upwards.
Grey	£14 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 5s.—£9 per ton, according to grade and locality. Demand quiet but price steady.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 9d. per gall. Unrefined.
Wood Naphtha—	
Miscible	4s. 9d. per gall. 60% O.P.
Solvent	5s. per gall. 40% O.P. Firmer.
Wood Tar	£4—£5 per ton. Very quiet.
Brown Sugar of Lead	£41 per ton. Steady market.

TAR PRODUCTS

Acid Carbolic—	
Crystals	6¼d. per lb. Quiet.
Crude 60's	1s. 8d.—1s. 10d. per gall. Market better.
Acid Cresylic, 97/99	2s. per gall. Fair business.
Pale 95%	1s. 8d.—1s. 11d. per gall. Not much business.
Dark	1s. 7d.—1s. 9d. per gall. Market dull.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	6½d.—7½d. per gall. Small demand
Unstrained	6d.—6½d. per gall.
Benzole—	
Crude 65's	7½d.—9d. per gall. ex works in tank wagons.
Standard Motor	1s. 1½d.—1s. 3d. per gall. ex works in tank wagons.
Pure	1s. 5½d.—1s. 7d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5½d.—1s. 7d. per gall. More inquiry.
Toluole—Pure	1s. 7d.—1s. 9d. per gall. Small demand for home consumption.
Xylol—Coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	8d.—8½d. per gall. Little demand.
Middle Oil, Heavy Oil, Standard Specification	5½d.—6½d. per gall., according to quality and district. Market firmer. Steady demand.
Naphtha—	
Solvent 90/160	1s. 3d.—1s. 4d. per gall. Demand good. Higher prices probable.
Solvent 90/190	11½d.—1s. 1d. per gall. Demand maintained.
Naphthalene Crude—	
Cheaper in Yorkshire than Lancashire. Demand rather better.	
Drained Creosote Salts	£3—£5 per ton. Demand slightly better.
Whizzed or hot pressed	£6—£9 per ton. Demand very poor.
Naphthalene—	
Crystals and Flaked	£12—£15 per ton, according to district.
Pitch, medium soft	45s.—60s. per ton according to district. Plenty of inquiry. Prospects brighter.
Pyridine—90/160	18s. 6d.—19s. per gall. Market quiet.
Heavy	11s. 6d.—12s. per gall. Steady.

INTERMEDIATES AND DYES

Business in dyestuffs has been maintained but without further improvement.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 7d. per lb.
Acid H.	3s. 10d. per lb. 100% basis d/d.
Acid Naphthionic	2s. 2d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 1d. per lb. Improved demand.
Acid Sulphanilic	9d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	8d. per lb. naked at works.
Aniline Salts	8½d. per lb., naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	3s. 10d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 1d. per lb.
p-Chloraniline	3s. per lb. 100% basis.
p-Chlorphenol	4s. 3d. per lb. d/d.
o-Cresol 19/31° C.	4d.—4½d. per lb. Rather quiet.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	3s. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£85 per ton.
Diethylaniline	4s. 3d. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 2½d. per lb. d/d. Drums extra.
Dinitrobenzene	9d. per lb. naked at works.
Dinitrochlorbenzol	£84 per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine	2s. 10d. per lb. d/d.
G. Salt.	2s. 3d. per lb. 100% basis d/d.
Monochlorbenzol	£63 per ton.
a-Naphthol	2s. 4d. per lb. d/d.
β-Naphthol	1s. per lb. d/d.
a- Naphthylamine	1s. 3½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	4s. 2½d. per lb. d/d.
p-Nitraniline	2s. 2½d. per lb. d/d.

Nitrobenzene ..	.. 5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	.. 2s. 11d. per lb. 100% basis d/d.
Nitronaphthalene	.. 10d. per lb. d/d.
p-Nitrophenol ..	.. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	.. 4s. per lb. d/d.
p-Phenylene Diamine	.. 10s. per lb. 100% basis d/d.
R. Salt	.. 2s. 4d. per lb. 100% basis d/d.
Sodium Naphthionate	.. 2s. 2d. per lb. 100% basis d/d.
o-Toluidine ..	.. 10d. per lb. naked at works.
p-Toluidine ..	.. 2s. 10d. per lb. naked at works.
m-Toluylene Diamine	.. 4s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	.. £45 per ton, ex wharf London, in glass containers.
Acid, Acetyl Salicylic	.. 3s. 1d.—3s. 3d. per lb., according to quantity. Sales steady. Price firm.
Acid, Benzoic B.P.	.. 2s. 6d. per lb.
Acid Boric B.P. ..	.. Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric ..	.. 19s.—21s. per lb.
Acid, Citric ..	.. 1s. 4d. per lb., less 5% for ton lots. Market still weak.
Acid, Gallic ..	.. 2s. 11d. per lb. for pure crystal in cwt. lots.
Acid, Pyrogallic, Cryst.	.. 6s. 9d. per lb. Resublimed quality 8s. per lb. Market firm.
Acid Salicylic	.. 1s. 6d.—1s. 7d. per lb., according to quantity.
Acid, Tannic B.P.	.. 2s. 10d. per lb. Forward quotations higher spot value likely to increase.
Acid, Tartaric ..	.. 1s. per lb., less 5%.
Amidol	.. 9s. per lb. d/d.
Acetanilide ..	.. 1s. 10d.—2s. per lb. More enquiry.
Amidopyrin ..	.. 15s. per lb.
Ammon. Benzoate	.. 3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	.. 12s. 6d. per oz. for English make.
Barbitone	.. 13s. 9d. per lb. Slightly lower. Quiet steady demand.
Benzonaphthol ..	.. 5s. 3d. per lb. spot.
Bismuth Carbonate	.. 8s. 6d.—10s. 6d. per lb.
„ Citrate ..	.. 8s. 6d.—10s. 6d. „
„ Salicylate	.. 8s. 0d.—10s. 0d. „
„ Subnitrate	.. 7s. 9d.—9s. 7d. „ According to quantity. Prices again reduced owing to fall in the metal.
Borax B.P. ..	.. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	.. Very scarce and dear. Prices uncertain.
Ammonium ..	.. 2s. 1d. per lb.
Potassium ..	.. 1s. 11d. per lb.
Sodium	.. 2s. per lb.
Calcium Lactate ..	.. 1s. 7d.—2s. per lb., according to quantity. Fair demand and steady market.
Chloral Hydrate ..	.. 4s. per lb.
Chloroform ..	.. 2s. 6d. per lb. for cwt. lots.
Formaldehyde ..	.. £48—£49 per ton in barrels, ex wharf London. Supplies exceed demand.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free ..	.. 7s. per lb.
Iron	.. 8s. 9d. per lb.
Glycerophosphates—	
Magnesium ..	.. 9s. per lb.
Potassium, 50%	.. 3s. 6d. per lb.
Sodium, 50% ..	.. 2s. 6d. „
Guaiacol Carbonate	.. 9s. 6d. per lb.
Hexamine ..	.. 3s. per lb. for bold crystal. Powder slightly less.
Homatropine Hydrobromide	.. 25s.—30s. per oz.
Hydrastine hydrochlor	.. English make offered, 120s. per oz.
Hypophosphites—	
Calcium ..	.. 3s. 6d. per lb., for 28-lb. lots.
Potassium ..	.. 4s. 1d. per lb.
Sodium ..	.. 4s. „
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 3d. per lb. Price recently reduced.
Magnesium Carbonate—	
Light Commercial	.. £36 per ton net.
Light, pure ..	.. £46 per ton.
Magnesium Oxide—	
Light Commercial	.. £75 per ton, less 2½%.
Heavy Commercial	.. £25 per ton, less 2½%.
Heavy Pure ..	.. 2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	.. 57s. per lb. for December delivery. No spot deliveries available.
Synthetic ..	.. 26s.—35s. per lb., according to quantity. English make. Increasing demand.
Mercurials ..	.. Market very quiet.
Red oxide ..	.. 5s. 2d.—5s. 4d. per lb.
Corrosive sublimate	.. 3s. 5d.—3s. 7d. „
White precip. ..	.. 4s. 6d.—4s. 8d. „
Calomel ..	.. 3s. 10d.—4s. „
Methyl Salicylate	.. 1s. 9d.—2s. per lb.
Methyl Sulphonal	.. 22s. 6d. per lb. Slightly weaker.
Metol	.. 11s. per lb. British make.
Paraformaldehyde	.. 2s. 8d. per lb. for B.P. quality.
Paraldehyde ..	.. 1s. 2d.—1s. 6d. per lb. in free bottles and cases.
Phenacetin ..	.. 5s. 6d. per lb.
Phenazone ..	.. 6s. 10d. per lb.
Phenolphthalein ..	.. 5s. 6d. per lb. for cwt. lots. Supply exceeds demand.
Potass. Bitartrate— 99/100% (Cream of Tartar) ..	.. 84s. per cwt., less 2½% for ton lots.
Potass. Citrate ..	.. 1s. 10d.—2s. 2d. per lb.
Potass. Ferricyanide	.. 1s. 9d. per lb. Quiet.
Potass. Iodide ..	.. 16s. 8d.—17s. 5d. per lb., according to quantity. Steady market.
Potass. Metabisulphite	.. 7½d. per lb., 1-cwt. kegs included. F.o.r. London.
Potass. Permanganate	.. 7½d. per lb. spot. Forward prices higher.
Quinine Sulphate	.. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	.. 5s. 3d. per lb.
Saccharin ..	.. 63s. per lb., in 50-lb. lots.
Salol	.. 3s. 9d. per lb. for cwt. lots.
Silver Proteinate ..	.. 9s. per lb. for satisfactory product, light in colour.
Sod. Benzoate, B.P.	.. 2s. 6d. per lb. Supplies of good quality now available.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite— Photographic ..	.. £13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	.. 16s. per lb.

Sod. Potass. Tartrate (Rochelle Salt) ..	75s.—82s. 6d. per cwt., according to quantity. Quiet market.
Sod. Salicylate	Fair demand. Powder 2s. 1d.—2s. 3d. per lb. Crystal at 2s. 2d.—2s. 4d. per lb. Flake 2s. 6d. per lb. Good demand. Market firmer.
Sod. Sulphide—	
Pure recryst.	10d.—1s. 2d. per lb.
Sod. Sulphite, anhydrous	£27 10s. per ton, minimum 5-ton lots, increasing according to quantity, 1-cwt. kegs included.
Sulphonal	14s. 6d. per lb. Little demand.
Thymol	18s. per lb. Firmer market.

PERFUMERY CHEMICALS

Acetophenone	11s. 3d.	per lb.	
Aubepine	15s.	,,	Cheaper.
Amyl Acetate	3s.	,,	Cheaper.
Amyl Butyrate	6s. 6d.	,,	
Amyl Salicylate	3s. 3d.	,,	
Anethol (M.P. 21/22° C.)	4s. 6d.	,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 9d.	,,	
Benzyl Alcohol free from Chlorine	2s. 9d.	,,	
Benzaldehyde free from Chlorine	3s. 6d.	,,	
Benzyl Benzoate	3s. 6d.	,,	
Cinnamic Aldehyde—			
Natural	18s. 6d.	,,	Cheaper.
Coumarin	18s. 9d.	,,	
Citronellol	17s.	,,	
Citral	8s.	,,	
Ethyl Cinnamate ..	12s. 6d.	,,	
Ethyl Phthalate	3s.	,,	Cheaper.
Eugenol	10s. 6d.	,,	Dearer.
Geraniol (Palmarosa) ..	33s. 6d.	,,	
Geraniol	12s. 6d.—20s.	per lb.	Dearer.
Heliotropine	6s. 9d.	,,	
Iso Eugenol	16s.	,,	
Linalol ex Bois de Rose ..	26s.	,,	
Linalyl Acetate	26s.	,,	
Methyl Anthranilate ..	10s.	,,	Dearer.
Methyl Benzoate	5s.	,,	
Musk Ambrette	50s.	,,	
Musk Xylol	14s.	,,	Dearer.
Nerolin	4s. 6d.	,,	Cheaper.
Phenyl Ethyl Acetate ..	15s. 6d.	,,	Dearer.
Phenyl Ethyl Alcohol ..	16s.	,,	
Rhodinol	55s.	,,	
Safrol	1s. 10d.	,,	
Terpineol	2s. 4d.	,,	
Vanillin	25s. 6d.	,,	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.
Anise Oil	2s. 10d. per lb.
Bergamot Oil	16s. per lb.
Bourbon Geranium Oil ..	35s. per lb.
Camphor Oil	65s. per cwt.
Cananga Oil Java ..	11s. per lb.
Cassia Oil, 80/85% ..	9s. 9d. per lb.
Cinnamon Oil, Leaf ..	6¼d. per oz.
Citronella Oil—	
Java 85/90%	5s. 10½d. per lb.
Ceylon	3s. 8d. per lb.
Clove Oil	8s. 3d. per lb.
Eucalyptus Oil 70/75% ..	2s. 3d. per lb.
Lavender Oil—	
French 38/40% Esters	35s. per lb.
Lemon Oil	3s. 2d. per lb.
Lemongrass Oil	5s. per lb.
Orange Oil, Sweet ..	11s. per lb.
Otto of Rose Oil—	
Bulgarian	40s. per oz
Anatolian	18s. per oz.
Palma Rosa Oil	16s. 6d. per lb.
Peppermint Oil—	
Wayne County ..	35s. per lb. nominal.
Japanese	22s. 6d. per lb. nominal.
Petitgrain Oil	9s. 9d. per lb.
Sandal Wood Oil—	
Mysore	26s. 7d. per lb.
Australian	18s. 6d. per lb.

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before Jan. 19th, they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on Dec. 4th.

I.—Applications

Askania-Werke Akt.-Ges., and Wünsch. 26,805. *See* II.

Bendixen, McKechnie, and Reid. Extraction, solution, and mixture of soluble and insoluble substances. 26,909. Nov. 11.

British Drug Houses, Ltd. Apparatus for comparing colour of liquids. 27,006. Nov. 12.

Dunstan and Remfry. Purification of liquids. 27,132. Nov. 13.

Foster. Radiation pyrometers. 27,335. Nov. 15.

Granger and Mariller. Rectification of liquids. 27,055. Nov. 12. (Fr., 12.11.23.)

Johnson (Badische Anilin und Soda Fabrik). Carrying out reactions under pressure. 27,027. Nov. 12.

Randolph. Dryers for granular material. 26,780. Nov. 10. (U.S., 24.12.23.)

Salerni. Apparatus for removing dust from gases etc. 26,826. Nov. 10.

Salerni. Condensers. 26,836. Nov. 10.

I.—Complete Specifications Accepted

19,985 (1923). Eichengrun. Preventing the flammability of easily inflammable articles and extinguishing fire. (202,302.)

21,074 (1923). Schmidt. Drying or heating apparatus. (224,313.)

4281 (1924). Imray (Meister, Lucius, und Bruning). Process of expelling volatile substances by means of a stream of vapour. (224,431.)

4638 (1924). Soc. d'Exploit. des Procédés Hiloux. Dryer and pulveriser. (211,887.)

9980 (1924). British Thomson-Houston Co., Ltd. Apparatus for separating particles of foreign matter from liquid. (214,990.)

10,878 (1924). Portes. Mixing liquids of different temperatures and regulating the temperature of the mixed liquids. (216,849.)

II.—Applications

Aktiebolaget Separator-Nobel. Separating paraffins from liquid hydrocarbons. 27,242, 27,243. Nov. 14. (Sweden, 28.11.23.)

Askania-Werke Akt.-Ges., and Wünsch. Regulating withdrawal of gas from retorts or furnaces. 26,805. Nov. 10.

Brutzkus. Obtaining water-gas from liquid hydrocarbons. 26,786. Nov. 10.

Carlson and Gröndal. Production of oil etc. from shales etc. 27,130. Nov. 13. (Sweden, 17.11.23.)

Deutsche Glühfadenfabrik, and Schwarzkopf. Incandescent cathodes. 26,938. Nov. 11. (Ger., 21.5.24.)

Dunstan and Remfry. 27,132. *See* I.

Gérard. Gas-generators. 27,277. Nov. 14. (Fr., 12.12.23.)

Hertel. Distillation of carbonaceous material. 27,170. Nov. 13.

Johnson (Wood). Gas-producers. 27,238. Nov. 14.

O'Donnell. Fuel briquettes. 26,810. Nov. 10.

Potts (Algemeene Norit Maatschappij). Manufacture of decolorising carbon. 26,993. Nov. 12.

Potts (Algemeene Norit Maatschappij). Manufacture of active carbons. 26,992, 26,993. Nov. 12.

Rolland. Separation of combustible constituents from clinkers etc. 27,253. Nov. 14. (Ger., 12.4.24.)

Salerni. Distillation etc. of carbonaceous etc. materials. [illegible].284. Nov. 14.

Whitfield. Gasification of fuel in steam-boiler furnaces. [illegible].212. Nov. 14.

[illegible].—Complete Specification Accepted

1794 (1924). Stinnes-Riebeck Montan- und Oelwerke Akt.-Ges. Separating benzol or benzine from mixtures containing dilute alcohol. (210,094.)

III.—Complete Specifications Accepted

20,574 (1923). Chemical Engineering and Wilton's Patent Furnace Co., Ltd., and Shadbolt. Distillation of tar. (224,305.)

1794 (1924). Stinnes-Riebeck Montan- und Oelwerke Akt.-Ges. *See* II.

IV.—Applications

Barnard, Mercer, and Roth. Production of dyestuffs for cellulose esters. 27,317. Nov. 15.

Scottish Dyes, Ltd., Thomas, and Thomson. Manufacture of dyestuffs etc. 27,012. Nov. 12.

IV.—Complete Specification Accepted

26,725 (1923). British Dyestuffs Corporation, Ltd., Baddiley, and Tatum. Dyestuffs of the anthraquinone series. (224,363.)

V.—Applications

Arrizabalaga. Manufacture of waterproof fabrics. 27,247. Nov. 14.

Barnard, Mercer, and Roth. 27,317. *See* IV.

Barrett, Coward, and Tootall Broadhurst Lee Co., Ltd. Cellulosic material. 26,987. Nov. 12.

Holman and Leicester. Manufacture of paper. 27,163. Nov. 13.

Johnson (Badische Anilin- und Soda-Fabrik). Manufacture of coloured cellulose plastics etc. 27,028. Nov. 12.

Molinari. Treating flax fibres etc. 26,906. Nov. 11. (Fr., 9.4.24.)

Stevenson. Manufacture of acetyl cellulose 26,878. Nov. 11.

V.—Complete Specifications Accepted

25,382 (1923). Donagemma, Tofini, Valentini, and Micozzi. Machines for spinning artificial silk. (224,352.)

25,840 (1923). Smith. Process of treating silk. (212,517.)

365 (1924). Courtaulds, Ltd., Clement, and Riviere. Manufacture of threads, filaments, strips, or films from cellulose esters. (224,404.)

366 (1924). Courtaulds, Ltd., and Glover. Manufacture of threads, filaments, strips, or films from cellulose esters. (224,405.)

3112 (1924). Soc. de Stéarinerie et Savonnerie de Lyon. Manufacture of cellulose esters. (219,926.)

16,913 (1924). Bourcet and Regnault. Removing ink from printed paper. (219,311.)

VI.—Applications

Chemische Fabrik Pott und Co., and Pospiech. Wetting-out means for carbonisation, dyeing, etc. 27,047. Nov. 12.

Dean. Dyeing-machinery. 27,310. Nov. 15.

Della Zuana. Machines for mercerising cotton skeins. 27,169. Nov. 13. (Italy, 23.11.23.)

Raduner und Co., Akt.-Ges. Apparatus for use in processes wherein hypochlorites are used. 26,883. Nov. 11. (Switz. 21.9.24.)

VI.—Complete Specifications Accepted

20,068 (1923). Cruse. Impregnation of fibres by electrolysis. (224,285.)

26,029 (1923). British Dyestuffs Corporation, Ltd., Lawrie, and Blackshaw. Production of black shades on cellulose acetate materials. (224,359.)

26,355 (1923). Escaich and Worms. Processes for dyeing or printing fibres of all kinds. (224,361.)

9260 (1924). Joco Rubber and Waterproofing Co., Ltd. Metallised waterproof fabrics. (223,529.)

VII.—Applications

Anjow. 27,129. *See* X.

Compagnie de l'Azote et des Fertilisants Soc. Anon. Preparation of a solution of cyanamide. 27,048. Nov. 12. (Switz., 20.11.23.)

which consists of Representatives from

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals, and the Royal Agricultural Society.

VOL. 43 NEW SERIES | LONDON, OCTOBER 3, 1924 | No. 40

EDITORIAL

WE publish this week letters from two correspondents who treat, in different ways, of the use of the English language. There is loubt that Mr. Rickard correctly indicates the ocratic ideas which tend to prevent the existence ifferent strata in America so far as the language ncerned. There is much to be said for these so far as the ordinary spoken language is cond. A general standard of moderately good ish suffices for the shop, the office and the home. the other hand, where the language is to be used the permanent record of scientific and industrial coveries, for the discussion of abstract scientific s or for purely literary purposes, it is desirable that utmost precision should be attempted, and that ward or ugly phrases should be avoided. Mr. gives some shocking examples of wording which l very easily be improved. Scientific journals ld have a higher standard of accurate and inive writing than that which is required for deng a race meeting or the merits of a patent medi- The future of the English language is in the of those who write it; a large proportion of live in America, and the American writers will e a large measure of praise for examples of ost skilful and elegant use and a corresponding measure of responsibility if their literary s tolerate slovenly writing. The Americans e become exceptionally expert in the use of many ; if they wish to do so there is no reason why should not be as adept as anyone else in the f that superb tool, the English language. Mr. ard certainly has assisted them and us by ritical and scholarly observations on the art of ting.

* * *

Sir Robert Hadfield has called attention to the great loss of time and money occasioned during recent years by strikes and other industrial disputes. The effect of these is far-reaching; a stoppage in one trade usually affects deliveries, orders and payments in several other trades. Vexatious postponements cause irritation and loss shared by the employers, the employed and the public. The Rt. Hon. Mr. Tom Shaw, our Minister of Labour, has had to face this problem continuously ever since he undertook his difficult and almost thankless task. As a means of calling attention to a legitimate grievance the strike is but little more effective than the round-table conferences which he is proposing to arrange in all large disputes of an industrial character. As a means of creating high prices, unemployment and high taxation a succession of long strikes is singularly efficient. There was a time, even so recently as five and twenty years ago, when a strike was practically the only effective measure of protest open to the comparatively feeble trades unions then gradually struggling to obtain control over industry. Circumstances have changed since then; a powerful Ministry of Labour has been organised, every trade has its own confederations, councils and boards. In every trade are many trades union leaders skillful as negotiators and possessing that experience which enables them to realise the burdens which the trade can endure, the share of the gross profits which can be paid as wages without crippling it and having that broad outlook on affairs which enables them to face the huge problems of modern times. In every trade are to be found employers who sincerely desire fair and generous treatment of those who spend their lives in the industry. With all these influences a less expensive method of attaining industrial peace should be possible. There is, of course, a tendency, which we can all understand and deplore, for the rank and file to distrust their leaders more and more as these become abler, more experienced, more sagacious. The young are easily impressed by oratory, by the hope of prosperity to be organised by some league or committee. They resent the advice of those who, with the advantage of an extra thirty years of experience, nevertheless have the disadvantage of being out-of-date or out of sympathy with the fashionable party cries. During the last ten years there has been a significant dislike of law and order, a significant disrespect to contracts and agreements; we are not thinking only of trade agreements but all others. The Senchus Mor, an Irish law book a thousand years old, remarks that there are three occasions when civilisation retreats,

a war, a famine, and a time when agreements are not respected. The observance of agreements is almost as unfashionable as thrift. Both will come into their own again.

Fifty years ago van't Hoff and Le Bel independently originated and published a new conception of chemical structure and chemical combination which has been of fundamental importance to chemistry and particularly organic chemistry. Kekulé had in 1865 propounded the well-known hexagonal ring formation of benzene and Pasteur had vaguely and tentatively suggested the possibility of some tetrahedral spacing of the activities of a carbon atom, but before the work of van't Hoff and Le Bel the consideration of chemistry in connexion with the arrangement of the atoms in space was to all intents and purposes unknown. Van't Hoff, a distinguished Dutch chemist, had studied chemistry under Kekulé at Bonn, and afterwards under Wurtz at Paris, where Le Bel was also studying. Without communication with each other on this subject they independently and almost simultaneously published memoirs which showed that many of the facts of optical activity in organic compounds could be explained quite satisfactorily by assuming that the carbon atom could be treated as tetrahedral in space with its valencies equally separated from each other. This conception has been fruitful and is now universally accepted. It shows how, even in complicated compounds, the various atoms are placed in relation to each other, how in one compound two carbon atoms will lie close to each other and how in another nearly similar one the two carbon atoms may be far distant. The rotation of some substances to the left and others to the right has been satisfactorily explained. In the hands of Baeyer in Germany and Thorpe in this country the doctrine has been extended and elaborated. The asymmetrical carbon atom obscurely imagined by Pasteur and accurately investigated by van't Hoff and Le Bel has proved to be representative of a considerable class of other atoms. Sir William Pope has prepared many optically active compounds containing asymmetrical atoms of tin, nitrogen and other elements. The Dutch Chemical Society and the Dutch Society of Chemical Industry are holding a special meeting in Amsterdam on Saturday, October 25, to celebrate the fiftieth anniversary of the foundation of stereochemistry by the genius of van't Hoff and Le Bel. These Societies have invited the corresponding English Societies to send delegates to this meeting and it is certain that the English men of science will be glad to pay their tribute to the excellent work of their continental colleagues.

We have from time to time raised our voice on behalf of a broad scientific basis for the training of chemists. Dr. Ellis and Professor Drummond have written in our columns, the one showing the danger of expecting chemists to become bacteriologists, the other pleading for the inclusion of biological studies in the preliminary training of all scientific workers. A review of a new textbook on quantitative organic micro-analysis which we publish on another page makes a further contribution to the question. It was Réaumur, we think, who was the first to apply the microscope to the study of metals, but the real foundations of modern metallography were laid by Sorby in 1864, and later, by Heycock and Neville, whose classic work is well illustrated in the Government Pavilion at the British Empire Exhibition. The advances in metallurgy that are due to the use of the microscope are numerous and continually increasing. Yet the chemist has paid but little heed to the service offered by such a valuable aid. Biologists have perforce made use of the microscope and biochemists are well aware of its utility. In a book published not very many years ago, the value of the microscope to chemistry was delimited to the occasional examination of precipitates or fine powders to ascertain if they showed crystalline structure, and even to-day the use of the microscope is associated rather with the study of fermentation than with the analysis of organic compounds. Micro-analysis proffers a tool that the chemist should not hesitate to use and it is surprising that so elegant a tool should still await fuller appreciation. Improvements in technique need to be made, the field of application requires to be broadened, but enough instances of the time, trouble and even money saved by the use of micro-analytical methods could be quoted to show what a gap their lack leaves in the chemical equipment. It is not sufficient, however, to ascribe this deficiency to indifference; the cause lies much deeper, and is to be found in the training of the chemical student. An ideal training for any student of any branch of science cannot be suggested with any hope of gaining general approval, and chemistry is a branch of science that, owing to its complexity and range, provides particularly difficult problems both for teacher and student. This very complexity makes for specialisation, which inevitably means omission, and so micro-analysis is yet pleading for consideration. We at last have a text book which treats the subject thoroughly and in an up-to-date manner, but although we welcome it and anticipate that it will lead to a diffusion of microchemical methods, we cannot but regret that the stimulus should have come from without and not from within.

There is a number of interesting things in the Report of the Committee of the Privy Council for Scientific and Industrial Research, and the curious will find in it details of work on the use of a wavelength of light as a standard of length, of the experiences of the happy band that travelled to Australia and back to ascertain how apples behave on the high seas, and of research on forest products, the carbonisation of coal, problems of illumination, and many other subjects. A further account of Dr. Margaret Fishenden's valuable studies of problems of domestic heating is given and we learn that the work on the domestic coal fire carried out at Manchester is to be transferred to London. Further consideration of the Report must be deferred until a subsequent issue.

INDUSTRIAL FILTRATION.—PART III

By S. G. URE, M.A., B.Sc., M.I.Chem.E.

Among filters using paper as the filtering medium is the Stream-Line filter (Fig. 1), recently introduced by Dr. Hele Shaw. This filter consists of a pack of sheets of impervious paper, having a matte surface and perforated by a number of alternating rows of holes, of large and small diameters, the holes in the outer rows of each sheet being always of the smaller size. These holes are cut so that they coincide with the holes in the sheets immediately above or below, thus forming a pack of filter papers which

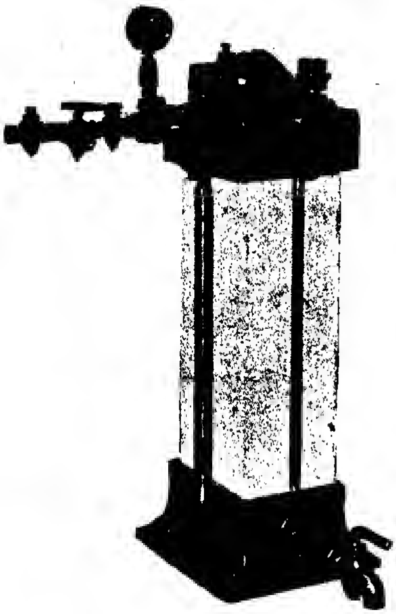

FIG. 1
Stream-line Filter—Vertical Type

is perforated by rows of holes of alternately large and small diameters extending continuously through the pack. The pack is compressed either by screw or hydraulic ram between two metal plates, through one of which the liquor is introduced, and through the other the filtrate and precipitate can be removed from the press. To permit of this, one plate has a series of holes or channels which coincide with the larger holes in the paper, whilst the other plate has two series of holes or channels, one series being in communication with the larger holes and connected with a sump for receiving the solid material, the other set coinciding with the smaller holes and communicating with the outlet pipe for the removal of the filtrate. The liquor, on entering the filter, flows into the larger holes, and as the pressure rises is forced between the sheets of paper which, on account of their rough surfaces, can never be squeezed into perfect contact with each other, and is collected in the smaller openings and passes to the outlet. The solid matter is retained on the inside of the inlet tubes, and in some filters can be removed to the pump, without stopping filtration, by an ingenious arrangement of pistons moving inside the tubes. Industrial filters of this type are built up of a number of units, each capable of filtering about 200 gallons of liquor per hour. The Stream-Line Filter Co. is also developing the continuous rotary filter illustrated in Fig. 2. In this machine eight packs of paper are fitted radially into a circular frame. Each pack consists of about four thousand strips, each strip being about 5½ in. long by 1 in. wide, and perforated with 9 holes about ½ in. in diameter. The alignment of the pack is controlled by two rods inserted in the end holes. A nut acting on a screwed rod attached to the lower block adjusts the pressure on the pack by moving the upper block, which is in contact with the top strip of paper. The lower block, of similar size to the upper, is in contact with the bottom strip. Each of these blocks has the same length and breadth as the paper strips, so that their outer surfaces lie in the planes formed by the edges of the paper. The lower block has a series of holes or a channel which coincide with the holes in the pack. These holes are connected with a central tube which fits into one of eight holes in the hub of the wheel. A bar with a slot attached to the under-side of the lower block also fits into another hole in the hub, and a tapered cotter driven through the corresponding slots in hub and pin fixes the pack rigidly to the hub.

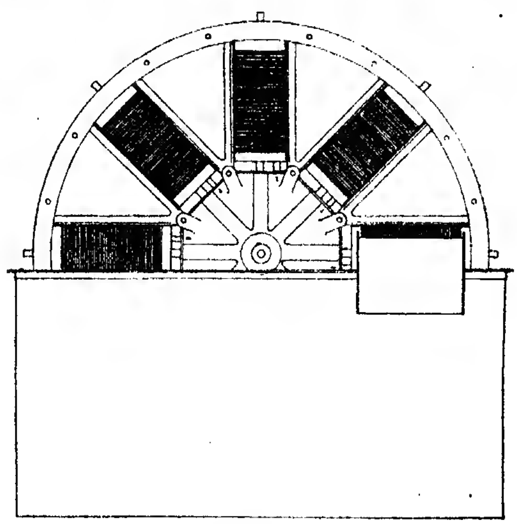

FIG. 2
The Stream-line Rotary Filter

The eight radial holes in the hub meet at the centre of the hollow shaft, which is plugged at one end and connected at the other through a receiver to a vacuum pump. The complete wheel is carried on two bearings, mounted on the top of a rectangular tank containing the liquid to be filtered, thus submerging a considerable portion of the lower half of the wheel. The level of the liquid in the tank is maintained constant by means of a suitably placed overflow pipe, and two knives carried by framing

mounted on the tank scrape the cake off the packs. As the wheel rotates suction is applied to the holes in the pack, the liquor thus drawn through the submerged packs being collected in the receiver. A machine of this type can be seen in action at the British Empire Exhibition. A pulp filter (Fig. 3) manufactured by the Kestner Evaporator and Engineering Co., Ltd., consists of a series of filter plates or frames varying from 20 to 24 in. in diameter, and provided with four ports or channels, two being placed at the top and two at the bottom of each plate or frame. Across the surface of the frame or plate is a number of bars designed to give the maximum area of filtration with the minimum area of unsupported pulp. The filtering medium consists of pure cotton pulp specially prepared for the purpose, pressed into cakes in a suitably designed pulp press. These cakes are held between the frames in such a manner that they form a series of chambers with

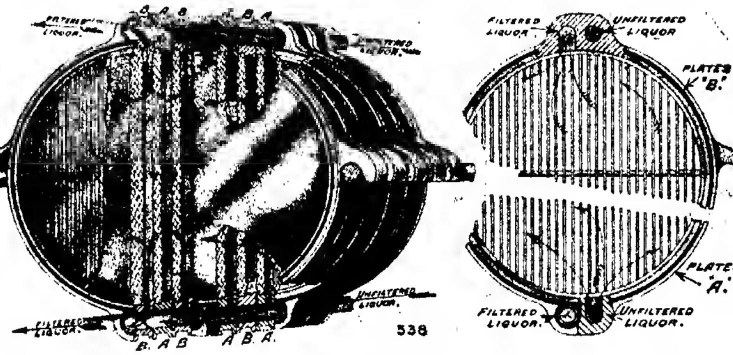

Fig. 3
Kestner Pulp Filter

the frames. Every alternate chamber is connected to the unfiltered liquor channels at the top and bottom of the frame. The other chambers are connected with the outlet channels also situated at the top and bottom of the frames. In this way the liquor enters one set of chambers through two ports in each chamber, and passing through the pulp walls of the chamber into the adjoining chambers, leaves through the filtered liquor outlet channels. The complete equipment for filters of this type comprises washer and steriliser for washing and sterilising the pulp before it is repressed into cakes in the pulp press. With this type of filter, gelatin can be filtered up to a 12 per cent. solution, the machine being suitable for treating such substances as glue, malt extract and fruit juices. Since it is essential that the pressure applied to the liquid in the press should be kept constant, the liquid to be filtered is supplied to the press from a constant level tank, placed from 15 to 20 ft. above the level of the filter.

Centrifugal Machines

As liquor is often separated by means of centrifugal machines from materials such as cotton, wool, or fibrous, granular, or coarsely crystalline products which do not form impenetrable layers on the basket, it is convenient to treat such plant under the title of industrial filtration. Machines utilising centrifugal force to effect the separation may be divided into two classes, the extractor, in which the solid is retained on a porous surface whilst the liquid is forced through by centrifugal force, and the separator, in which the centrifugal force causes the particles to separate into zones of different densities, the particles of the greatest density forming the outer zone. The separator type of centrifugal machine can, therefore, be used for the separation of two or more immiscible liquids.

Extractors

Amongst the well-known firms who manufacture centrifugal machines of the extractor type are T. Broadbent and Sons, Ltd., Huddersfield, Manlove Alliott and Co., Ltd., Nottingham, Pott, Cassels and Williamson, Motherwell, and Watson Laidlaw and Co., Ltd., Glasgow. The essential feature of an extractor machine is a perforated drum or basket which is mounted on a shaft and can be rotated at a high speed. The baskets for these machines consist of cylinders or drums formed of perforated copper, galvanised steel, or monel metal plates, and vary in size from 24 inches in diameter by 14 inches deep to 60 inches in diameter by 24 inches deep or 72 inches in diameter by 18 inches deep. Sometimes the basket is formed by weaving copper or iron wire on a suitable copper or steel frame, which can afterwards be galvanised or tinned. A basket of this type is illustrated in Fig. 4. The baskets are open at the top, and are attached to the driving shafts through the bottom plate, which is sometimes provided with openings through which the solid material can be discharged from the basket. In the underdriven type of machine this bottom discharge is effected through two or more flap-covered openings placed at equal distances from the centre of the basket, but in the overdriven type this discharge opening can be placed in the centre of the basket and covered by a conical shaped valve which can slide on the driving spindle. Baskets on the underdriven type of machine are fitted on the

outside with brake rings, whereas on the over-driven type a special pulley is usually mounted on

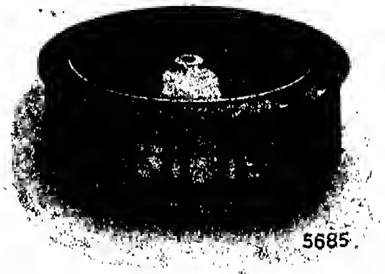

Fig. 4

Woven Centrifugal Basket by Manlove, Alliott & Co., Ltd.

the shaft. Frictional brake blocks, carried on a flexible band, surround the brake rings or pulleys, and can be tightened on to them by hand when stopping the machine. The speed of the basket varies from 1200 to 1500 revolutions per minute for a 24-inch basket to 650 revolutions per minute for a 72-inch diameter centrifugal. The choice of lining for the basket depends largely upon the chemical and physical properties of the material to be treated in the machine. Linings are, therefore made of metal sheets with parallel or conical, oblong or circular holes, of wires of different metals woven into a cloth by spiral or twill weaving, or of cotton and woollen cloths.

Usually three linings are supplied with the machine, the first, next to the shell, consisting of a plain woven lining having four meshes to the inch. This is covered by a plain-woven lining, having seven meshes to the inch and made of brass wire, this being in turn covered by a third lining having a much finer mesh. To retain the liquid thrown from the basket, it is surrounded by a cylindrical casing made of cast iron or other suitable material, and lead lined on the inner surface when the machines are used for centrifuging materials impregnated with acids. The top of the casing is open, whilst in the bottom are situated the holes required for the withdrawal of the discharged liquid and to allow the passage of the shaft and its bearings in the underdriven type. There is a central opening through which the solid material can be discharged in overdriven machines with a bottom discharge. Centrifugal machines may be driven either by belts, reciprocating steam engines, steam turbines, water turbines or electric motors, and the driving mechanism may be situated above the basket (the overdriven type) or below the basket (the underdriven type). When the reciprocating steam engine is used the basket shaft becomes the crank shaft of the engine and in the underdriven type the steam cylinder is bolted to the outer casing of the centrifugal, thus producing a machine which occupies little space and can be readily moved into a suitable position.

In electrically-driven centrifugals of the under-driven type the motor is usually bolted to the bottom of the casing; in the overhead type the motor is carried on a rigid steel framing which may form part of the platform supporting the casing or may be built into the walls of the building. The rotor of the motor drives the basket shaft through a centrifugal clutch or flexible coupling which protects the motor from damage and reduces the starting current required. The advantages in favour of the electrically driven machine are its efficiency, durability, cleanliness, and convenience, and the small space which it requires.

In the water-driven type of centrifugal machine the power is obtained from jets of water acting on a pelton wheel (Fig. 13). Here the water, entering through the pipes 8 and nozzles 7, impinges on the vanes 5 which are fixed to the wheel 2, then, falling into the chamber formed by the casings 3 and 4, passes to waste through the pipe 39. The lower end of the water wheel is bolted to the driver, forming a chamber in which the governor is placed. The

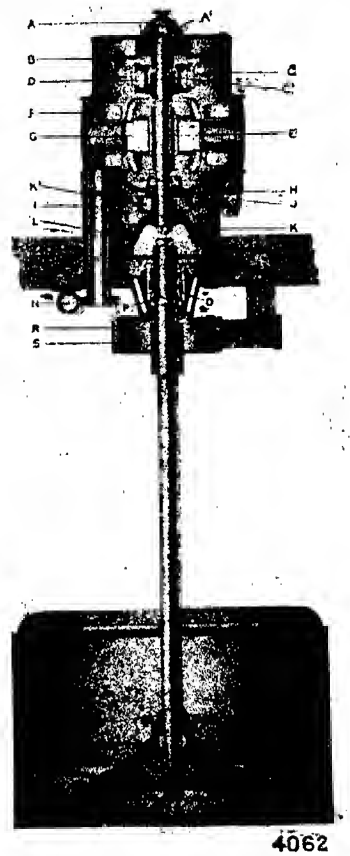

Fig. 5

Electrically-driven Centrifuge by Watson, Laidlaw & Co., Ltd.

governor actuates a tubular spindle 24, communicating with the top of the motor, where it operates

the lever mechanism 15, 16, 17, 18 controlling the water supply to the jets. The lower portion of the figure illustrates one method of supporting the weight of the spindle and basket in a machine of the overdriven type and shows a form of flexible coupling employed between the motor and centrifugal shafts. When this type of drive is adopted, it is advantageous to work the centrifugals in two sets, one of which cannot come into action until the first set has attained the maximum speed, as during acceleration the power required is greater than that for steady running. Pott, Cassels and

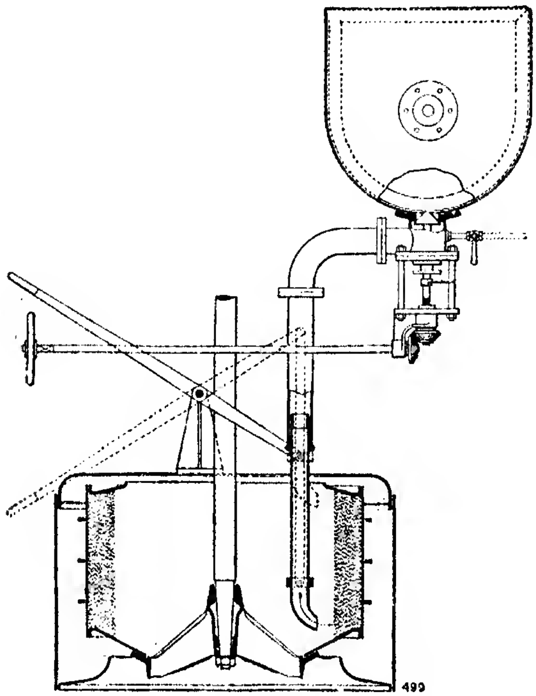

FIG. 6

Feeding device for mobile liquors by Pott, Cassels and Williamson, Ltd.

Williamson supply a patent interlocking gear so designed that only one-half of the machines in an installation can be accelerating at the same time, thus reducing the size of the pumping plant required without interfering with the output of the centrifugals.

When centrifugals are treating solid materials, such as in the extraction of water from cloths, the loading and unloading has to be done by hand with the machine at rest. If, however, the material under treatment contains small particles which can be carried by the liquor the machine can be fed whilst in motion. In order to get the crystals in a mobile mother liquor to rise up the wall of the basket it is necessary to feed the liquid into the basket at a definite velocity by means of a pipe capable of vertical movement which will discharge the liquid against the wall of the basket. Such an arrangement is illustrated in Fig. 6.

For the purification of the solid material retained in the basket steam and water sprays can be fitted inside the basket. Sometimes also steam sprays are fitted in the annulus formed by the casing and the basket, and are used for cleaning the perforations and the inner surface of the casing. The commonest method of discharging the basket is through an opening or openings in its base, the material being shovelled through these after the stoppage of the machine. To obviate this labour of removing the material from the sides of the baskets self-discharging baskets have been designed. In this case the bottom of the basket slopes downward at an angle greater than the angle of repose of the material. A conical disc attached to the spindle at about the mid-point of the depth of the basket acts as a spreader for the incoming material, causing it to be thrown against the middle portion of the basket wall. On stopping the machine the dried crystals slide down the inclined surface and are discharged through the central opening in the bottom of the basket. Another type of basket, suitable only for the underdriven machine, is provided with two projections to which lifting tackle can be fixed and the basket removed from the casing and emptied. Recently a patent has appeared aiming at the discharge of the solid matter from the basket whilst in motion, thus obviating the loss of energy required to start up the machine every run. The bottom of the basket in this machine is conical in shape, the apex of the cone, which points upwards, carrying a shaft provided with a sleeve which can be raised or lowered by a system of levers, whilst the machine is in motion. Attached to the lower end of this sleeve is a second hollow cone whose lower edge is fixed to a disc having a diameter a little less than the diameter of the basket. A piece of cloth the depth of the basket is sewn to form a tube having a diameter equal to the diameter of the basket. The upper end of this tube is attached to the rim of the basket and the lower end to the rim of the disc. The cone having been lowered to the bottom of the basket and the centrifugal started the liquor is admitted. When a sufficient amount of solid material has been deposited on the cloth the cone is raised until the disc of the cone is at the same height above the rim of basket as it was originally below, thus reversing the cloth, so that the solid material now on the outer surface is thrown by centrifugal force into a suitable receptacle on the top of the casing. After discharge the cone may be lowered and the cycle of operations repeated.

Centrifugals may be classified as fixed spindle or free spindle machines. In the former type two bearings rigidly attached to the casing and the sole plate are provided, the lower bearing being designed to act as a footstep and carry the weight of basket and spindle, whilst the upper bearing acts as a guide, and should be provided with an adjustment for controlling the play between spindle and bearing, thus preventing vibrations being set up when the basket is not properly loaded. In the older machines these bearings were of the plain gunmetal bush type, well lubricated, but in modern machines ball or roller bearings carried in dustproof housings are

largely used. A machine of the fixed spindle type requires very good foundations as any out of balance weight may produce unpleasant vibrations which are immediately communicated to the foundations. Therefore to render machines of this class capable of being placed on upper floors or in positions where good foundations are impossible the "suspended" type of machine has been introduced. Here a base ring having three short columns is used, the driving

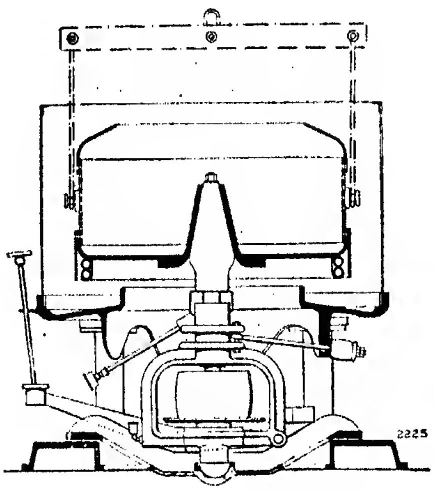

FIG. 7

Peg-top Centrifugal Machine by Manlove, Alliott & Co., Ltd.

gear of the casing basket being suspended from these columns by bolts which are free to take up any vibration produced by running the machine and prevent its transmission to the floors or foundation. In the free spindle type the spindle can move with any lateral movement of the basket and therefore with machines of this class greater care in loading is necessary. When loads are difficult to balance the balancing may be effected by hollow anchor rings containing mercury or other liquid fastened round the basket. Since the rotating basket and spindle of the underdriven type of machine of this class resembles a spinning top the machine is sometimes called a Peg Top centrifugal (Fig. 7). Machines of this class are also fitted with a buffer, which tends to restore the spindle to the upright position and at the same time should have sufficient frictional resistance to prevent the basket from wobbling. The Weston overdriven self-balancing centrifugal is another free spindle machine of the type usually adopted for free spindle machines requiring baskets of large diameters, since the top of the basket in a large underdriven machine would be at an inconvenient height above the floor. These Weston machines are also provided with buffers usually made of rubber, although the buffer effect is sometimes attained by the extension of the spindle, fitted with a shoe which slides in a spherical surface carried on the base of the machine.

SEPARATORS

The speed of these machines varies from 2000 revolutions per minute for machines of the Gee and Sturgeon types to 40,000 revolutions per minute in the small super centrifuges. The Sharples super-centrifuge made by Super-centrifugal Engineers, Ltd. of the commercial size illustrated in Fig. 8 consists of a plain cylindrical tube, termed a bowl, 36 in. long and 4¼ in. in diameter, which is rotated at 17,000 revolutions per minute. The upper end of the tube is closed by the bowl head, which carries the ports for the outflow of the separated liquids and by which the bowl is hung from a flexible vertical shaft. The lower end of the bowl is fitted with a removable cover so designed that it restricts any tendency of the bowl to oscillate. Removable wings in the bowl keep all parts of the liquid moving with the speed of the bowl. The machine can be driven by steam turbine, belt, or electric motor and when the bowl has reached its normal speed the

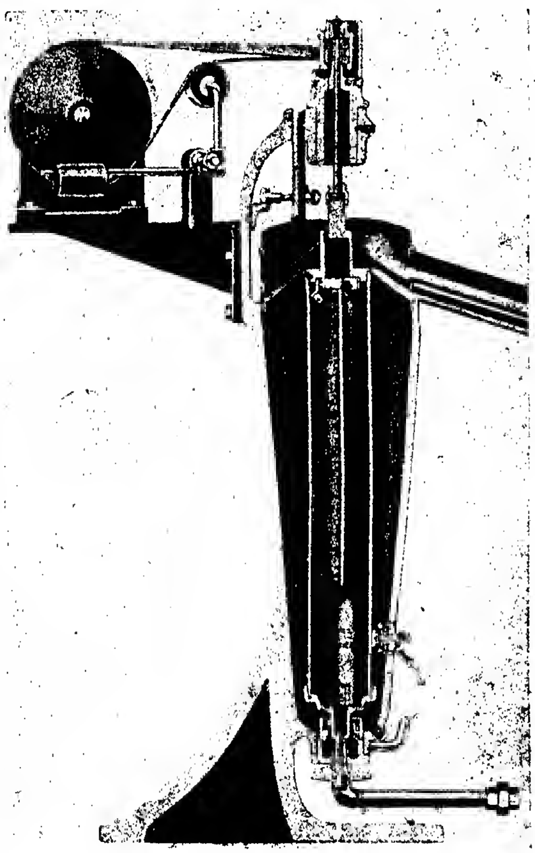

FIG. 8

Sharples Super-Centrifuge by Super-Centrifugal Engineers, Ltd.

liquor is admitted from an overhead tank through a central opening in the bottom cover. The rotation causes the liquid to separate into layers of different densities and as the bowl becomes full these layers ultimately reach the bowl head and flow out through

their respective outlets into collecting trays on the top of the machine. For efficient working with such a machine it is essential that the solid matter in the liquid under treatment should not exceed 1 or 2 per cent., as larger percentages require too much time in proportion to the length of run to be spent in removal, cleaning and replacement of the bowl. Machines, however, have been made for the continuous discharge of the solids, but this is only possible when a second liquid can be obtained which has a greater density than the original liquid and the solids which it contains, and which is immiscible with the original liquid. When a mixture consisting of the solid particles and the two immiscible liquids is fed into the bowl stratification in three layers takes place, the added liquid forming the outer, the solid particles the middle and the original liquid the inner layer, and the heavier outer liquid carries the solid particles with it through its discharge port. This machine can also be used for the separation of two or more liquids, but, as will be readily understood, successful working will be attained when the bowl head has been designed for dealing with the special mixture and it is fed into the machine at a suitable rate.

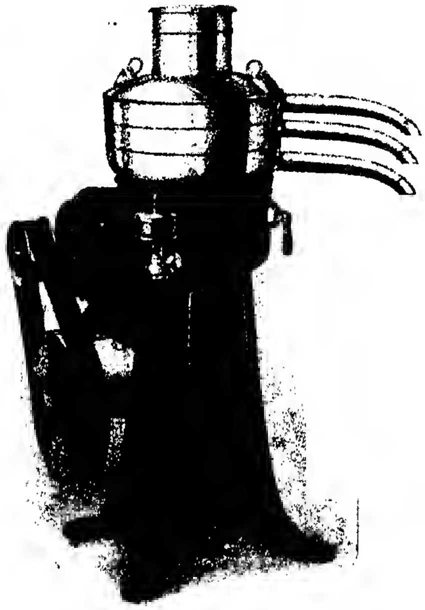

Fig. 9

Vickcen Centrifugal Separator by British Separators, Ltd.

Fig. 9 shows the general external arrangement of a belt-driven Vickeen Separator made by British Separators, Ltd. The liquid being treated passes down a central tube and enters the bowl through a conical distributing plate at the bottom of the bowl. Over this distributor is a number of conical plates having rows of holes round their outer and inner edges. Passages between the plates are formed by radial ribs. The top plate is formed of heavier material and terminates at its upper end in a tube which surrounds the feeding tube. A conical cover secured to the bowl by a cap nut fits over this top plate forming a passage between the upper surface of the plate and the under side of the cover. This passage leads to an annular opening formed by the outer wall of the tubular extension of the top plate and a variable ring held in position by a cap nut on the top of the cover. Several rings are supplied, and in this way the opening can be varied. The liquid on entering the bowl passes by means of the lower holes between the plates. Here separation takes place, the lighter liquid travelling up the cones and entering, through the top holes, the inner annulus, whilst the heavier liquid accumulating on the wall of the bowl is forced up the passage between the top plate and the cover and is discharged through the outer annulus into the lower collecting cover. Such a centrifugal separator running at 60 revolutions per minute is capable of purifying 180 gallons of transformer oil at 50° C. per hour. When the machine has to be used as a super-clarifier the top plate is replaced by one having a shorter tubular extension, and the outer annulus closed by a ring of suitable diameter, thus preventing the escape of the solids and heavier liquid whilst the lighter liquid is discharged into the lower collecting cover. Such an arrangement, whilst giving a clearer effluent, requires more frequent cleaning of the bowl.

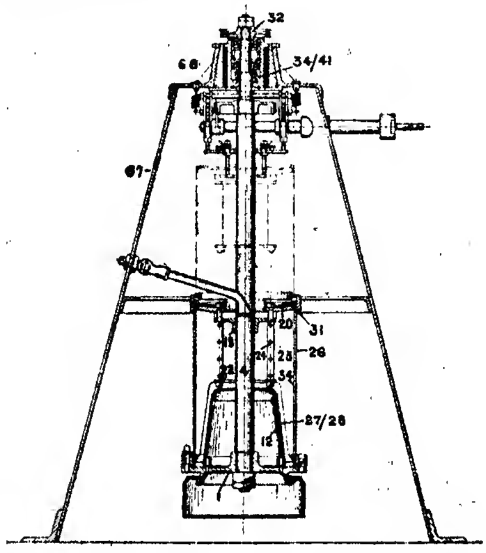

Fig. 10

Gee Centrifugal Separator by British Separators, Ltd.

In the Gee centrifugal (Fig. 10), a specially designed bearing is mounted on the top of a steel plate forming the cover of a hollow truncated cone. This bearing carries a vertical shaft, to the bottom of which is fixed a circular disc perforated at the centre. Below

this disc and free from it is the collecting-box attached to the outlet pipe, whilst on the upper side of the disc is a perforated filtering cone provided with a clamping device by which the filtering medium can be attached to its outer surface. A bayonet fitting allows the drum *l* to be easily attached to the rim of the disc. The top of this drum is covered by a plate having a large central hole through which the liquid is fed into the drum. When the machine removed and replaced by the second set supplied with the machine. It is found that the solid particles deposited on the plates are graded, coarse particles being deposited at the top and fine particles at the bottom. The machine can be easily adapted for centrifuging liquids which must be kept hot during the operation. There is practically no wear of the filtering medium and a constant rate of feed can be maintained during the charging period. Machines

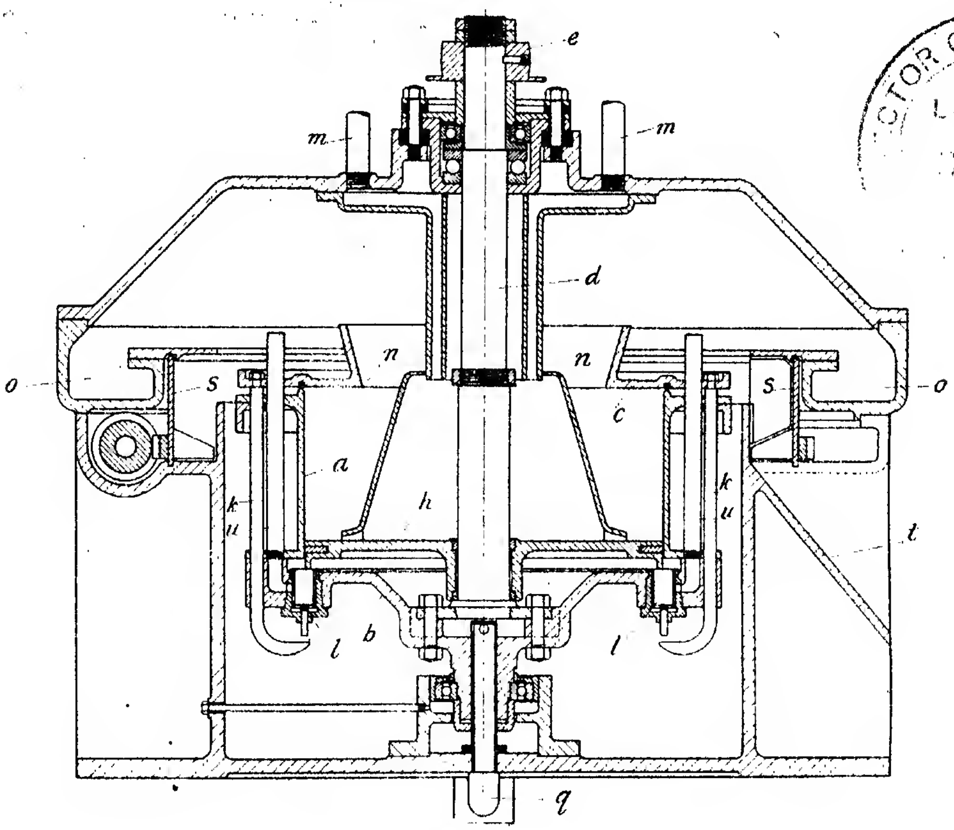

FIG. 11

Sturgeon Centrifugal Machine

is running this plate forms a watertight joint with the drum. Suspended from this plate, immediately below the central opening, is a spreading plate, the six rods attaching it to the upper plate passing downwards and terminating on the middle plate 24. To the top plate, the middle plate, the bottom plate, and these rods are fixed six radial plates which cause the liquid to rotate with the drum and divide the drum into six longitudinal compartments into each of which is fitted a thin plate having the same curvature as the drum and upon which the solid material is deposited. When the plates are charged the container is raised into the dotted position by means of a mechanically driven device carried on the outside of the pedestal. The plates can then be

have been made having drums of 12 and 36 inches in diameter.

One type of the Sturgeon centrifuge (Fig. 11) is a continuous running self-discharging machine. The machine illustrated consists of a vertical shaft, to which is attached the lower cylinder cover *b* and the cylinder *a*. The upper cover can slide on the shaft but is kept in position by the centrifugal force set up by a number of weights actuating bell-crank levers, pivoted on the outside of the cylinder and connected to the cylinder cover *c*. The cylinder is fitted with a piston *h* free to slide on the spindle. The liquid enters the machine at *m* and on reaching the cylinder is subjected to centrifugal force which causes the heavier particles to collect on the cylinder

wall whilst the purified liquid is discharged over the edge *n* into the outlet trough *o*. When sufficient solid has accumulated in the cylinder, the liquor supply is closed and pressure water is admitted through *q* below the piston *h*. As this rises it displaces the liquid still in the cylinder and compresses the solid material on the walls against the upper cylinder cover *c* until this is forced upwards and the solid matter is thrown on to the inner surface of the ring *s* from which it is scraped off into the outlet-chute *t*. The water supply having been closed, the movement of the cover *c* has operated the valves *l* through the rods *k* and the water escapes through the pipes *u*. Admission of liquid at *m* forces the piston *h* down to the bottom of the cylinder closing the valves *l*, thus making the centrifuge ready for dealing with the next change.

Electrical Precipitation

In some electrical experiments Count Schwerin observed that colloidal products collected on the poles, and when similar experiments were repeated on a peat suspension it was found that the dried peat showed a laminated structure, indicating that different materials under the influence of an electric field acquired different velocities. These investigations led to the development of the Osmose filter, which consists of an ordinary type of filter-press made of insulating material. The filter cloths are, however, supported by conducting materials such as wire gauze, which is insulated from the frames. If a difference of potential is maintained between two consecutive supports and the space between the cloths is filled with a clay suspension it is found that the water is discharged at the cathode and a firm cake is formed at the anode in a reasonable interval of time. A rotary machine has also been designed in which the anode consisting of a rotating drum is surrounded by copper strips forming the cathode; the lower portion of the drum being immersed in the liquid.

Recently an article appeared in *La Revue des Produits Chimiques* dealing with the work of MM. Marx and Rozier on the purification of liquids by the simultaneous action of centrifugal force and an electric field. When this principle is applied to a centrifugal of the peg-top type, longitudinal plates are fixed radially to the inner vertical wall. To these plates, but insulated therefrom, is fixed a concentric metal cylinder, thus forming an annulus with the bowl of the centrifugal. All the internal surfaces except the vertical wall of the bowl is covered by some insulating material. The bowl is then connected to one terminal of a dynamo and the inner cylindrical shell to the other terminal. In this way the liquid

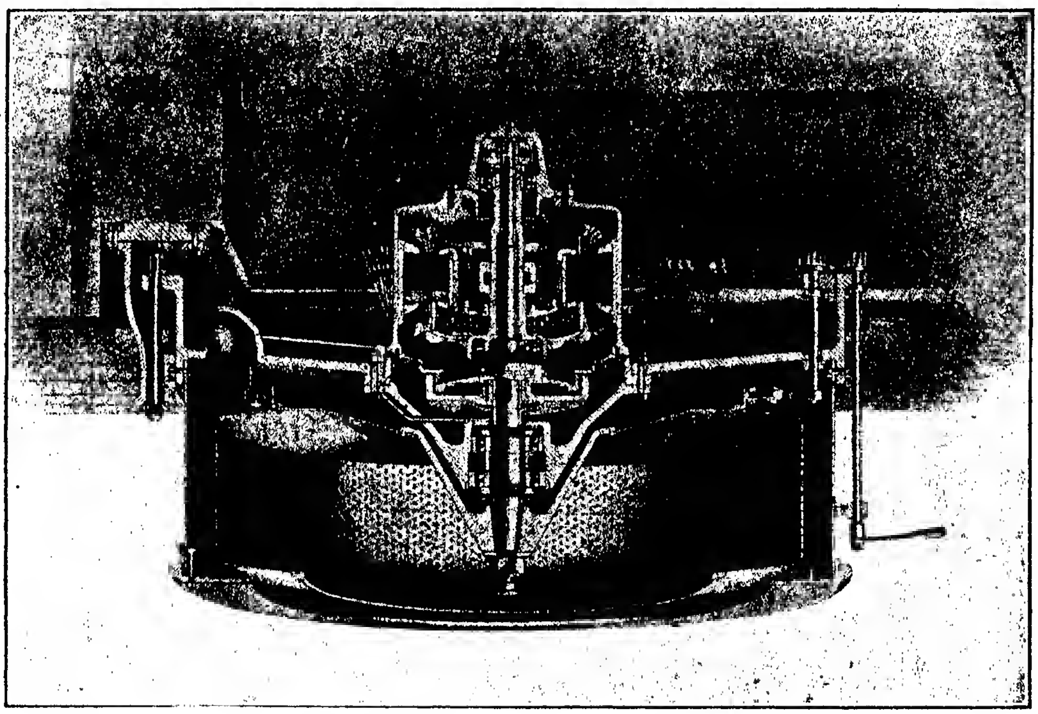

Fig. 12

Suspended, Electrically-Driven Hydro-extractor by Thomas Broadbent & Sons, Ltd.

fed to the bottom of the bowl and rising through the annulus is subjected to the simultaneous influence of an electric field as well as centrifugal force. When the machine is of the Sharples type the bowl itself is coupled to one of the terminals of the dynamo and a concentrically placed metal cylinder, insulated from the bowl, is connected to the other terminal. The authors show that transformer oil which had a rupture potential of 19,000 volts across a 10 mm. gap, had this rupture potential raised to 30,000 volts after 5 minutes' treatment in an electro-centrifuge, whereas the same oil subjected to the same treatment in an ordinary centrifuge of the same type, had the rupture potential raised to only 22,000 volts.

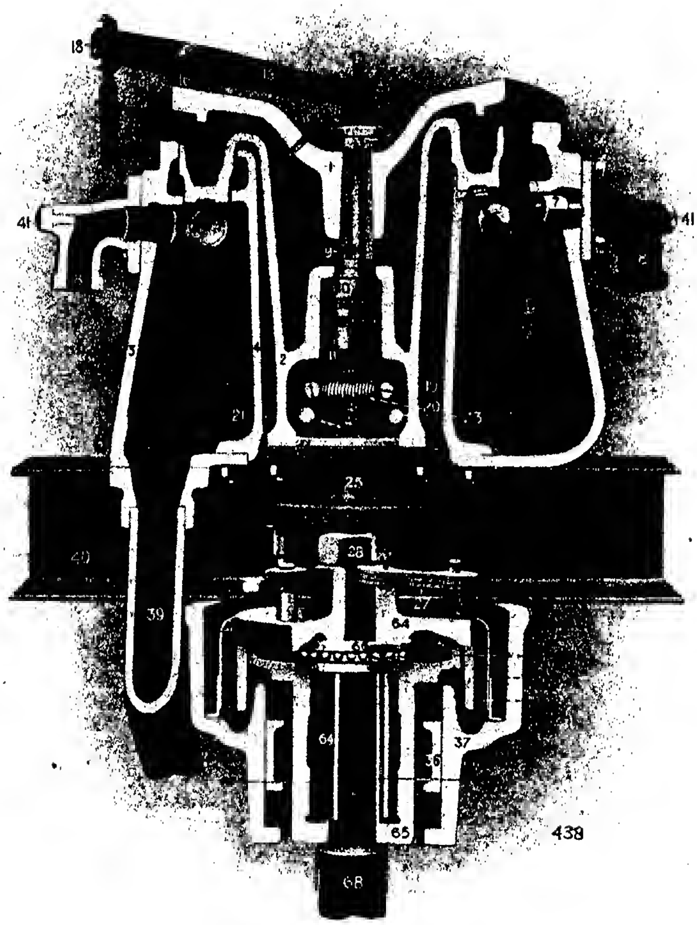

FIG. 13

Pelton Wheel and Top Bearing of Over-driven Centrifugal by Pott, Cassels and Williamson

principle can also be applied to machines of the Vickeen type, by forming each plate of two metal plates separated by an insulating material. The under sides of these plates are electrically connected to the base of the bowl which is in turn connected to one terminal of the dynamo, whilst the upper plates are connected to the cover and wall of the bowl, which are insulated from the base and so to the other terminal of the dynamo. Experiments by the

The Prospectors, Ltd., a new company, is erecting a salt plant at Bucklaw, Victoria Co., Nova Scotia. The output will be largely employed for salting fish.

FORTHCOMING EVENTS

Oct. 6. INSTITUTION OF THE RUBBER INDUSTRY, *London and District Section*, the Engineers' Club, Coventry Street, London, W., at 8 p.m. "Sulphur," by E. Anderson.

Oct. 6. THE TEXTILE INSTITUTE, *London Section*, Clothworkers' Hall, 41, Mincing Lane, E.C. 3, at 5.45 p.m. "Misdescription in the Textile Trades," by A. E. Garrett.

Oct. 6. THE SOCIETY OF ENGINEERS, the Geological Society, Burlington House, Piccadilly, London, W. 1, at 5.30 p.m. "Pulverised Fuel," by E. Kilburn Scott, with lantern illustrations.

Oct. 7. INSTITUTION OF PETROLEUM TECHNOLOGISTS, at the Royal Society of Arts, John Street, Adelphi, London, W.C. 2, at 5.30 p.m. "Recent Development in the Art of Cracking," by A. E. Dunstan.

Oct. 7. THE INSTITUTE OF METALS, *Birmingham Section*, Chamber of Commerce, New Street, Birmingham, at 7 p.m.

Oct. 7. INSTITUTE OF METALS, *North-East Coast Section*, Armstrong College, Newcastle-on-Tyne, at 7.30 p.m. "The Structure of Metals in its Relation to Elastic Failure—Part I," by Prof. F. C. Thompson.

Oct. 8. SOCIETY OF CHEMICAL INDUSTRY, *Nottingham Section*, the University College, Nottingham, at 7.30 p.m. The President will deliver an address on "Publicity in Chemical Industry." The address will be illustrated by films—"Coal and its Products" and "Heavy Chemicals." The meeting is open to all interested, and the following topics will be discussed:—(1) The Need of Publicity, (2) Methods New and Old, (3) Publicity as Exemplified by (a) Advertisements, (b) Letters to the Press, (c) Dinners, (d) Press "News," (e) Films, (f) Exhibitions. Light refreshments will be served to members and Associates.

Oct. 8. THE INSTITUTION OF SANITARY ENGINEERS, Opening Sessional Meeting, to be held at the Cabin Restaurant, Caxton House, Tothill Street, Westminster, London, S.W. 1, at 7.30 p.m.

Oct. 9. INDUSTRIAL LEAGUE AND COUNCIL, Crossway Hall, New Kent Road, London, at 7.30 p.m. "Industrial Policy," by G. Bloomfield.

Oct. 9. INSTITUTE OF METALS, *London Section*, Institute of Marine Engineers, 85-88, The Minories, Tower Hill, London, E. 1, at 7.30 p.m. Address by J. L. Haughton.

Oct. 10. INSTITUTE OF METALS, *Swansea Section*, University College, Singleton Park, Swansea, at 7.15 p.m. Address by Captain Hugh Vivian.

Oct. 10. UNIVERSITY OF LONDON, University College, Gower Street, W.C. 1, at 5.30 p.m. "Water Supply and its Purification" (Lecture I), by Prof. S. L. Raskkovitch. Also on October 17, 24, and 31.

Oct. 10. INSTITUTE OF METALS, *Sheffield Section*, the University, St. George's Square, Sheffield, at 7.30 p.m. Address by W. G. Turner.

Oct. 1[illegible]. SOCIETY OF CHEMICAL INDUSTRY, *Nottingham Section*. Annual Dinner, at the Flying Horse Hotel, Poultry, Nottingham, at 7 for 7.30 p.m. Tickets 5s. each, exclusive of wines. Applications not later than October 9.

SOCIETY OF CHEMICAL INDUSTRY

CHEMICAL INDUSTRY DINNER

The Autumn Dinner, which will be under the auspices of the Society of Chemical Industry and the Chemical Industry Club, will be held in the Edward VII Rooms of the Hotel Victoria, Northumberland Avenue, London, W.C. 2, on Friday, November 14, at 7 for 7.30 p.m., and will be presided over by Mr. W. J. U. Woolcock, C.B.E., President of the Society.

A circular letter with further particulars and a form of application for tickets has been sent out to the members.

BACK NUMBERS OF JOURNAL

The General Secretary will be glad to hear from Members or Subscribers who have copies of the *Journal* for January 5, 1923, or January 4, 1924, that they are willing to dispose of to the Society.

EDITORIAL NOTICES

The Society as a body is not responsible for statements and opinions appearing in the JOURNAL.

Members of the Society, and others, are invited to submit original articles, news, notes and other relevant information to the Editor of *Chemistry & Industry*. Such contributions should be clearly written (preferably typewritten with double spacing), and be accompanied by a stamped and addressed envelope. They will be paid for if inserted. Sources of information should always be given, not necessarily for publication.

Hon. Secretaries of Local Sections and of other Societies are asked to forward notices and reports of meetings as early as possible, and publishers to send books for review, direct to:—THE EDITOR, *Chemistry & Industry*, SOCIETY OF CHEMICAL INDUSTRY, CENTRAL HOUSE, FINSBURY SQUARE, E.C. 2. Telephone: Clerkenwell No. 2429.

Hon. Secretaries of Local Sections and of other Societies are asked to note that announcements of forthcoming events cannot be inserted in the next issue of the JOURNAL *unless they are received not later than Tuesday in any week.*

Matters relating to the Transactions and Abstracts, including Papers intended for insertion as Communications, should be addressed to THE EDITOR OF TRANSACTIONS, at the same address.

LONDON SECTION

The following provisional arrangements have been made: November 3, address by the President (Mr. W. J. U. Woolcock); November 17, Joint meeting with Rubber Institution; December 1 Joint meeting with Oil and Colour Chemists' Association; February 2, Prof. W. A. Bone on "The Constitution of Coal." Times and places of meetings will be announced later.

THE CERAMIC SOCIETY

The autumn meeting of the Refractory Materials Section of the Ceramic Society was held at Wembley on September 18 and 19, with Mr. J. Holland in the chair.

The first item on the programme was a paper by Mr. T. W. Barley entitled "A Comparison of Gas and Coke Fired Drying Stoves." An account was given of the successful use of town gas for drying large moulds in steel works until post-war conditions made it far too expensive. Eventually some experiments were made with the Hüttenes coke-fired, air-blown furnace, and this with some minor modifications has been found very satisfactory. The brick-built furnace is placed at one end of a drying chamber, and the hot gasespass from the furnace upwards on each side of firebrick louvres, between which they are met by a pre-heated jet of compressed air at 80 lb. pressure per sq. in., the products of combustion being thus projected into the drying chamber at a high velocity. Advantages accompanying the use of this type of furnace for drying moulds include economical fuel consumption, little attention required during the run, easy regulation of the temperature by turning on more or less air, economy in space as well as in cost of construction and maintenance, no chimney required, the possibility of placing the furnace at some distance from the drying chamber without serious loss of heat, the guidance to the operator afforded by a satisfactory thermographic chart which may be closely copied, the possibility of using the cheapest available fuel above the grade of dust, the attainment of complete combustion and the possibility of employing ordinary unskilled labour to operate the furnace. These claims are justified by the performance of these furnaces for the past ten months. The efficiency of the apparatus is testified by the fact that all the moulds are thoroughly dried at the end of the run of 15 hours, no mould being found burned or imperfectly dried. The average working temperature employed for mould drying is 225° C., for large cores 200° C., and for small cores 180° C.

The second paper was by Mr. H. S. Houldsworth, M.Sc., on "Some Properties of Clay-Sillimanite Mixtures." The results are given of work undertaken to study the changes in the physical and chemical properties of a clay when mixed with different percentages of sillimanite. The natural commercial sillimanite used contained 32·9 per cent. of silica and 64 per cent. alumina with ferric and titanic oxides. The grading ranged from 11·8 per cent. of material between 5-mesh and 10-mesh size through nine intermediate grades to 18 per cent. of material which passed through a 200-mesh sieve. Test pieces were made of mixtures of Farnley fireclay and sillimanite containing 0, 20, 33⅓, 50 and 66⅔ per cent. of sillimanite respectively, and also others containing 95 per cent. sillimanite with 5 per cent. ball clay, and 90 per cent. sillimanite with 10 per cent. ball clay respectively. The fireclay and ball clay were first ground to pass a 20-mesh. The specimens were fired in a works kiln to cone 6 in 48 hours and to cone 9 in 72 hours, some of the latter test-pieces being subsequently burned for 2 hours at cone 14 and cone 18 respectively in a laboratory gas-fired furnace after reaching the temperature in 3 hours. The drying and firing shrinkages, porosity, true and apparent specific gravities, refractoriness, reversible thermal expansion, and resistance to solution by a soda-lime glass and a basic slag were determined. The results of these experiments may be summarised thus: The addition of sillimanite to clay decreases the drying and firing shrinkages, increases the porosity at the higher temperatures of burning, and when 50 per cent. or more is present increases the refractoriness appreciably. A mixture of 95 per cent. sillimanite with 5 per cent. ball clay has a regular coefficient of expansion from 15° to 1000° C., which is not affected appreciably by differences in the firing temperature up to cone 18. The rapid expansions shown by fireclays from 100°—200° C. and from 500°—600° C. are reduced by the addition of sillimanite. The expansion of a typical fireclay from 600°—1000° C. is less than that of sillimanite in the same range. Sillimanite bonded with 10 per cent. of the ball clay has a marked resistance to chemical attack by soda lime glasses and basic slag. Sillimanite-clay mixtures containing less than 50 per cent. of sillimanite are not appreciably more resistant to such attack than is fireclay alone.

Mr. W. Hugill, M.Met., then read a paper by himself and Mr. W. J. Rees, B.Sc., on "The Influence of Exposure on the Chemical and Physical Properties of Certain Fireclays." Experiments were made to investigate the nature of the changes occurring in fireclays exposed for a fixed period to the weather. The samples of clay included (1) a light grey, somewhat sandy, micaceous clay from Durham, (2) a dark-coloured, compact, fine-grained clay from the Sheffield district, and (3) a light grey, very sandy, and micaceous clay from another locality near Sheffield. The clays were spread evenly over the bottoms of wooden boxes, and left exposed for twelve months. From unexposed and exposed clays small bricks were made and tested. The conclusions drawn from the results of tests were that exposure to the weather removes impurities in the clay to a variable extent, depending on their chemical and physical characteristics. It improves the working properties of the silicous clays 1 and 3, but with the more aluminous clay 2, the general properties and, in particular, the workability, are not materially improved by exposure, though some impurities are removed. Bacteria seem to play an important part in the decomposition of sulphides in clays, and possibly such decomposition may be accelerated by inoculations.

Of the papers presented on the second day, that by Prof. W. Vernadsky "On the Action of Heat on Kaolinite and Kaolinitic Clays," and the paper by Drs. Mellor and Scott on "The Action of Heat on Kaolinite and Other Clays" (Part II.), are controversial in character and largely of theoretical interest. The paper by Mr. Rees on "Alumina-Silica Minerals in Firebricks" bears on a particular aspect of the same subject, and Dr. Hadding's paper on "X-Ray Investigation of Clays and Some Other Ceramic Substances" is concerned with a comparatively new

method which gives results which are apparently open to different interpretations in some cases. All these, though interesting in themselves, are scarcely suitable for short notice in *Chemistry and Industry*, and reference must be made to the original papers.

Mr. W. J. Rees, B.Sc., read a "Note on the Storage of Silica Refractories." It has been noticed from time to time that when silica bricks or blocks have been kept without proper protection from weather action, important changes in physical properties have resulted. In a recent case, silica bricks which had been kept in the open for six months spalled badly in use, whilst normal freshly delivered bricks of the same make and having the same texture, specific gravity, etc., were satisfactory. The good bricks had a cold, crushing strength of 3000 lb. per sq. in., whilst that of the stored bricks was only 2200 lb. per sq. in. Tests were made with bricks, some of which had been left fully exposed to the weather for four months. The results of tests gave definite indications that the loss in strength of silica bricks exposed to weather is in part due to a slight degradation of the bond by hydration and solution in water, as well as to the physical effect of frequent wetting and drying. These tests showed little or no distinction in the behaviour of coarse and fine textured bricks, but in both cases the bricks burned at higher temperatures were more resistant to action by water.

A joint paper by W. Hugill and W. J. Rees on "A Rapid Method for the Determination of True (or Powder) Specific Gravity" includes a description of the apparatus used. This consists of a conical flask, with a long neck at the lower end of which is a wide bulb. At the bottom of the neck is the 250 c.c. mark, and above the bulb the neck is graduated in specific gravities from 2·00 to 2·70, so that the specific gravity may be read off directly without calculation. Liquid is poured into the flask up to the 250 c.c. mark, and exactly 100 g. of dry powdered brick is then gradually dropped into the flask. After standing two minutes to let air bubbles rise, the level of the liquid is read on the graduated neck of the flask. Xylene was adopted as the standard liquid for these tests, being chosen because of its low viscosity and surface tension as compared with water and alcohol, as well as its higher boiling point. Crushing the dry brick to pass a 30-mesh sieve enables results to be obtained accurately within 0·01 per cent. A determination takes from 15 to 20 minutes. The flask is obtainable from a glass-blower in Manchester.

The final paper, by Mr. Rees, described "The True Specific Gravity and After-Expansion of Lime-bonded Silica Bricks." Data are given in a graph and table for 40 bricks from North and South Wales, the Sheffield district, North of England, Scotland and France. The following points are noted:—(*a*) For bricks of lime content between 1 and 3 per cent. there is a sufficiently close relation for practical purposes between the true specific gravity (or powder density) and the degree or extent of quartz conversion. (*b*) For bricks of fine and medium texture there is a close relation between the true specific gravity and the after-expansion as determined by the standard after-expansion test. For works purposes, a rapid determination of the powder density of such bricks gives a definite indication of the permanent volume change which is likely to occur during their use. (*c*) For the raw materials which are in use in this country for the making of lime-bonded silica bricks, the grading of the raw material has in general a greater influence on the rate of quartz conversion than variation in the source or type of the raw material itself. (*d*) For coarse-textured bricks containing large fragments of raw material (*i.e.*, ¼ in. and above in diameter) there is not a close relationship between the true specific gravity and the after-expansion. Possibly for coarse-textured bricks the time of heating in the standard after-expansion test is insufficient.

ACADÉMIE DES SCIENCES

On September 8 Dr. Roux communicated an interesting paper by M. Metilnikov on the heredity of acquired immunity. Experiments on a parasite of the bee showed that the first generation produced from parents immunised against cholera were not immune, whereas the third generation yielded 30 per cent. of immunised larvæ, the immunisation increasing progressively until the eighth and ninth generations gave 75 per cent. of immune individuals. The results are of much interest for the study of human immunisation. M. Leclainche communicated a paper by M. Ducloux on the attenuation of the virulence of the anthrax bacillus, work which had yielded interesting results.

On September 15, M. A. Lumière maintained that on continuing to centrifuge toxic sera to a greater degree than was usual in laboratory apparatus, the serum becomes perfectly harmless. In a previous note Dr. Loisel had stated that in the gas given off by springs at Bagnoles de l'Orne there was an unknown emanation derived from a new radio-active body to which he had given the name of "emilium." Continuing this work, Dr. Loisel showed, in a note presented by M. D. Berthelot, that emilium is found with its characteristic radio-activity in the granitic rocks from which issue the thermal springs.

During the meeting on September 22, M. D. Berthelot described an observation by M. Brylinsky on the Michelson effect. Repetition of this experiment carried out recently in America by Miller showed an unexpected displacement of the interference fringes when the apparatus was rotated. M. Brylinsky states that a variation of as little as 0·001° C. in temperature would suffice to explain the phenomenon so that simple contact between the instrument and the observer during the experiment would produce a sufficient variation of temperature to cause the effect.

J. D. McArthur and Co. are to erect a paper mill at Pine Falls, Manitoba. The cost of construction will be $5,000,000 and the initial daily capacity 200 tons.

CORRESPONDENCE

TECHNICAL WRITING

Sir,—The publishers (John Wiley and Sons) of my little book on "Technical Writing" have sent me a series of clippings recording the pleasant discussion that has been appearing in the columns of your valuable journal on the subject of the English language, and the need for improving our use of it. This discussion was started by your friendly review of my book and Mr. Johnson's subsequent demur to the idea of an Englishman consulting "the book of an American author in order to learn how to write our common language correctly." My friend and associate, Mr. Allen, objected to this suggestion, and asserted that Americans might be permitted to assist in improving the use of our language. He suggested that "we on this side of the Atlantic may be credited with contributing to the improvement of good literature," no less than you gentlemen in England. Whereupon my fellow alumnus of the Royal School of Mines, Mr. Picard, disclosed the fact that I was born and educated an Englishman. To complete the humour of the episode, permit me to say that Mr. Allen also is an Englishman (not even yet a naturalised American, as I am) and a graduate of Cambridge. This ought to mollify Mr. Johnson and save the *amour propre* of our British friends. To them I do not hesitate to say that English professional men—engineers and chemists, for example—commonly use our language with more care and skill than my American friends in the same professions. The cause of the difference is not far to seek. In England the sons of professional men go to school with the sons of others like themselves, that is to say, the children of fairly well educated persons. In the United States the sons of engineers and chemists sit alongside the children of the plumber, the carpenter, and the grocer. The result is that plumbers, carpenters, and grocers in this country usually speak and write better English than those engaged in similar occupations in England, whereas the engineers and chemists show no peculiar superiority in this regard. Furthermore, by reason of our democratic ways of living, the engineers and chemists associate in business, as well as in their sports and home life, with persons not as well educated but as intelligent and successful as themselves. We have no language-tight social compartments, whereas you with a social stratification that survives from feudal days are separated into classes, among which are those who use good English and those who use bad English. The tendency in the United States is to level down the top fraction and to raise the lower fraction of the population, the result being a mediocrity in the use of language, as in other things, that is better than the speech and writing of your lower strata but inferior to that of your upper strata. To use a geologic simile, ours is a confused bedding. Such are the advantages and disadvantages of democracy. In the end the spread of education and the generous service of our universities will improve the language and the intelligence of the whole body of the people.

These observations, I hope, will be deemed pertinent to the discussion. Permit me, sir, to conclude by saying that we engineers, using the word in a broad sense, will do well to accept the aid of anyone sincerely desirous of helping us to use with precision and grace the one instrument—language—that we use most.—Yours faithfully, T. A. RICKARD

PATENT SPECIFICATIONS

Sir,—I have read with interest the recent correspondence in *Chemistry and Industry* on the subject of the English language. Considering the inherent difficulties in explaining complex ideas with the greatest *accuracy*, I think that the language usually employed by chemists reaches quite a respectable standard. It is far different in dealing with patent specifications. Ability to write grammatical English does not seem to be a necessary qualification for a patent agent. Patents taken out by foreigners frequently appear to be mistranslated into English in the most clumsy fashion in such a way that the resulting sentences have no clear meaning. In many cases technical terms are translated wrongly. I am not now referring to the ambiguity often met with in patent specifications which may sometimes be deliberate, but simply to clumsy language due, apparently, to ignorance. Here are some choice specimens taken entirely from specifications I have dealt with in the last two or three weeks. "The excess of 25 grams of formaldehyde have to cause the hardening of the resined product. The resined paraoxybenzylalcohol dissolved in ether and to that added a few drops of concentrated sulphuric acid shows the same deep red colour reaction as the ortho compound does." ". . . maintained at a temperature of 100—120° until all aqueous moisture is removed." In another specification, the example for carrying out the process begins with the word "Yellowlac," when obviously a yellow lake is meant, and the same specification contains the phrase, "being emulsioned while still wet with varnishes."

As the Patent Office employs a large staff of examiners, it seems a pity that a reasonable standard of clarity in language and freedom from error in technical terms is not enforced before a patent is granted. In the meantime, I can only suggest that patentees should safeguard themselves when taking out chemical patents by employing only those patent agents who have competent chemists on their staff.—I am, Sir, etc., PERCY MAY

COLLOID CHEMISTRY IN ANTIQUITY

Sir,—The following quotation from Agricola (1561) is an early example of the application of the properties of colloids in a manufacturing process. In his description of the production of salt, he writes: "In order to accelerate the condensation of the brine, when the Master has poured in two casks and as many dippersful of brine, he adds about a Roman

cyathus and a-half of bullock's blood, or buck's blood, or else he mixes it into the nineteenth dipperful of brine, in order that it may be dissolved and distributed into all the corners of the cauldron; in other places the blood is dissolved in beer. . . . When it begins to thicken with the heat, he and his helper stir it assiduously with a wooden spatula, and then he allows it to boil for an hour. After this he pours in a cyathus and a-half of beer."—I am, Sir, etc.,

OBITUARY

OTTO HEHNER

(An Appreciation)

To give a brief sketch of such an eventful life as that of the late Mr. Otto Hehner is no easy task, comprising as it does so many episodes of professional and personal interest. It is only possible therefore to recount a few of them, and the writer can but hope that he has made a wise selection. The deceased passed away from the effects of a tropical fever on September 9 in South Africa, whither he was sojourning—it was hoped only temporarily.

Born at Marienberg, Nassau, in 1853, Otto Hehner was educated at Wiesbaden, where his father, Karl Philip Hehner, was a judge in the appeal court of that town. He was originally intended for the church, but ultimately he became a pupil, and later an assistant of the veteran analytical chemist, Remigius Fresenius.

In 1873 he left his native country and became assistant to Prof. G. Bischof at the Andersonian College, Glasgow, the precursor of the present Glasgow and West of Scotland Technical College. He has narrated humorously the professor's linguistic difficulties, as well as his own, which at first were even more circumscribed, conversations having to be carried on with the aid of a dictionary. These difficulties disappeared however with the arrival of a fresh assistant, a young graduate from Tübingen, who was no other than William Ramsay. Thus commenced Hehner's lifelong friendship with Ramsay.

Early in 1874 Hehner became assistant to Dr. Arthur H. Hassall, a physician at Ventnor, who was one of the first to take up the study of foods, mainly with the aid of the microscope, and it was here that he collaborated with Dr. A. Angell on the chemical analysis of butter. It was here also that he first met Dr. W. J. Sykes. Coming to London in 1877 he established a practice as consulting chemist in Holborn. In 1881 he removed to more commodious laboratories at 11, Billiter Square, at which his extensive practice is still being carried on by his successor, Dr. H. E. Cox.

Throughout his career Hehner took an active part in the proceedings of scientific societies. Becoming a member of the Society of Public Analysts in 1876, his association with that Society was continuous, and it is not too much to say that the high status which the Society now holds is due more to Hehner than to any other man, not even the late John Muter, who may perhaps be regarded as the founder, could claim to have done so much towards its development, and incidentally, for the study of the chemistry of foods and drugs. He served as a member of Council from 1880, was Secretary in 1883—1890, and President in 1891.

He was elected a Fellow of the Institute of Chemistry of Great Britain and Ireland in 1878, and from the first he recognised how much that body could do to raise the status of the professional chemist. Members of the profession in all its branches now know the debt they owe to the Institute, through such men as Hehner, for the fruition of its ideals. He served as Vice-President of the Institute for three separate periods of three years each, was many times an ordinary member of Council and of the various sub-Committees, and he held the offices of Examiner (1895—1899) and of Censor (1901—1903). An original member of the Society of Chemical Industry, he was Chairman of the London Section in 1900—1902, a period during which the writer was Hon. Secretary. It became necessary about this time to appoint a Committee to investigate methods for the detection and estimation of arsenic in food materials and products, and mainly through Hehner's efforts a Joint Committee of the Society of Chemical Industry and of the Society of Public Analysts was appointed for this purpose. The time which the writer devoted in collaboration with his friend to this subject will ever be remembered as well spent. Hehner was a Fellow of the Chemical Society, and during the early part of his career he was an abstractor for the *Journal*.

Hehner had held many public appointments as Public Analyst and Agricultural Analyst. On account of his wide knowledge he was called upon to give evidence concerning foods, etc., before parliamentary committees, as well as to render expert advice in the passing of numerous water bills and gas bills through Parliament. He examined waters and advised on water supplies all over the country. During the war most of the glycerin passed through his hands, and he advised many firms how to improve the quality and increase the output of glycerin without any remuneration to himself. On account of this work Lord Moulton sent him a special letter of thanks for his services to the country. As an expert witness he gave evidence on almost all the most important cases where chemistry was involved.

His published papers cover a very wide field, and most of them are to be found in the volumes of the *Analyst*. They include researches on fats and waxes and all descriptions of foods. He collaborated with Angell, Dupré, Carpenter, Richmond and Mitchell. Far more, however, than his published works are those locked up in his archives, many of which may perhaps be lost permanently as they would be but imperfectly understood without his illuminating personality. A few months before his death the writer endeavoured to persuade him to put together some of his notes on Foods and Drugs. His reply was: "I could write reams, but I won't!"

The writer first became acquainted with Hehner in 1887, at the time when H. Droop Richmond was his assistant. The acquaintance afterwards ripened

into a close friendship, to which the following circumstance conduced. Hehner was an ardent freemason as a member of the "Deutsche Pilger Loge" in London, and he had been in the habit of meeting other members of that Lodge at coffee at the "Mecca" first in Eastcheap and afterwards in Mark Lane. The men who used to foregather at the "Kaffee Tich" were all the old type of Germans, one and all loyal citizens of the country of their adoption. No more kindly man ever existed than G. Vogeler, the Secretary of the Lodge and a member of our Society. When the Brothers Newlands set up in practice in London, they were attracted to the table by the presence of Hehner, and by degrees the "Kaffee Tich" became to some extent a gathering of chemists. Of these, Domeier, G. Haller, Hehner, Guttmann, B. E. R. Newlands and the writer were constant attendants, whilst occasionally A. H. Allen, W. J. Sykes, J. L. Baker, W. J. Pope and other chemists who happened to be in London would drop in. Alas! G. Haller and the writer are the only two surviving members of those who used to attend regularly.

During the period in which Hehner was Master of the Lodge one of the brethren introduced a German nobleman as a member. Hehner, who was at all times averse to the German *Junker*, immediately resigned, nor could all the persuasion of his friends induce him to reconsider his decision.

Hehner was a philosopher: his knowledge of other sciences than chemistry—botany, geology and entomology—was far above the average. He was kind-hearted and generous, ever ready to help with advice or in a practical manner any who came to him—and these were many. He was of a highly emotional, excitable and even impetuous temperament, forming strong likes and dislikes, but never vindictive towards those who differed from him. Yet as a critic he was severe and incisive. When about thirty years ago typing reports became common, Hehner for several years typed his own reports: he had no patience with the ordinary lady secretary. About twenty-one years ago, however, he saw the fallacy of this and engaged the services of Miss Grace M. Dollery, to whom the writer is indebted for much of the information contained in this notice. Hehner himself used to say that the large increase in his practice of late years was largely owing to Miss Dollery's method and tact. His death has removed from the world chemical a figure long to be remembered by a wide circle of his professional brethren and others, to whom, individually and collectively, he was a close personal friend.

ARTHUR R. LING

HENRY GEORGE SMITH

By the death on September 19, at Roseville, Sydney, New South Wales, of Mr. Henry George Smith, Australia loses one of her most eminent scientific men. Mr. Smith, who was born at Littlebourne, Kent, 73 years ago, was for many years Assistant Curator and Economic Chemist at the Sydney Technological Museum, and upon his retirement a few years ago he continued his researches in the Organic Chemistry Department of Sydney University. In collaboration with Mr. R. T. Baker, formerly Curator of the Sydney Technological Museum, he carried out a series of investigations extending over 30 years, which have thrown much light upon the scientific characteristics and economic possibilities of the essential oils and other products of the Australian flora. The main results of this work were published in two volumes entitled "A Research on the Eucalypts and their Essential Oils," and "A Research on the Pines of Australia." Mr. Smith was an unflagging worker, and his original papers, contributed to various scientific periodicals, number well over one hundred. Owing to the bulk of his work having been published exclusively in Australian journals it received fuller recognition in Australia and America than in Great Britain.

Mr. Smith was an original member of the Australian National Research Council, and at various times he filled the offices of President of the Royal Society of New South Wales, President of the New South Wales branch of the Australian Chemical Institute (1922–3) and President of the chemistry section of the Australasian Association for the Advancement of Science. In the last-named capacity he delivered his presidential address on the chemistry of the Australian flora at Wellington, New Zealand, in 1923. He was an honorary member of many British and American scientific corporations, and was recently awarded the Syme Prize of the University of Melbourne as an appreciation of his services to scientific research in Australia. His character was marked by simplicity and sincerity, and he will be remembered as an outstanding pioneer of Australian chemistry.

PERSONAL AND OTHER ITEMS

The Minister of Health has appointed Mr. James Picken, B.Sc., A.I.C., to be an Inspector under the Alkali etc. Works Regulation Act, 1906, in place of the late Mr. Harold Bailey, O.B.E., F.I.C.

Monsieur R. P. Duchemin, president of the Union des Industries Chimiques, has been elected president of the Industrial Group of the Conseil Supérieur National Economique de France.

Monsieur L. Labbé, director of technical education in the French Ministry of Education, has been promoted Grand Officer of the Legion of Honour.

Mr. G. A. Edwards has been appointed demonstrator in chemistry in King's College, London.

Prof. W. E. S. Turner, D.Sc., who is paying a visit to the United States, was entertained to dinner on September 4 by the Pittsburgh Section of the American Ceramic Society.

Dr. J. E. Gilpin, sometime professor of chemistry at the Johns Hopkins University, Baltimore, died on August 25, at Chestertown, Md. He will be remembered for his work on the action of chlorides of phosphorus on amides and on the fractionation of crude petroleum by capillary diffusion.

REVIEWS

QUANTITATIVE ORGANIC MICROANALYSIS. By F. Pregl, D.Sc., Ph.D. Translated from the second revised and enlarged German edition by Dr. Ernest Fyleman. Pp. xv+190. London: J. and A. Churchill, 1924. Price 12s. 6d. net.

Accurate analytical work is the foundation upon which all true progress in pure or applied chemistry must be built, and accuracy in analytical operations is in turn dependent upon technique. Microchemistry requires above all else a perfect technique, and, if for no other reason than this, should form part of the curriculum in the training of every chemist. Until the appearance of this translation of Pregl's book we have had no modern work in the English language which could be rightly called, as this book can, a textbook of technique. One cannot but feel that in this country analytical technique does not hold the position it should in our teaching. Microchemical methods are but little known, being to-day confined to the bio-chemists and to a few advanced workers who have recognised for themselves the advantage and the elegance, as well as the accuracy, of microchemical analysis. But there is another aspect of the value of microchemical methods and that is in the training they afford in correct manipulative methods, in scrupulous cleanliness and in the art of handling minute quantities of matter without loss. In offering a welcome to this translation the reviewer recognises that its value does not lie in its appeal to the initiated and converted; it is a book that should be in the hands of every analytical chemist and every serious student; and it should do much to widen the knowledge and appreciation of micro-analytical methods as well as stimulate further investigation with a view to broaden the field of micro-chemistry. To those unfamiliar with the German edition of Pregl's book, this translation will come as a revelation. The reviewer knows of no other work which approaches it in minute detail of technique and manipulation. Far too many descriptions of analytical methods published to-day are so condensed as to be worthless except to the experienced analyst. The beginner frequently obtains results so erroneous as to cause him to lose faith in the methods or he learns faulty methods of manipulation which seriously handicap progress. Pregl's minute detailing of conditions, apparatus and precautions, his full description of manipulation, the discussion of difficulties met with and successfully overcome, offer an inspiring and invaluable object-lesson to all chemists whether made or in the making.

The possibilities of micro-analytical methods in industrial laboratories are manifold, their elaboration and adoption is but a matter of time, whilst their value to the investigator would be difficult to exaggerate. No better introduction to them could be desired than is contained in Pregl's book. Much of the apparatus described is capable of many applications, the general principles have been proven sound and the whole work provides an admirable introduction to the technique of handling minute quantities accurately and with confidence. The translation follows the original with exceptional fidelity and in this loses nothing of Pregl's felicity of description. Indeed, the purist may even complain that in one or two places the translation is too literal and as a result offends, but these few cases are overbalanced by the recogni[illegible] so faithful a translation does convey th[illegible] and feeling of the author. There are b[illegible] in the text and these are of small mo[illegible] cannot but hope that this translation [illegible] the means of inspiring many of our chemists to [illegible] effort after perfection of technique as we[illegible] fuller realisation of the immense import[illegible] of accurate analytical work to progress in bo[illegible] and applied chemistry, and, finally, of the[illegible] of microchemical methods.

H. W. GREENWOOD

A TEXT-BOOK OF INORGANIC CHEMISTRY. Edited by J. NEWTON FRIEND, D.Sc., Ph.D. Vol. II. The Alkali-Metals and their Congeners. By A. J. WALKER, Ph.D., B.A. Pp. xxvi+379. London: Charles Griffin and Co., Ltd., 1924. Price 20s.

The Text-book of Inorganic Chemistry, edited by Dr. J. Newton Friend, advances a step nearer completion with the appearance of Volume II. by Dr. A. Jamieson Walker. This volume deals with Group I. of the Periodic Table—hydrogen, the alkali metals, copper, silver and gold. The ammonium compounds are included after the alkali metals.

The arrangement of the subject matter is on the usual lines. Each element is discussed under the heads of occurrence, history, preparation, physical properties, chemical properties, characteristics of the ion and applications. The chief researches on the atomic weight of the element are then discussed, special attention being paid to modern work. These sections are clearly written, and the treatment is concise and adequate. In the case of the metals there follows a description of the most important compounds and salts of the metal.

Dr. A. E. H. Tutton contributes a short but very interesting summary of the results of his researches on the isomorphism of the alkali metal sulphates and selenates and their bearing on the question of atomic structure.

The treatment of the descriptive part is more on the lines of what one may call the older school of text-book. The wealth of physico-chemical data to which we have become accustomed is lacking here. For example, reversible reactions are not discussed from the point of view of mass action. Quantitative data and equilibrium constants are omitted. No figures are given for the degree of hydrolysis of such salts as the alkali carbonates, cyanides and borates. References bearing on these points are, of course, given, but in a text-book of this nature one might reasonably expect to be informed whether, say, sodium carbonate was much or little hydrolysed in solution. For the properties of solutions of salts generally, such as density, conductivity, viscosity, etc., one is given a reference only. These omissions

are probably dictated by considerations of space, but it is curious to find that for solid salts in many cases rather full (and often widely differing) data are given for density, melting-point, specific heat and even conductivity of the fused salt, in spite of the fact that, compared with the data for the corresponding properties of solutions, these figures are, to say the least, inaccurate and less often required.

With these limitations, which are obviously part of the plan of the volume, however much some may regret them, the author has done his work well. The descriptions are clear and concise, and the numerous references carefully chosen rather than exhaustive. The solubilities of most important salts are given, but there are one or two anomalies. Thus the solubility of potassium hydrogen sulphate is given, but not that of the sodium salt, whilst no solubility data are given for, among others, borax and copper nitrate. There are remarkably few errors in the text. The printing is admirable, and the general get-up of the book a credit to the publishers. An idea of the number of references may be obtained from the fact that the name index extends to eighteen and a half double column pages. A full subject index is also provided. An eight-page table of the dates of issue of the principal chemical journals forms a welcome feature of the volume. JOSEPH KNOX

ANILINE AND ITS DERIVATIVES. By P. H. GROGGINS. Pp. vii+256. London: Chapman and Hall, Ltd., 1924. 18s. net.

This book is one more example of the modern and increasing practice of publishing monographs on single substances or on single parts of processes. The practice arises from the need of the industrial chemist for easily accessible information which shall be both authoritative and complete, and which, owing to the enormous growth of knowledge, he is unable to find in textbooks and dictionaries and cannot always look up in current technical literature.

The present monograph on aniline, which is well produced both as to type and illustrations, is not merely a digest of existing knowledge, but attempts to use the data given as a vehicle "for presenting the business of plant chemistry." There is thus a chapter on flow sheets, and the analysis of costs, and one on thermal factors which, if not set out with the clearness and directness of Mr. K. B. Quinan, illustrates very fairly the methods he advocated in the setting-out of a technical problem in a scientific manner. Following a brief introduction on the beginnings of the dyestuff industry, are chapters on the manufacture of aniline from benzene, in which plant and its working are discussed. Curiously enough the manufacture of nitrobenzene is taken last. The reasons may be surmised, but the inversion of the logical sequence is not helpful to the student for whom the book is intended. The details given are sufficiently full and accurate and there is evidence in this part of the work of first-hand experience of plant which has led the author to give some very useful technical information which is not readily accessible. There is not, however, anything very new, nor do the yields quoted show any advantage over those obtained in this country.

In Chapter IV, eight methods are discussed for the separation of aniline from the reducer charge. The method used in this country, of generating steam for the aniline distillation in a special boiler using the surplus aniline water, is not, on the author's figures, quite the cheapest. It is, however, the cleanest and the healthiest and reduces handling to a minimum.

The remainder of the book is more in the nature of a compilation, and papers which have appeared in scientific and technical journals are freely quoted from. Abstracts from patents, mainly of German origin, are given textually. Under phenylglycine, four German patents are mentioned, but there is no reference to other patents, some of them English, of more recent date, which deal with alternatives to the usual aniline-monochloracetic acid route. One chapter is devoted to the preparation of derivatives of aniline, some of the products being treated summarily, whilst others such as the alkylanilines are considered at some length in a helpful manner. The list given of aniline dyestuffs is incomplete and more accurate information is contained in the "Colour Index" of the Society of Dyers and Colourists. As was to be expected in a book by an American author, special reference is made to the aniline derivatives used as accelerators in the rubber industry.

The book should prove a useful addition to the shelves of the technical chemist, and is certainly interesting by virtue of its insistence on accurate costings and its survey of alternative methods.

A. T. DE MOUILPIED

YEAR BOOK OF THE AMERICAN ASSOCIATION OF TEXTILE CHEMISTS AND COLORISTS. Pp. 165. New York, 1924.

The year book is the only publication of the Association, but reports of sections appear in the American Dyestuff Reporter, just as in England the reports of some societies which have not yet advanced to the position of publishing their own journals appear in the technical press. This association appears to carry out in America similar functions to those of the Society of Dyers and Colourists in this country: thus prizes are given for the solution of technical problems, and a list of American-made dyestuffs is given on similar but less ambitious lines to the Colour Index of the Society of Dyers and Colourists.

The membership of the association is 688 and this is the second year of publication of the year book. Research work is encouraged and reports on the fastness of dyestuffs to light, perspiration, chlorine, etc., are given and standard methods of testing for fastness laid down. These methods are the most interesting part of the volume. It is difficult to understand why this association is not connected with the American Chemical Society, which has its industrial sections and a section devoted to the chemistry of cellulose. In fact, both in England and America there is too much overlapping of societies, and chemists engaged in the textile industries would welcome any effort to simplify the position both as regards meetings of societies and the supply of abstracts. S. H. HIGGINS

COMPANY NEWS

BRITISH GLUES AND CHEMICALS, LTD.

The report for the year ended May 31 announces that, after allowing for depreciation (£31,315) and bad debts, the net profit amounted to £6,293 (£35,814 in the preceding year), to which is added £78,469 brought forward. Out of the total of £84,763, a sum of £76,000 is provided for the estimated taxation liability to May 31 last, the balance of £8763 being carried forward. The dividend on the 8 per cent. cumulative preference shares is in arrear as from October 1, 1921.

SALAR DEL CARMEN NITRATE SYNDICATE

At the recent Government sales of nitrate-bearing lands, the Syndicate purchased two plots estimated to contain 1,756,200 metric quintals of nitrate. The price was roughly £62,000, or 8d. per quintal. The reserves of the Syndicate amount to £85,000.

EVANS SONS, LESCHER AND WEBB, LTD.

A loss of £47,120 (of which £23,005 is accounted for by interest on overdraft) is shown by the accounts for 1923, following a total loss of £113,448 in 1922, including £27,065 for loss on property sold and reserve for further depreciation. The debenture service comes to £3480. There is now an accumulated debit balance to profit and loss of £448,780, and the preference dividend was in arrears for 27 months as at December 31 last. Following the reorganisation of the company it is stated that there has been a steady improvement in the business. The directors report that the company is now on a paying basis. The reconstruction of the capital is under consideration, and the directors expect to be in a position to present a scheme at an early date.

BRITISH CELANESE LTD.

The fifth ordinary general meeting was held on September 25, Sir Harry McGowan, K.B.E. (chairman), presiding. The chairman said that since he last addressed the meeting, when he referred in encouraging terms to the progress then being made and to the general outlook, several factors began to operate against the company. The company had not then established its position in the yarn trade, nor had it put its knitted or woven fabric on the market, and largely depended on the sales of cord. Factory costs were, on the smaller output, relatively high, and were affected by the changes and extensions being made in the factory capacity. Early in the year there was a general stagnation in the textile trades, during which the English markets were flooded with cheap and inferior cord from the Continent. This led to the cutting of prices, which was a serious matter, but though the company was disappointed at the results, due to market conditions, for the second half of the financial year it was convinced the superiority of its product was bound to tell. It therefore spent £37,000, with satisfactory results, in advertising. The sales of yarn, the company's basic product, had steadily developed, so that for September of the present year they were five times as great as those for September last year. The expansion of business had led to the lowering of costs, and the profits so far made in the present year were substantially greater than the total losses made in the year under review. The plant for making circular knitted fabric known as Celanese Trico was being increased by 50 per cent., as orders were in excess of capacity. The difficulties formerly experienced in dyeing had largely disappeared, the dye-house had been extended, and the company now produced 80 per cent. of its own dyes. Outstanding debentures had increased from £300,000 at February, 1923, to £700,000 at February, 1924, the proceeds of which had been expended in increasing spinning capacity and in the installation of knitted and woven fabric plants.

Boots Pure Drug Co., Ltd., announce a quarterly dividend at the rate of 36 per cent. per annum, equal to 1s. 9d. per share.

Bell's United Asbestos Co., Ltd., has declared an interim dividend on the ordinary shares of 6d. per share, less tax.

The Glenboig Union Fireclay Co., Ltd., recommends, after providing for depreciation, a dividend for the year of 15 per cent., less tax.

REPORTS

REPORT ON THE INDUSTRIAL AND ECONOMIC CONDITIONS IN NORWAY, TO MARCH, 1924. By C. L. PAUS, C.B.E., Commercial Secretary, Christiania. Department of Overseas Trade. Pp. 76. H.M. Stationery Office, 1924. Price 2s.

Financial difficulties and labour problems formed the centre of public attention during 1923. The depreciation of the krone resulted in exports being well maintained, though imports also showed an increase. Industries were more active than in the previous year (*cf. Chem. and Ind.*, 1923, 918), but those working for the home market had foreign competition to meet. Large reductions were effected in stocks of manufactured goods, frequently at a loss, and an improved demand is now noticeable. Last winter was better for forest owners than 1922–3; although costs of production fell the price of wood-pulp increased. In general, fisheries had a bad year, debts incurred during the previous good period proving a great handicap, whilst prices of fishery produce fell.

A scheme has been put forward to bring the supply of electric power under public control. No new hydro-electric schemes were commenced in 1923, but some schemes were completed. The question has recently arisen as to the feasibility of exporting hydro-electric power to Denmark.

An improvement was noted in 1923 in the import trade, which was greater than in any year since 1920. This was due to decreased stocks and also to increased activity in some industries leading to a demand for raw materials. In general, imports are obtained from those continental countries with depreciated currencies, Britain and America being at a disadvantage in this respect. Textiles were obtained principally from Germany, but Britain

increased her trade. In the metal trade there is little business between this country and Norway. The cellulose and paper-making industries showed an improvement which resulted in restoration of the demand for heavy chemicals; most of this trade was done with Germany.

In spite of great difficulties the position of most industries improved in 1923. The pulp and paper industries did fairly well, exports of pulp and paper totalling 913,389 tons. Output in the mining industries increased somewhat, 300,000 t. of iron ore and 400,000 t. of pyrites being exported. Molybdenite production was recommenced at one mine with a view to export to Britain. Explosives factories in addition to extending their home trade have found outlets in the Black Sea and South American markets. Some improvement was noted in the electrochemical and electrometallurgical industries, chiefly on account of British demands for carbide; the removal of restrictions on the importation of ferro-alloys into Germany was also of assistance. Exports of aluminium were 12,778 t. in 1923, practically double the 1922 figure, though the zinc industry had a bad year.

Report on the Economic and Industrial Conditions in Lithuania, dated April, 1924. By H. H. Cassells, H.M. Consul, Kovno. Department of Overseas Trade. Pp. 28. H.M. Stationery Office. 1924. Price 1s.

Although the political situation was disturbed during the whole of 1923, the revenue showed a favourable balance, and foreign confidence in the country is indicated by loans from the United Kingdom and Sweden, not of money but of manufactured goods. The situation has retarded industrial developments in Lithuania, but most of the pre-war companies and factories are in operation on a reduced scale. About half the factories produce foodstuffs and beverages, this branch employing 1500 workers in all. Timber and paper are partly manufactured, but some finished paper is made. The metal industries are much below pre-war standard and textile manufacture is undeveloped. The country is essentially agricultural, the chief products being cereals and flax, of which considerable quantities are exported. Plans are being made to develop the other agricultural resources of the country, such as dairy produce.

During 1923 exports totalled 146,794,700 lits (the lit varied between 43 and 47 to the £), against 16,892,400 lits in 1922, and imports 156,627,000 lits against 74,884,600 lits. Of the imports in 1923 textiles formed 31 per cent., foodstuffs 20 per cent. and machinery 14 per cent. Of the total, 81 per cent. was supplied by Germany, and only 5·3 per cent. by Great Britain. The chief exports were timber and foodstuffs, of which Germany took 53 per cent. and Great Britain 27 per cent. Although the imports returned as from Great Britain are so small, in reality they were more owing to dealings through Germany, and there seems to be no reason why an increase should not take place, especially in textiles and coal.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech.	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder	£47 per ton.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Copper Sulphate	£25 per ton.
Methylated Spirit 64 o.p.—	
Industrial	2s. 7d.—2s. 11d. per gallon, according to quantity.
Mineralised	3s. 8d.—4s. per gallon, according to quantity.
Nickel Sulphate / Nickel Ammon. Sulphate	£38 per ton d/d. Normal business.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¾d. per lb.
Potass. Chlorate	3d.—4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£3 10s. per ton d/d.
Soda Caustic, solid	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton, carr. paid.
Sod. Bichromate	4¼d. per lb.
Sod. Bisulphite Powder 60/62%	£17—£18 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst.	£9 per ton d/d.
Sod Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—
- Golden .. .. .. 5¾d.—1s. 4d. per lb., according to quality.
- Crimson .. .. 1s. 3d.—1s. 6d. per lb., according to quality.

Arsenic, Sulphide, Yellow 1s. 11d. per lb.
Barytes .. .. .. £3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide .. 3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide .. £30—£33 per ton, according to quantity.
Carbon Black .. .. 7d.—7¼d. per lb. ex wharf.
Carbon Tetrachloride .. £60—£65 per ton, according to quantity, drums extra.
Chromium Oxide, green .. 1s. 3d. per lb.
Indiarubber Substitutes White and Dark .. 5d.—9¼d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black .. .. £48 per ton, barrels free.
Lead Hyposulphite .. 7½d. per lb.
Lithopone, 30% .. .. £22 10s. per ton.
Mineral Rubber "Rubpron" .. .. .. £16 5s. per ton f.o.r. London.
Sulphur .. .. .. £10—£12 per ton, according to quality.
Sulphur Precip. B.P. .. £56—£57 per ton, according to quantity.
Sulphur Chloride .. 4d. per lb., carboys extra.
Thiocarbanilide .. .. 2s. 6d. per lb.
Vermilion, pale or deep .. 5s. 1d. per lb.
Zinc Sulphide .. .. 7¼d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—
- Brown .. .. .. £12 per ton.
- Grey .. .. .. £16 per ton.
- Liquor .. .. .. 9d. per gall. 32° Tw.

Charcoal .. .. .. £7 15s.—£9 5s. per ton, according to grade and locality.
Iron Liquor .. .. 1s. 7d. per gall. 32° Tw.
1s. 2d. ,, ,, 24° Tw.
Red Liquor .. .. 10d.—1s. per gall. 14/15° Tw.
Wood Creosote .. .. 2s. 9d. per gall. Unrefined.
Wood Naphtha—
- Miscible .. .. 4s. 10d. per gall. 60% O.P.
- Solvent .. .. 5s. 3d. per gall. 40% O.P.

Wood Tar .. .. £4 5s. per ton.
Brown Sugar of Lead .. £43 per ton.

TAR PRODUCTS

Acid Carbolic—
- Crystals .. .. 6½d. per lb. Quiet.
- Crude 60's .. .. 1s. 7d.—1s. 11d. per gall, according to district.

Acid Cresylic, 97/99 .. 2s.—2s. 1d. per gall. Demand fair.
- Pale 95% .. .. 1s. 9d.—2s. 1d. per gall. Not much enquiry.
- Dark .. .. .. 1s. 9d.—2s. 1d. per gall. Quiet.

Anthracene Paste 40% .. 4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—
- Strained .. .. 7½d.—9d. per gall. Quiet.
- Unstrained .. .. 6½d.—7½d. per gall.

Benzole—
- Crude 65's .. .. 7½d.—9d. per gall. ex works in tank wagons.
- Standard Motor .. 1s. 1½d.—1s. 3d. per gall. ex works in tank wagons.
- Pure .. .. .. 1s. 5½d.—1s. 7d. per gall. ex works in tank wagons.

Toluole—90% .. .. 1s. 5d.—1s. 5½d. per gall. Small demand.
- Pure .. .. 1s. 8d.—2s. per gall. Small demand.

Xylol coml. .. .. 2s. 3d. per gall.
- Pure .. .. 3s. 3d. per gall.

Creosote—
- Cresylic 20/24% .. 8½d. per gall. Better demand.
- Middle Oil .. .. } 5d.—6½d. per gall., according to quality and district. Market quiet.
- Heavy Oil .. .. }
- Standard Specification }

Naphtha—
- Solvent 90/160 .. 11d.—1s. 2d. per gall., according to district.
- Solvent 90/190 .. 11d.—1s. per gall. Not much demand.

Naphthalene Crude—
- Market dull. Not much export inquiry. Cheaper in Yorkshire than Lancashire.
- Drained Creosote Salts £4—£6. Quiet.
- Whizzed or hot pressed £7—£9 per ton.

Naphthalene—
- Crystals and Flaked .. £12—£16 per ton, according to district.

Pitch, medium soft .. 40s.—50s. per ton f.a.s.
Pyridine—90/160 .. 19s. per gall. Steady demand.
- Heavy .. .. 12s. per gall. Market dull.

INTERMEDIATES AND DYES

Improvement in dyestuffs business maintained but orders are still only for small quantities. Consumers stocks probably very low.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 7d. per lb.
Acid H. .. .. .. 3s. 11d. per lb. 100% basis d/d.
Acid Naphthionic .. 2s. 2d. per lb. 100% basis d/d.
Acid Neville and Winther 5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech. .. 1s. 1d. per lb. Improved demand.
Acid Sulphanilic .. 9½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd. 1s. per lb. d/d.
Aniline Oil .. .. 8d. per lb. naked at works.
Aniline Salts .. .. 8½d. per lb., naked at works.
Antimony Pentachloride 1s. per lb. d/d.
Benzidine Base .. .. 4s. per lb. 100% basis d/d.
Benzyl Chloride 95% .. 1s. 1d. per lb.
p-Chlorphenol .. .. 4s. 3d. per lb. d/d.
p-Chloraniline .. .. 3s. per lb. 100% basis.
o-Cresol 19/31° C. .. 4½d. per lb. Rather quiet.
m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline .. .. 3s. per lb.
Dichloraniline S. Acid .. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol .. .. £85 per ton.
Diethylaniline .. .. 4s. 6d. per lb. d/d., packages extra, returnable.
Dimethylaniline .. .. 2s. 3d. per lb. d/d. Drums extra.
Dinitrobenzene .. .. 9d.—10d. per lb. naked at works.
Dinitrochlorbenzol .. £84 10s. per ton d/d.
Dinitrotoluene—48/50° C. 8d.—9d. per lb. naked at works.
66/68° C. 1s. 2d. per lb. naked at works.
Diphenylamine .. .. 2s. 10d. per lb. d/d.
Monochlorbenzol .. .. £63 per ton.
*β*Naphthol .. .. 1s. per lb. d/d.
*α*Naphthylamine .. 1s. 4d. per lb. d/d.
*β*Naphthylamine .. 4s. per lb. d/d.
m-Nitraniline .. .. 4s. 3d. per lb. d/d.
p-Nitraniline .. .. 2s. 3d. per lb. d/d.
Nitrobenzene .. .. 5½d.—5¾d. per lb. naked at works.

o-Nitrochlorbenzol	2s. 11d. per lb. 100% basis d/d.
Nitronaphthalene	10½d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	3s. 11d. per lb. d/d.
p-Phenylene Diamine	10s. 2d. per lb. 100% basis d/d.
R. Salt	2s. 5d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 3d. per lb. 100% basis d/d.
o-Toluidine	8½d. per lb.
p-Toluidine	3s. 3d.—4s. 2d. per lb. naked at works.
m-Toluylene Diamine	4s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	£47 per ton. Firmer.
Acid, Acetyl Salicylic	3s. 1d.—3s. 3d. per lb., according to quantity.
Acid, Benzoic B.P.	3s. per lb.
Acid Boric B.P.	Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 3½d.—1s. 4½d. per lb., less 5% for ton lots. Market very weak.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	6s. 9d. per lb. Resublimed quality 8s. per lb. Market firm.
Acid, Salicylic	1s. 5d.—1s. 8d. per lb., according to quantity.
Acid, Tannic B.P.	2s. 10d. per lb. Market quiet.
Acid, Tartaric	1s. 1½d. per lb. less 5%.
Amidol	9s. per lb. d/d.
Acetanilide	2s. 1d.—2s. 3d. per lb. for quantity. Demand slow.
Amidopyrin	13s. 3d. per lb. Neglected. Stocks low.
Ammon. Benzoate	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	15s.—15s. 6d. per lb. Quiet market.
Benzonaphthol	5s. 3d. per lb. Small inquiry.
Bismuth Carbonate	10s. 6d.—12s. 6d. per lb.
„ Citrate	10s. 3d.—12s. 3d. „
„ Salicylate	9s.—11s. „
„ Subnitrate	8s. 8d.—10s. 8d. „
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	Market firm.
Ammonium	1s. 6d.—1s. 9d. per lb. } According to quantity.
Potassium	1s. 4d.—1s. 7d. per lb. }
Sodium	1s. 5d.—1s. 8d. per lb. }
Calcium Lactate	1s. 7d.—2s. per lb., according to quantity. Fair demand and steady market.
Chloral Hydrate	4s.—4s. 3d. per lb. Market easier after recent firmness.
Chloroform	2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate	6s. 6d. per lb. Little demand.
Formaldehyde	£49 per ton.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free	7s. per lb.
Glycerophosphates—	
Iron	8s. 9d. per lb.
Magnesium	9s. per lb.
Potassium, 50%	3s. 6d. per lb.
Sodium, 50%	2s. 6d. „
Guaiacol Carbonate	10s. 6d.—11s. 3d. per lb.
Hexamine	3s. 1d.—3s. 3d. per lb.
Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor	English make offered, 120s. per oz.
Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. „
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£25 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	53s. 6d. per lb. Cheaper.
Synthetic	26s.—35s. per lb., according to quantity. English make.
Mercurials	Market very quiet.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	3s. 6d.—3s. 7d. „
White precip.	4s. 7d.—4s. 8d. „
Calomel	3s. 11d.—4s. „
Methyl Salicylate	1s. 10d.—2s. per lb.
Methyl Sulphonal	26s. per lb.
Metol	11s. per lb. British make.
Paraformaldehyde	2s. 6¼d. per lb. for cwt. lots. Not very active.
Paraldehyde	1s. 6d. per lb. in free bottles and cases.
Phenacetin	5s. 9d. per lb.
Phenazone	7s. 2d. per lb.
Phenolphthalein	5s. 6d.—6s. per lb.
Potass. Bitartrate—99/100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots.
Potass. Citrate	1s. 10d.—2s. 2d. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Steady market.
Potass. Metabisulphite	7½d. per lb., 1-cwt. kegs included. F.o.r. London.
Potass. Permanganate	7¼d. per lb.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz tins. Steady market.
Saccharin	63s. per lb., in 50-lb. lots.
Salol	3s. 6d.—4s. per lb.
Silver Proteinate	9s. 6d. per lb.
Sod. Benzoate, B.P.	2s. 6d. per lb.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite—Photographic	£13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	75s.—82s. 6d. per cwt., according to quantity. Quiet market.
Sod. Salicylate	Market rather easier. Powder 2s. 1d.—2s. 3d. per lb. Crystal at 2s. 3d.—2s. 5d. per lb. Flake 2s. 9d. per lb.
Sod. Sulphide—	
Pure recryst.	10d.—1s. 2d. per lb.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal	15s. per lb. Easier.
Thymol	17s. 6d. per lb. Very scarce indeed.

PERFUMERY CHEMICALS

Acetophonone	12s. 6d. per lb.	
Aubepine	15s. 3d. ,,	
Amyl Acetate	2s. 6d. ,,	
Amyl Butyrate	6s. 9d. ,,	
Amyl Salicylate	3s. 3d. ,,	Dearer.
Anethol (M.P. 21/22° C.)	4s. 6d. ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 9d. ,,	
Benzyl Alcohol free from Chlorine	2s. 9d. ,,	
Benzaldehyde free from Chlorine	3s. 6d. ,,	
Benzyl Benzoate	3s. 6d. ,,	
Cinnamic Aldehyde—Natural	18s. 9d. ,,	
Coumarin	19s. 6d. ,,	
Citronellol	17s. ,,	
Citral	8s. ,,	Cheaper.
Ethyl Cinnamate ..	12s. 6d. ,,	
Ethyl Phthalate	3s. 3d. ,,	
Eugenol	10s. ,,	Cheaper.
Geraniol (Palmarosa) ..	35s. ,,	
Geraniol	11s.—18s. 6d. per lb.	
Heliotropine	6s. 9d. ,,	
Iso Eugenol	15s. 9d. ,,	
Linalol ex Bois de Rose ..	26s. ,,	
Linalyl Acetate	26s. ,,	
Methyl Anthranilate ..	9s. 6d. ,,	
Methyl Benzoate	5s. ,,	
Musk Ambrette	50s. ,,	Dearer
Musk Xylol	13s. 6d. ,,	Cheaper.
Nerolin	4s. 9d. ,,	
Phenyl Ethyl Acetate ..	15s. ,,	
Phenyl Ethyl Alcohol ..	16s. ,,	
Rhodinol	60s. ,,	
Safrol	1s. 10d. ,,	
Terpineol	2s. 4d. ,,	
Vanillin	26s. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.	
Anise Oil	2s. 8d. per lb.	
Bergamot Oil	17s. 6d. per lb.	
Bourbon Geranium Oil ..	36s. 0d. per lb.	
Camphor Oil	65s. per cwt.	
Cananga Oil Java ..	10s. per lb.	Cheaper.
Cinnamon Oil, Leaf ..	6½d. per oz.	
Cassia Oil, 80/85% ..	10s. per lb.	
Citronella Oil—		
Java 85/90%	5s. 9d. per lb.	
Ceylon	3s. 7d. per lb.	
Clove Oil	7s. 6d. per lb.	
Eucalyptus Oil 70/75% ..	2s. 3d. per lb.	
Lavender Oil—		
French 38/40% Esters	27s. 6d. per lb.	
Lemon Oil	3s. per lb.	
Lemongrass Oil	4s. 6d. per lb.	
Orange Oil, Sweet ..	11s. per lb.	
Otto of Rose Oil—		
Bulgarian	40s. per oz.	Dearer.
Anatolian	18s. per oz.	
Palma Rosa Oil	16s. 6d. per lb.	
Peppermint Oil—		
English	65s. per lb.	
Wayne County ..	30s. per lb.	
Japanese	17s. 3d. per lv.	
Petitgrain Oil	9s. 3d. per lb.	
Sandal Wood Oil—

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before Nov. 24th; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on Oct. 9th.

I.—Applications

Irwin, and Johnson and Co., Ltd. Filters etc. 21,947. 21,948. Sept. 17.

Lumsden, Peddie, and Pirbright Co. Filtering-apparatus. 21,872. Sept. 16.

Marks. Lubricants. 22,260. Sept. 20.

Nisbet and Thomson. Apparatus for filtering dust-laden gases. 22,011. Sept. 18.

Roos. Centrifugal separators. 22,203. Sept. 20. (Dutch East Indies, 20.9.23.)

Sedbery. Grinding-mills. 22,073. Sept. 18.

I.—Complete Specifications Accepted

6579 (1923). Coppee and Co., and Kavau. Rotary furnaces. (206,105.)

14,864 (1923). Burt, Bolton and Haywood, Ltd., and China. Producing disruptive forces in films of liquid or suspensions. (221,548.)

17,014 (1923). Nafilyan. Drying or removing the liquid from solutions or suspensions of substances in liquids. (221,598.)

22,753 (1923). Allsop and Sibson. Drying-machines. (221,641.)

5971 (1924). Hertenbein. Rotary filters. (212,907.)

6968 (1924). Imray (International Combustion Engineering Corporation). Pulverising mills. (221,743.)

8888 (1924). Schofield, Tinsley, and Gall. Optical pyrometers. (221,751.)

10,815 (1924). Baglin. Continuous centrifugal dryers. (221,760.)

II.—Applications

Cuylets. Method for removing water from peat etc. 21,754. Sept. 15.

Gensecke, and Metallbank u. Metallurgische Ges. 21,944. *See* XII.

Koppers Co. Purification of fuel gas. 21,739. Sept. 15. (U.S., 7.8.24.)

Nisbet and Thomson. 22,011. *See* I.

Parker. Distillation of coal etc. 21,910. Sept. 16.

Rheinische Metallwaaren u. Maschinenfabrik. 22,154. Sept. 19.

Rude. Production of water-gas from fuel etc. 21,695. Sept. 15.

II.—Complete Specifications Accepted

8717 (1923). Strafford and Pick. Manufacture of carbonised fuel. (221,526.)

9779 (1923). Thermal Industrial and Chemical (T.I.C.) Research Co., Ltd., and Rider. *See* III.

15,329 (1923). Melamid. Cracking or decomposition of materials containing or yielding hydrocarbons. (221,559.)

19,974 (1923). Humphreys and Glasgow, Ltd. Manufacture of carburetted water-gas. (221,622.)

27,348 (1923). Queneau. Retorts for carbonising solid fuels. (221,679.)

29,084 (1923). Still and Petsch. Coke ovens. (221,697.)

III.—Application

Preiss. 22,132. *See* XIX.

III.—Complete Specification Accepted

Thermal Industrial and Chemical (T.I.C.) Research Co., Ltd., and Rider. Dehydration and distillation of tars or oils. (221,528.)

IV.—Applications

British Dyestuffs Corporation, Ltd., Fyfe, and Perkin. Manufacture of anthraquinone dyestuffs. 21,983. Sept. 17.

British Dyestuffs Corporation, Ltd., Baddiley, Hill, and Riley. Manufacture of azo colouring-matters. 21,984. Sept. 17.

British Synthetics, Ltd., and Higgins. Manufacture of azo dyestuffs etc. 21,862. Sept. 16.

Dehn (Budd Manufacturing Co.). Treating metals. 21,785. Sept. 15.

Farbwerke vorm. Meister, Lucius, und Brüning. Manufacture of vat-dyestuffs containing sulphur. 21,758. Sept. 15. (Ger., 19.9.23.)

Farbwerke vorm. Meister, Lucius, und Brüning. Manufacture of condensation products of the anthraquinone series. 21,876. Sept. 16. (Ger., 18.9.23.)

IV.—Complete Specification Accepted

23,349 (1923). Johnson (Badische Anilin und Soda Fabrik). Manufacture of halogenated vat-colouring matters. (221,643.)

V.—Applications

Bayley. Manufacture of viscose threads etc. 21,959. Sept. 17.

British Celanese, Ltd., and Ellis. Treatment of cellulose acetate. 22,153. Sept. 19.

Courtaulds, Ltd., Glover, and Weyenbergh. Production of cellulose compounds. 21,753. Sept. 15.

Courtaulds, Ltd., Gardner, and Napper. Manufacture of viscose threads etc. 21,958, 21,959. Sept. 17.

Draper. Manufacture of viscose silk etc. 21,960. Sept. 17.

Soc. La Cellophane. Manufacture of cellulose films. 22,168. Sept. 19. (Fr., 23.11.23.)

V.—Complete Specification Accepted

23,678 (1923). Spijker. Treating fibres of fibrous products. (221,645.)

VI.—Applications

Bach. Apparatus for dyeing etc. hanks of yarn etc. 22,235. Sept. 20.

British Dyestuffs Corporation, Ltd., and Mudford. Dyeing fabrics containing acetyl silk. 22,163. Sept. 19.

Park. Proofing-composition. 21,894. Sept. 16.

Thies. Dyeing-apparatus. 22,072. Sept. 18.

VI.—Complete Specification Accepted

2084 (1924). Schumacher. Dyeing of cops. (210,765.)

VII.—Applications

Harris. Treatment of alkali solutions containing tin. 22,054. Sept. 18.

Harris. Treatment of alkali liquors. 22,238. Sept. 20.

Kennedy and Lloyd. Method of making arsenical salts. 21,764. Sept. 15.

Llewellyn, Spence, and Spence and Sons. Treatment of aluminous materials. 22,018. Sept. 18.

Synthetic Ammonia and Nitrates, Ltd. Synthetic ammonia process. 22,091. Sept. 19. (U.S., 19.9.23.)

VIII.—Application

British Oil Products Co., Ltd., Fulton, and Hutton. Treatment etc. of enamels etc. 21,820, 21,821. Sept. 16.

VIII.—Complete Specification Accepted

12,237 (1923). Danner. Regulation of temperature conditions in molten glass. (221,633.)

IX.—Applications

Agasote Millboard Co. Wood substitute. 21,750. Sept. 15. (U.S., 21.2.24.)

Martin. Manufacture of iron cement. 21,853. Sept. 16. (Fr., 17.9.23.)

IX.—Complete Specifications Accepted

17,266 (1923). Berkeley and Stenhouse. Preserving timber and leather. (221,699.)

2269 (1924). Angelis, do. Heat-insulating material. (210,459.)

6857 (1924). Wikkula. Porous concrete. (221,742.)

X.—Applications

Buckle. Powder for welding steel and restoring burnt steel bars etc. 22,232. Sept. 20.

Hendrick. Alloying ferrous metal surfaces. 22,023. Sept. 18.

Marks (Canada British Syndicate, Ltd.). Metal-coating compositions. 22,184. Sept. 19.

Marks (Merco Nordstrom Valve Co.). Alloys. 22,259. Sept. 20.

Tafel. Process of treating ingot iron. 22,049. Sept. 18.

Wüst. Production of tin from alloys containing iron. 21,756. Sept. 15. (Ger., 22.1.24.)

X.—Complete Specifications Accepted

9892 (1923). Mathesius. Production of titanium steel. (221,529.)

17,043 (1924). Western Electric Co., Ltd. (Western Electric Co., Inc.). Metallic compositions. (221,770.)

XI.—Application

Marschalko. Primary batteries. 22,180. Sept. 19.

XI—Complete Specifications Accepted

13,116 (1923). Haddon and Burnett. Accumulator grids or plates. (221,539.)

13,118 (1923). Haddon, Burnett, and Fullilove. Accumulator plates. (221,541.)

21,269 (1923). Shields. Increasing the life of graphite or carbon electrodes. (221,634.)

XII.—Application

Genseke, and Metallbank u. Metallurgische Ges. Process of purifying oils etc. 21,944. Sept. 17.

XIII.—Application

Marks (Canada British Syndicate, Ltd.). 22,184. *See* X.

XIII.—Complete Specification Accepted

15,133 (1923). Johnson (Diamond State Fibre Co.). Manufacture of synthetic gum. (221,533.)

XV.—Applications

Bendixen and Ehrenreich. Process for tanning fish skins etc. 22,169. Sept. 19.

Bergmann and Immendorfer. Process of removing hair from hides. 21,848. Sept. 16. (Ger., 19.9.23.)

XV.—Complete Specifications Accepted

17,266 (1923). Berkeley and Stenhouse. *See* IX.

30,378 (1923). Pansky. Preparation of gelatin. (221,702.)

XVIII.—Complete Specification Accepted

16,781 (1923). Ling and Nanji. Augmenting the yield of alcohol in the fermentation of amylaceous mashes. (221,592.)

XIX.—Applications

Menz. Separation of scale-producers from water. 22,143. Sept. 19.

Posseyer. Clarifying sludge etc. 22,133. Sept. 19.

Preiss. Method of removing phenol etc. from waste waters etc. 22,132. Sept. 19.

XIX.—Complete Specification Accepted

32,627 (1923). Imray (Soc. of Chemical Industry in Basle). *See* XX.

XX.—Applications

Austerweil. Production of terpene alcohols. 22,165. Sept. 19. (Ger., 19.9.23.)

Binz. Method of producing organic compounds. 22,178. Sept. 19.

Hirzel. Process of preparing benzyl resorcinol. 22,090. Sept. 19. (U.S., 19.9.23.)

Naugatuck Chemical Co. Manufacture of styrol etc. 21,751 and 21,755. Sept. 14 and 15. (U.S., 7.5.24 and 24.4.24.)

XX.—Complete Specifications Accepted

15,427 (1923). MacEwen. Manufacture of arsenical therapeutic preparations. (221,565.)

19,981 (1923). Rheinische Kampfer Fabrik Ges. Production of aromatic sulphonic acids. (202,975.)

32,627 (1923). Imray (Soc. of Chemical Industry in Basle). Manufacture of the phosphorus-containing nuclear substance of milk casein. (221,716.)

XXI.—Application

Jos-Pe Farbenphoto Ges. Multiplex colour photography. 21,829. Sept. 16. (Switz., 13.2.24.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number:—*Algiers:* Pharmaceutical chemicals, (338). *Argentina:* Paper, (B.X./1243). *Belgium:* Paper, (326); ironmongery, (327); medical and pharmaceutical supplies, (328). *Brazil:* Chemical products, (344). *British India:* Photographic goods, (318); metal sheets, (The Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, London, S.E. 1); steel material (The Directors of the Madras and Southern Mahratta Railway Co., Ltd., 25, Buckingham Palace Road, London, S.W. 1). *Canada:* Hardware, cutlery, oils, perfumes, soaps, (319). *Chile:* Paper, cement, hardware, (347). *Egypt:* Iron, centrifugal pumps, lead, leather, rubber, brass, copper, (337); iron, (A.X./1321). *France:* Tinplate, (329). *Latvia:* Rubber, (333). *Netherlands:* Metal, zinc plates, caustic soda, borax, naphthalene, yellow ochre, soap, (C.X./1181). *New Zealand:* Iron, (323). *Peru:* Paints, enamels, (349). *Poland:* Leather, (334). *South Africa:* Cast iron, (A.X.1312). *Spain:* Hardware, (335). *Switzerland:* Petrol, oil, artificial fertilisers, (336). *Uruguay:* Oils, (B.X./1249).

The Production of Soda in the Union of South Africa

There is only one notable occurrence of soda in the Union, namely, that at the Pretoria saltpan. This pan is a crater-like depression some 200 feet below the surrounding country, and about 28 acres in extent. The bed of the pan, from which in the dry season all the liquid evaporates, consists of a black mud containing masses of trona, or solid crude carbonate of soda. The mud, which has been proved by boreholes to be at least 200 feet deep, has the following analysis: Moisture at 120° C., 50 per cent.; Na_2CO_3, 16 per cent.; NaCl, 15 per cent.; $CaCO_3$, 3 per cent.; insoluble matter, 12 per cent., and organic matter, 4 per cent. Recent geological work has proved the pan to be an explosion crater, similar to those which have formed the diamond pipes, and of post-Karoo age. The pan contains three valuable ingredients: (*a*) Saline mud, described above; (*b*) layers of trona or crystallised carbonate of soda; (*c*) saline liquor, containing approximately 10 per cent. soda and 15 per cent. common salt. In 1912 the South African Alkali Co. started to work these deposits at first winning only the trona, as that gave the greatest immediate profit, some 21,000 tons being produced. The trona at the surface then gave out, and the company turned its attention tothe mud. It was, however, found impossible to treat the mud, as the liquor obtained by leaching will not filter, neither will the impurities settle in a reasonable time. In 1919 the original company failed, but fresh capital has been introduced and, under entirely new control, the erection of a plant, designed to produce 8 tons of soda and 16 tons of salt per day, has been completed, and it is hoped will commence work almost immediately. This plant is the outcome of prolonged experiment and shows promise of success.—(*S.A.J.I., July,* 1924.)

Notes on Plants and Products

Chemical Stoneware includes a great variety of products, and as the requirements of users are so diversified, manufacturers usually only stock material that is standardised, such as acid-proof bricks, packing, pipes and fittings. Thus, over 80 per cent. of the chemical stoneware of Maurice A. Knight, of Akron, Ohio, is made to order from customer's specifications. This firm claims that stoneware made to order is not more expensive than products kept in stock, because each piece, whether for stock or to order, is handled and made individually. The catalogue issued by Messrs. Knight gives a good deal of information on the uses and limitations of chemical stoneware, as well as plans and scale drawings of towers and parts of chemical stoneware suitable for absorption, condensation, drying and neutralisation. Material for the construction of towers, tanks, digesters and floors is described, and other subjects such as apparatus for elevating liquids, receivers, jars, jugs, acid-proof cement, kettles, generators and general chemical stoneware are also dealt with. The catalogue contains much information of value to the user of stoneware.

Sulphate of Ammonia is a product which must possess two important qualities in addition to standard composition; it must be both dry and neutral. The plant required to make the highest grade of sulphate of ammonia is described in a pamphlet issued by W. C. Holmes and Co., Ltd., Huddersfield, a firm which has had a long and wide experience in supplying such plants to gasworks and by-products works. Two processes are discussed, the Adam process, used at the Beckton Works of the Gas Light and Coke Co., and the Talk o' th' Hill process, installed at Talke, by the colliery firm of that name. Both processes are designed to ensure a regular output of the highest-grade of ammonium sulphate without undue complication and at the lowest cost. For the working of the processes, the pamphlet will be found an interesting guide, and Messrs. Holmes are prepared to submit designs to suit the requirements of existing plants. The same firm also supplies complete gas-making plant, horizontal rotary washers, and plant for chemical works.

Messrs. James Gordon and Co., Ltd., of Windsor House, Kingsway, London, have recently opened a branch office at 110, Waterloo Street, Glasgow, under the management of Mr. A. D. Burgess. This firm specialises in instruments and appliances for boilers.

West's Gas Improvements Co., Ltd., Manchester, has been awarded one of the contracts for a new gasworks at Prague. Another contract was placed in France, and a third locally.

PUBLICATION RECEIVED

QUALITATIVE CHEMICAL ANALYSIS OF INORGANIC AND ORGANIC SUBSTANCES. By H. W. Schimpf, Ph.D., M.D. Fourth edition, revised by A. I. Cone. Pp. ix. 201. London: Chapman and Hall, Ltd., 1924. Price 8s. 6d.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council of Pure and Applied Chemistry

which consists of Representatives from

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals, and the Royal Agricultural Society.

VOL. 43 NEW SERIES | LONDON, OCTOBER 10, 1924 | No. 41

EDITORIAL

MR. WOOLCOCK'S address as President of the Society of Chemical Industry deals with a topic which is familiar to us all, but needs impressing on us so urgently that practical results will follow. His topic is familiar but his manner of treating it is stamped with his own personality, and some of his arguments possess an originality which arrests our attention. Amongst other points he deals with the desire inherent in many men to attempt tasks for which they are untrained and often unfitted. An editor who has had no editorial training is compelled to blush when his temerity is indicated even in the mild way Mr. Woolcock has chosen. Many men have opportunities provided by happy chance of attempting some new vocation or some new addition to their existing occupations. The novelty of it is its charm; the man who has spent many hours a day for twenty years in drawing wills and conveyances does this work so easily that it loses its inherent interest. The man who analyses heavy chemicals for a similar length of time is ultimately bored by it, though he may do such work better than he can do anything else. The unaccustomed occupation which such men undertake becomes an absorbing interest because of its novelty and corresponding difficulty. Such men as we have been describing become enthusiastic about a new pursuit, and often delude themselves into thinking that their enthusiasm compensates for lack of experience. If they are wise they know that they will always be inferior, in a number of very important respects, to the thoroughly trained man. They can never attain to his judgment on vital issues. If they are not wise they will, even then, do well to read Mr. Woolcock's observations and preserve an outward show of becoming humility. We ourselves hover between these alternatives. The chemist who is brought in contact with the industrialist will only in very exceptional cases become a good man of business. What he can do is to attain an interest in the business problems and an understanding of them even if the solution is beyond his power. The man of business concerned in chemistry will as a rule never be a chemist, but he should cultivate that acquaintance with chemists and chemistry which will make him interested in chemical difficulties. It is not important that these men should know what the other man knows; it is important that each should be interested in the work and knowledge of the other.

* * *

Mr. Woolcock also reminds us that the discoveries of the greatest importance to industry were not made in industrial research but in work undertaken for the extension of our knowledge. It seems to us that this fact is well worth insisting upon, and we are glad that our President has mentioned it. The greatest revolutions in industry and the most striking of new manufactures are due most of all to those who have created and developed the new sciences. We have only to consider how many men and women are employed in the manufacture and use of telephones, motor-cars, gas engines, dyestuffs, artificial silk and crystal sets to be convinced of this. The researches of Darwin, Mendel and Pasteur have been responsible for immense changes in agriculture and medicine. Our modern educational system is inadequate, unless it provides opportunities for the ninety-and-nine to learn their special subjects, and for the one to think and search and so enlarge human knowledge. The same methods do not suit both the ninety-nine and the one. Intensive and rapid pouring of facts from the teacher on to and into the student is a sort of forcible feeding similar to the mechanical contrivances in use for increasing the weight and nutritive properties of the domestic fowl. It is adopted in many schools and universities in several countries. The leisurely and unsystematic procedure of our British older universities provides a suitable environment and a fertile soil for the culture of our future Faradays, Leibigs and Lavoisiers. Even the ninety-and-nine are the better if they have time in which to think, perchance to dream. The more original the teacher, the more original the student. A system of education which aims at

giving the largest amount of knowledge in the shortest space of time is damned.

The Chemical Trade Journal pleasantly chaffs us about a recent editorial, in which we referred to a probable mistranslation of the German word *Leim*, and reminds its numerous readers that a full account of the glue pearls appeared in its columns some weeks before any notice appeared in any other English-printed journal. We are not dejected; should aught annoy us, we refuse to be annoyed! Any disappointment caused by this priority is abundantly compensated by the gracious epithet conferred upon us by the *Chemical Trade Journal* of "stately." For nearly two years we have striven to be stately; we knew that we were dignified, but we were not perfectly sure that we had attained stateliness. It shows what may be done by persistent effort. If only we might receive some lessons in deportment from Lord Curzon, we think our education would soon be complete. As a substitute we have been reading some Deportmental Ditties. In questions of speed in publishing scientific information we suppose that all the weekly journals which deal with chemistry are as speedy as is reasonably possible, and the little back-chat—if that is not too familiar a term for a stately journal—we trust will not ruffle the plumage of any of the editors. None of us attains to the degree in slowness of the old Greek athlete who entered a race with five competitors and came in seventh. If our recollection is correct, he performed this feat by handing his hat and coat to a friend who ran along the track with him, encouraging him to greater speed by frequent and cursory observations. But even the friend, encumbered as he was, got in ahead, or perhaps we should now say, finally obtained priority.

* * *

The psychology of chemists is a topic upon which much might be written. There is an interesting and helpful criticism in last week's *Nature* of the series of pamphlets written for the Wembley Exhibition and this explains some of the difficulties confronting the chemist as propagandist. The reviewer states that the man in the street is usually incapable of abstract thought and that so far as possible things must be presented to him in concrete and predigested form; the language must be simple, concrete and familiar. A little later the reviewer expresses his disappointment that "Chemists and their Work" contains no pithy remarks on the psychology of the chemist. It is quite easy to make such pithy remarks, but whether the man in the street described by the reviewer would have welcomed them or understood them is another question; one requires a considerable acquaintance with chemists to appreciate such philosophical reflections, and the pamphlets were intended for readers who have a very slight acquaintance with chemists or chemistry. It is not to be supposed that the pamphlets referred to are as good as they might be, but they are at any rate a beginning, and such a method of interesting the public in chemistry essential. The writers of the pamphlets and ot writers who will in futuro attempt such a task only learn by practice, and we are not inclined accept the sweeping assertion of the reviewer t the scientific worker is not well fitted to play part of propagandist to the man in the street. agree that the task is difficult, but we are satisi with the success of the first hasty experiment, c fident in the belief that the next time it may even better done. The problem of interesting public in science is too important to be neglected the scientific worker; it is not too difficult for h to attempt. Nearly twenty-four thousand of pamphlets have been sold by Messrs. Benn Brothe and the sale continues.

* * *

In the Report of the Committee of the Privy Coun for Scientific and Industrial Research, Sir Willi McCormick and Sir Frank Heath condemn t too early specialisation of some scientific studer They are convinced that in the last two years school life science must not be allowed to absorb t whole of the student's attention, to the exclusion the humanities and to the detriment of his gene education. We opine that many editors in ma countries will agree with this view. Any branch science is exacting and will absorb as much time can be given to it. The day is not long enough for study, even if supplemented by a considerable pa of the night. Our own belief is that those who are devote their lives to the pursuit of science will ha but little time, after they have attained to years discretion, for learning subjects outside their ov domain. It is therefore essential that while they a still students they shall learn those branches of huma knowledge which are interesting and inspiring b will be of no immediate practical use to them in the professional lives. For the great mass of humani the schools are intended to teach the useful subjec In the case of those who are to be highly educated t school is the one and almost the only opportuni of learning the subjects which will have no immedia effect on their professional work. We are incline to think of all these subjects literature is the mo fascinating. To read the greatest of the world writers in the language they wrote,, is not difficul It is difficult to write elegant Latin verses or goo French prose, but anyone with brains enough t understand tautomerism or thermodynamics coul fairly easily learn to enjoy Horace or Theocritus if h did so at school. The question is, is it worth while We think we never yet met anyone who went so fa as this who did not think it worth while. Will no someone start a Society for the Diffusion of Useles Knowledge? There is a great deal to be said for th old idea of knowledge for its own sake. The world too much with us, late and soon, getting and spendin we lay waste our powers. Books such as De Morgan "Budget of Paradoxes," the "Rejected Addresse and Strachey's "Life of Queen Victoria," should be the subject of a compulsory examination to quali for the F.I.C. or F.C.S. We are willing to help setting the papers.

CHEMISTRY AND INDUSTRY*

BY W. J. U. WOOLCOCK, C.B.E.

Introduction

In the first talk I have to give as President of the Society of Chemical Industry I want to make my position perfectly plain. My predecessors in the chair have been uniformly either distinguished scientists or well-known industrialists—in the case of my immediate predecessor he was both. I am neither. For reasons which seemed good to your Council, and found acceptance among the members of the Society, you have chosen a person whose qualifications are not those which have hitherto been demanded. Whatever the advantages may be, and of these I am in complete ignorance, there are certain disadvantages which are very apparent. I cannot with authority give you to-night a discourse on some abstruse scientific subject or on the industrial application of some outstanding discovery. I can, at best, only offer you some observations of a more or less detached observer in the world of scientific and industrial chemistry. Similar talks have been arranged for me in different parts of the country, and in due course I hope to develop what I conceive to be the fundamental theme which should predominate during my year of office.

We are all members of a unique Society—the Society of Chemical Industry. It is the only Society in this country which represents both the scientific and industrial sides of chemistry. In such a position it is given to members of the Society to exert, if they will, a very beneficial influence, not only on behalf of themselves, nor even on behalf of all those engaged in the practice of the science or the control of the industry, but on the nation at large. It is an influence for good which is only bounded by the enthusiasm and self-sacrifice which they are prepared to put forth.

On future occasions I shall have a good deal to say on what I conceive to be the true policy of the Society in its domestic affairs and in its relations with the numerous other societies, both scientific and industrial, which represent chemistry, pure and applied, in this country.

To-night in this preliminary talk I have chosen as the subject "Chemistry and Industry" because it enables me to range over a number of topics to illustrate what I want to say.

Chemistry and Industry

I postulate first: That for the benefit of the nation there must be the closest working together of the scientist and the industrialist. This I think you will have no difficulty in accepting. On it I want to make one or two observations. The first is that it wants saying at the present time. The rush of modern life is conducive to short memories. Immediately after the war we had no difficulty in realising the interdependence of scientist and industrialist. To-day I think there is a tendency not to insist on this interdependence as much as formerly, and I want to do what I can to-night to emphasise its essential character. It is not difficult to see how, apart from the mere effluxion of time, various causes have tended to weaken the bond. The boom in trade which followed immediately after the war found British chemical industry at its high-water mark. Chemists found employment easily. The industrialists had no difficulty in realising the necessity for a sufficient staff of chemists. The value of research work was realised as never before. Then came the slump, which hit chemical industry in common with all other industries although not as severely as some others. Economies had to be effected in all departments and much work which was not of a character immediately remunerative was stopped. I have no doubt that every chemist in this room feels that the economies which had to be made were begun in the wrong place. It is only human for us to feel that we are the most indispensable of all the units employed in a chemical works. I am prepared to contend that the chemist is most indispensable, but it would be easier to sustain this contention if the relationships between scientists and industrialists were even closer than they are to-day.

Circumstances over which I have had little control have placed me in a position which has given me the opportunity of observing both sides in their native element. Human beings suffer from many common weaknesses. The lack of a proper appreciation, the one of the other, between scientists and industrialists is due to one of these weaknesses. Looking around you will find men with really first class scientific brains who with their gifts for original chemical investigation are a national asset. They appear to be utterly unconscious of this, but would agree with you if you suggested that politics, finance, industry or organisation work is their true forte. The same thing is true of the business man. Those industrialists, who have made good to-day and are likely to retain their positions, have among them men who are quite ready to take on the work of a scientist, or a politician, or a financier, and as for the work of an organiser—there is nothing in it. This weakness for attempting to do the other man's job should be combated.

If the close co-operation which has developed between scientist and industrialist is to be maintained we must each of us have a little better appreciation of the work we are engaged upon and not be too ready to undertake other work in the mistaken idea that, although we have not been trained for it, some spark of genius has made us more competent to undertake it than the man who has spent his life at the job.

There is one other observation I want to make while I am in what I fear you may regard as a censorious mood. I come in contact with a number of our younger men at the period when they have just finished their training and are looking for some work in the industry. In talking to them I am never left in any doubt as to the excellent amount of knowledge thay have obtained. What I am sometimes doubtful about is how far in the course of their training they have been taught to use their

* Address delivered before the Manchester Section, on October 3.

commonsense. The industrialist pays more for commonsense and manipulative skill than he does for mere scientific knowledge of a subject. If we are to bring the two sides more closely together we must not allow the enormous range now covered by the science of chemistry as taught in our Universities and colleges to so occupy time that there is none left for the practice of clear thinking and the exercise of commonsense. A scientific training is not necessarily a handicap in business. Indeed, I find more and more of our best manufacturing firms are taking well-educated young men, often with a University training, and making of them most excellent business men. The experience of one of the best known firms in Manchester confirms this opinion and an interesting case came under my own observation. A young man, a mathematical scholar of Cambridge, came to me about a year ago looking for work. As far as I could see he had no technical qualification whatever, and I told him so. Whereat he rose in his wrath and demanded how I dared penalise him merely because he had a good mathematical brain. I was so impressed by his turning of the tables on me that I found him a very humble subordinate position in the office of a member of my association. I anticipated he would not survive the drudgery for three months. I am very glad to say that he is still there and if he continues on his present lines will make a very good position for himself.

But let us look on the other side of the picture. I think the industrialist has been very much responsible for the long time it has taken to eradicate the idea from some minds that there are two kinds of science—pure and applied. And yet how many years ago was it when Huxley said that "What people call applied science is nothing but the application of pure science to particular classes of problems." The chemical manufacturer is apt to consider that the applied science which he practices differs in some way or other from the pure science of the chemist. This misunderstanding militates against the co-operation for which I am pleading to-night.

The industrialist, particularly when times are bad, is apt to consider any research which is not directed to the solution of some urgent problem which has arisen in his works as a waste of time. I have read somewhere that "discoveries in applied science may produce a reformation, but those in pure science lead to revolutions." The industrialist may reform his process, but if he goes a step further he may have such a discovery made in his laboratories as will revolutionise his whole business. In the intense world struggle for business with which we are face to face, it is the revolutionary discovery to which we must look for help. I think we need reminding that while some discoveries have been born out of the necessity of finding an answer to a problem, far greater in number and subsequent importance are those which have been made in researches undertaken for the extension of our knowledge.

But great advances in bringing together the scientist and the industrialist have been made in recent years. The formation of the Association of British Chemical Manufacturers has been of use in this connexion. It has brought the manufacturers into such close contact that it has tended to level up the ideals of the less progressive to those of the more enlightened. The gain to the manufacturers has been obvious, but there has been an equal gain to the scientists, not perhaps quite so obvious. It is a threefold gain; first, the progress of the industry is essential if employment is to be found for all those who are being trained as chemists. Secondly, the success of co-operation among the units of the industry tends to foster co-operation between the different branches—technical and non-technical—in the same firm. And, thirdly, the levelling-up of ideals due to co-operation among the manufacturers makes for better conditions under which the chemist works.

The joint meetings of local branches of the various Societies have assembled together the research chemists in University Laboratories and Works Laboratories, the chemists from chemical factories, and the industrialists who are members of the Society of Chemical Industry. This, to my way of thinking, is all to the good. In the present stage of fierce international competition there is no room for petty differences between Societies of any nation, but it is the time for a uniting together of all the National Societies.

I must leave for another occasion the part which I believe the scheme for a Chemistry House must play. Suffice it to say that I believe it to be an essential step to further co-operation between the Societies.

There has, however, been one other factor which has overshadowed all others this year in stimulating co-operation between science and industry. I refer to the British Empire Exhibition. In the early days of preparation for the Exhibition no provision was made for scientific displays. It was a question of money, and neither the Government nor the Exhibition Authorities seemed willing to provide it. It is to the everlasting credit of British Chemical Science and Industry that at this point the decision was taken that Chemistry should be represented even if no other science were there, and that Chemistry would finance its own exhibit. I like to think that this decision had considerable influence on the Government, which ultimately, through the Department of Overseas Trade, provided funds to enable other sciences to be shown at the Exhibition.

It was in January, 1923, that the Joint Scientific Chemistry Committee was appointed with Dr. Levinstein as its Chairman. The Committee was extremely fortunate in securing his services. The presence in the Chair of a man who combined scientific knowledge with industrial experience was invaluable, and he gave freely, both time and money, to make the project a great success. As the work of the Committee progressed, the Government relented and placed at the disposal of the Royal Society a sum of money to be spent on a scientific exhibit and provided a home for it in the Government Pavilion. Here, you will see, were great possibilities for all sorts of friction, overlapping of work and clashing of interests. None of these things happened. The representatives of the Royal Society, the premier scientific society of the world, worked together not

only with the representatives of other scientific societies, but of industrial associations as well. You will pardon me, I am sure, if I publicly acknowledge the unique compliment which was paid me as a representative of industry by appointing me a member of the Exhibition Committee of the Royal Society. Now, let us look at the results that flowed from this co-operation. The Royal Society found itself with a sum of money and a home for its exhibit provided by the Government. The Joint Committee of the other societies and associations had a similar sum at its disposal provided by these other societies and associations. The next step was to prevent overlapping. The Joint Committee's arrangements were well forward for the Chemistry Exhibit. The Royal Society therefore left this branch of science entirely to the Joint Committee, and concentrated all its limited financial resources on Physical and Biological Sciences. The only place where there was danger of overlapping was the borderland between physics and chemistry, and a few conversations on the question were sufficient to settle this point. I would like to add that the Royal Society went so far as actually to obtain for the Joint Committee some of the specimens you will find in the Chemical Hall. The contribution of the Manchester Literary and Philosophical Society, for example, consisting of Dalton's original diagrams, was set off by the work of Sir William Bragg and Prof. W. L. Bragg, accomplished 120 years later and shown side by side with them.

I believe the credit for the easy settlement of the borderland problem should be given to Sir William Bragg, who, in the course of one of our meetings, proposed the formula: "The outside of the atom to the Joint Committee: the inside to the Royal Society." In such familiar terms do these great scientists treat these, to us, infinitely little bodies!!!

Now, let us look at the even closer co-operation which prevailed among the societies and associations represented on the Joint Scientific Chemistry Committee. Here you had our own Society, the Chemical, the Institute of Chemistry, the Association of British Chemical Manufacturers, the Society of Petroleum Technologists, the Society of Dyers and Colourists, the Institution of Chemical Engineers, and the Pharmaceutical Society, all represented, each contributing to a common fund, and all striving together for a common purpose. What was the result? There was presented to the whole world a wonderful picture in a very beautiful setting of the present state of British Chemical Industry. I think the most impressive feature was the demonstration of the way in which each tiny portion fitted into the general scheme and the completeness of the range of products shown. But it went further than this. We expected a large number of intelligent foreign visitors to visit the Exhibit, and their numbers far exceeded our most optimistic estimates. We, therefore, set ourselves to answer an anticipated question, which we were certain to be asked: Whether this display merely showed a Chemical Industry which was a war product; whether, in fact, to put it another way, we were being typically British and developing an industry merely to hand it over to someone else. The answer was in the Scientific Section. Here was indicated some of the research work which had been going on. Here was the guarantee that, as your Chairman used to say, the stream of invention was flowing not sluggishly but freely in this country. The co-operation of the scientist and the industrialist had demonstrated that British Chemical Industry in all its present-day completeness had come to stay.

We went further. We realised that a large number of scientists scattered over the face of the globe would be unable to visit the Scientific Exhibit, and that even those who could visit it would want a reminder of what they had seen. So "Chemistry in the Twentieth Century" was produced, edited by your ex-President, Dr. Armstrong, and the book has had a remarkable sale.

One other point of view was considered, and again your Society must be given the credit. There is a large public which is interested in science. It is well represented by the numbers of middle-aged men who somewhat diffidently visited the Scientific Exhibit. If one got into conversation with them you found it was a case of: "Did a little chemistry when I was a boy; still like to read about it." For this class of visitor there were prepared a series of eight pamphlets on various branches of Chemical Industry, written in a popular style and edited by Dr. Miall, the editor of *Chemistry and Industry*. Thousands of these pamphlets were sold at the Exhibition, and I have no doubt did an immense amount of good.

I think I have said sufficient to-night to convince you that the results already obtained by the closer co-operation of those engaged in Chemical Science and Chemical Industry have amply justified the efforts which have been made. I believe it to be the settled policy of your Council to continue these efforts. The branches of the Society are on the threshold of a new winter session, and the Council is anxious that in every branch it shall find support for this movement.

I am confident we shall not look in vain to Manchester.

METALLURGY AND MINING IN CANADA

The Victoria Syndicate, Ltd., has been incorporated and is sponsored in Canada by the Mond Nickel Co. It is reported to be a combination of the Central Mining and Investments Corporation and the Mond interests. It has commenced an active investigation of the gold and silver districts of northern Ontario and north-west Quebec. Percy E. Hopkins, formerly of the Mines Department of Ontario Government, and now Chief Geologist for the Mond Nickel Co., is making a survey of the territory. The Mond Nickel Co. has blown in another furnace, which will bring the production up to the highest war-time peak. This company is now the largest producer of nickel in Ontario.

THE EARLY HISTORY OF ANTIMONY

By HARRY HYMAN, Ph.D.

The part played by antimony in the early history of chemistry is generally overlooked, its claims to an all-important position being overshadowed by its great rival, gold. There is a considerable amount of evidence, however, that antimony and its compounds must have proved of fascinating interest to many of the early chemists, and it is indeed probable that the study of this metal led to more developments in the early history of the science than did that of the precious metal. This fascination became in some cases so absorbing that entire lifetimes were devoted to its study, and the specialisation which we are inclined to attribute to the economic conditions of the present era was in force several centuries ago. The result of this intensive study was the publication of several books dealing entirely with this metal, all of which remain as landmarks in the steady progress of the science.

From our present knowledge of the chemistry of antimony it is not surprising that so many devotees worshipped at its shrine. It is capable of forming a large number of compounds and is very responsive to all the chemical processes known in the past few centuries. Many of its compounds are of medicinal value and can also be employed in the arts. In the case of gold, fewer compounds are produced, whilst its costliness and scarcity prevent their application for general purposes. If it were not for the belief that some compound of gold would yield the *elixir vitæ*, the substance that would prolong life indefinitely, the chemistry of this substance would not have been so assiduously pursued.

As early as the sixteenth century Du Chesne wrote: "There are six hundred very good properties in antimony," and in the following century Webster in his "Metallographia" says "for there is scarcely any one mineral that is more largely treated of than antimony." The "chemical dispensatories" of the period contain innumerable descriptions for the preparations of its various compounds, its oils, balsams, infusions, tinctures, flowers, and if it cured all the illnesses and diseases for which claims were made, then it had the just right to be termed the universal panacea. Its compounds were used both internally and externally, for mild complaints or critical conditions, for toning the system, cleansing the blood, as a cure for fevers, wounds, skin diseases, smallpox and every complaint imaginable.

One of the earliest books on the subject appeared in Leipzig in 1604, "The Mysterious Gem of Antimony," by Alexander Von Suchten. This was a complete treatise on the subject, consisting of over five hundred pages and provided with an index. It was divided into two sections, the first dealing with its compounds and their medicinal properties, and the second with the extraction of the metal. The book was an important one at the time and went through many editions. Von Suchten flourished in the latter half of the sixteenth century and lived at Danzig. He possessed the double qualifications of chemist and poet. An English translation of his work by Dr. Cable was published with the following title page: "Alex. Von Suchten's Of the Secrets of Antimony: in Two Treatises. Translated out of High-Dutch by D. C. a Person of Gr… Skill in Chymistry. To which is added B. Vale… gain Salt of Antimony, with its Use. London, P… It and are to be sold by Moses Pitt at the Whitustry in Little Britain, 1670." those

Twenty years later, that is in 1624, there …ly, the also in Leipzig, another treatise on th… of the namely, "The Triumphal Chariot of …tween the by Basil Valentine. This was also a c…technical— treatise and extended to six hundre…lling-up of went through many editions and wa…ufacturers into several languages. An English trans…hemist Richard Russell appeared in 1678 and a La… version, with a commentary by Theodore Kerckringius, was issued at Amsterdam in 1685. An English translation of the latter work with a biographical preface was made in 1803 by A. E. Waite.

Very little is known about the actual life of Valentine. He is alleged to have been a Benedictine monk living in South Germany during the fifteenth century, but modern historians are inclined to the view that such a personage never existed. It is more than probable that the various works attributed to him, including the "Triumphal Chariot," were written by his editor, John Thölde, who was born in the latter half of the sixteenth century: but why they should have been issued under another name is a mystery which has not yet been satisfactorily explained. The author, whoever he was, must have been an experimenter of more than average ability, as many of his writings contain first descriptions of important chemical reactions and compounds. Complete instructions are given for the separation of the metal from its ores, and for the preparation of various compounds, many of which were advocated for medicinal purposes.

In 1660 Guerner Rolfinck published at Jena a "Chemical Dissertation on Antimony." This was issued in pamphlet form and contained an account of a debate held in the medical lecture room of the University. Rolfinck was one of the most learned men of his day. Born in Hamburg in 1599, he received his education at the universities of Leyden, Oxford, Paris and Padua, and subsequently became professor of chemistry at Jena. According to Stahl, he played a great part in bringing the science of chemistry into shape and laying a foundation stone on which many subsequently built. Besides possessing a profound knowledge of languages, philosophy, science and medicine, he was a keen anatomist and was bitterly disappointed when any criminal escaped him. One unfortunate person on being brought to the gallows requested that he might not be "rolfincked" after his death. Rolfinck, on hearing this, exclaimed, "Ha! you scoundrel, you are too 'putrid' for me, else I would have rolfincked you with my scalpel." The phrase remained for a considerable time a popular one as an equivalent to dissect.

Thirty years later, *i.e.*, in 1690, a useful German booklet on the metal was written by John Bernhard Horn, and about the end of the century a Frenchman.

Nicolas Lemery, issued his "New Curious Chemical Secrets of Antimony," a well-informed book of close on six hundred pages. Lemery was one of the most ledg[illegible]ous chemists of his day, and was noted for the a repr[illegible] of his writings, in which all traces of mysti- membe[illegible]re removed. He was trained as an apothecary Society[illegible]r travelling for several years settled down in from th[illegible]here he gave practical demonstrations and itself with[illegible] His fame spread and students from all provided by[illegible]rope flocked to attend his classes; from of the other [illegible]e no fewer than fifty students in one sum at its dis[illegible] hear him. Owing to religious difficul- and associati[illegible]o England for a short period, and after lapping. T[illegible] France led a rather unsettled life. He well f[illegible]715. He wrote a valuable treatise on [illegible]mistry which was published at Paris in 1675, and went through eleven editions. It was translated into Latin, German, English and Spanish.

Almost a century later, in 1791, a book was published in this country by George Pearson, M.D., F.R.S., under the title, "Experiments and Observations to Investigate the Composition of James's Powder," the history of which is largely associated with this element. James's Powder was a favourite nostrum of the eighteenth century, and consisted chiefly of oxide of antimony and phosphate of lime. The inventor was Dr. Robert James, grandfather of G. P. R. James, the novelist, and an intimate friend of many of the famous literary men of that century. He formed a close acquaintance with Dr. Goldsmith through the latter's publisher, a Mr. John Newbery, who, besides conducting a bookseller's business, also carried on a large trade in the sale of patent medicines. Newbery arranged a contract with James to sell his fever powder and pills, the publishing business of the former affording ample scope for the advertisement of these products. The powder was claimed to be a valuable remedy for "Fevers, Small Pox, Measles, Pleurisies, Quinsies, Acute Rheumatism, Colds and Inflammatory Disorders." Goldsmith himself was a frequent user of nostrums, firmly refusing the services of qualified physicians. He even made it one of his hobbies to prescribe for others. "I do not practice," he once said: "I make it a rule to prescribe only for my friends." "Pray, dear Doctor," said Beauclerk, "alter your rule, and prescribe only for your enemies." Contrary to this advice, Goldsmith continued his practice, and when seriously ill sent his servant to Newbery's shop for a dose of the powder. The remedy aggravated the malady, and although physicians were called in he died shortly afterwards. Soon after his death, Hawes, his surgeon-apothecary, formed the opinion that the powder had had no beneficent effect on his patient, and published a trenchant pamphlet entitled "An Account of the late Dr. Goldsmith's Illness as far as relates to the exhibition of Dr. James's Powders," 1774. This was vigorously replied to by Newbery's son, but the controversy appeared to have had little effect on the sale of the nostrum. During the illness of George III in 1778, it was recommended for that monarch, and the King himself prescribed it for Princess Elizabeth.

Horace Walpole, though inclined to be rather cynical, had much to say in favour of Dr. James's remedies. In 1764 he thus wrote to Sir Horace Mann: "James's Powder is my panacea: that is, it always shall be, for thank God! I am not apt to have occasion for medicines: but I have such faith in this powder, that I believe I should take it if the house was on fire. Have you ever had any of it? or shall I send you a parcel of papers?" Thomas Gray and William Cowper also put their faith in the powder, and Henry Fielding and Samuel Johnson were among others who offered words of praise. The last-named showed his

Frontispiece of the Latin version of Basil Valentine's "Triumphant Chariot of Antimony," Amsterdam, 1685. In the Library of the Royal Technical College, Glasgow. James Young Collection.
[Actual size.]

appreciation by writing a dedicatory preface in his best literary style for James's work, a "Medical Dictionary, with a History of Drugs" (3 vols., 1743).

Enough has been written to show the influence which a compound of antimony exerted on the literary vagaries of the eighteenth century. That this element played an important part in the development of chemistry during the sixteenth and seventeenth centuries there can be no shadow of doubt, and at the present day it continues to uphold the worthy traditions of a glorious past.

FORTHCOMING EVENTS

Oct. 10. UNIVERSITY OF LONDON, UNIVERSITY COLLEGE, Gower Street, W.C. 1, at 5.30 p.m. "Water Supply and its Purification," by Prof. S. L. Rushkovitch. Also on October 17, 24, and 31.

Oct. 11. NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS, Lecture Theatre of the Institute, Newcastle-on-Tyne, 2 p.m. (1) "Safety Lamps giving warning of Gas," by Dr. W. M. Thornton. (2) "The Heat due to Strata Movement and its Effect on Certain Coal-Seams," by Prof. H. Briggs, A. L. S. Owen and J. Wilson. (3) "The Washing of Fine Coal by the Froth-Flotation and Concentrating-Table Processes at Oughterside Colliery, Cumberland," by J. G. Scoular and B. Dunglinson.

Oct. 11. SOCIETY OF CHEMICAL INDUSTRY, *Nottingham Section.* Annual Dinner, at the Flying Horse Hotel, Poultry, Nottingham, at 7 for 7.30 p.m. Tickets 5s. each, exclusive of wine.

Oct. 13. INSTITUTE OF METALS, *Scottish Section*, 39, Elmbank Crescent, Glasgow, at 7.30 p.m. "Brass Foundry Costing," by J. Stirling.

Oct. 13. THE INSTITUTE OF BREWING, *London Section*, Engineers' Club, 39, Coventry Street, W.C., at 7.30 p.m. Discussion on "The Characteristics and Peculiarities of the Season's Malt."

Oct. 15. ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell Square, London, W.C. 1, at 4 p.m. "Physique in Relation to National Efficiency," by Sir W. Milligan, M.D.

Oct. 15. INSTITUTE OF CHEMISTRY, *London Section*, 30, Russell Square, London, W.C. 1, at 8 p.m. A number of Fellows and Associates from abroad will speak of the position of chemistry in their respective countries.

Oct. 16. INSTITUTION OF THE RUBBER INDUSTRY, *Manchester Section*, 16, St. Mary's Parsonage, Manchester, at 7.30 p.m. "Some Problems in the Rubber Industry," by H. Standring.

Oct. 16. THE INSTITUTION OF MINING AND METALLURGY, Geological Society's Rooms, Burlington House, Piccadilly, London, at 5.30, "Hygrometry for Deep Mines," by J. S. Jones.

Oct. 16 and 17. UNIVERSITY OF LONDON, King's College, Strand, London, W.C. 2, at 5.30. (1) "Organic Radicals"; (2) "Theory of Oxidation Processes," by Prof. Dr. H. Wieland.

Oct. 16. THE CHEMICAL SOCIETY, Burlington House, Piccadilly, London, W. 1, at 8 p.m. (1) "The Influence of Catalysts on Carbonisation," by R. Lessing and A. Banks. (2) "The Photosensitive Formation of Water from its Elements in the Presence of Chlorine," by R. G. W. Norrish and E. K. Rideal. (3) "Investigations on the Dependence of Rotatory Power on Chemical Constitution. Part XXIV. Further Experiments on the Walden Inversion," by J. Kenyon, H. Phillips, and H. G. Turley. (4) "The Directive Influence of Substituents in the Glyoxaline Nucleus on Substitution in the Benzene Nucleus of Phenylglyoxalines—the nitration of 2-phenylglyoxaline and its carboxylic acids," by F. L. Pyman and E. Stanley.

SOCIETY OF CHEMICAL INDUSTRY

CHEMICAL INDUSTRY DINNER

The Autumn Dinner, which will be under the auspices of the Society of Chemical Industry and the Chemical Industry Club, will be held in the Edward VII Rooms of the Hotel Victoria, Northumberland Avenue, London, W.C. 2, on Friday, November 14, at 7 for 7.30 p.m., and will be presided over by Mr. W. J. U. Woolcock, C.B.E., President of the Society.

A circular letter with further particulars and a form of application for tickets has been sent out to the members.

BACK NUMBERS OF JOURNAL

The General Secretary will be glad to hear from Members or Subscribers who have copies of the *Journal* for January 5, 1923, or January 4, 1924, that they are willing to dispose of to the Society.

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

The price of Volume VIII (1923) to members of the Society is 7s. 6d., and to non-members 12s. 6d., post free in each case.

Fellows of the Chemical Society have the privilege of purchasing the volume at the price of 10s. post free.

A set of Volumes II to VIII inclusive can be purchased by a member of the Society at the price of £2 2s. 6d., and by a non-member at the price of £3 15s., post free in each case.

CHEMICAL SOCIETY'S ANNUAL REPORTS

The Council of the Chemical Society has decided to increase the price of future issues of the Annual Reports on the Progress of Chemistry, and the volume for 1924 (XXI) which will be issued next year will be sold to the public at 10s. 6d., plus postage. To members of the Society of Chemical Industry will be given the privilege of purchasing the volume at 9s., post free. Orders, accompanied by the appropriate remittance, should be sent to the Assistant Secretary, Chemical Society, Burlington House, London, W. 1, before the end of the present year.

DEATHS

Allen, John (Original Member), of Phœnix Chemical Works, Upper North Street, Poplar, London, E. 14. On August 30, 1924.

Bamber, H. Kelway G. (elected 1894), of Stone Castle, Greenhithe, Kent. Cement Works Manager. Killed in motor accident on September 20, 1924.

Brown, E. Hilton (elected 1890), of 156, Artillery Mansions, Victoria Street, London, S.W. 1. Analytical Chemist. On September 11, 1924.

Hehner, Otto (Original Member), Panplatts, Pan Station P.O., Transvaal, South Africa. Consulting Chemist. On September 9, 1924.

SOCIETY OF PUBLIC ANALYSTS

Five papers were read at the meeting held in the Chemical Society's Rooms on October 1, Mr. G. Rudd Thompson in the chair.

A paper on "The Determination of Coconut Oil and Butter Fat in Margarine," by G. D. Elsdon, B.Sc., and Percy Smith, discussed the methods suggested for calculating the percentages of butter and coconut oil present in margarine from a consideration of the Reichert-Polenske-Kirschner process. The authors attempt to show that there is some uncertainty in these calculations and, from analyses of a large number of mixtures of known composition, they attempt to introduce some improvement. The Blichfeldt process is discussed, and the opinion given that this has no particular advantage over the processes now generally in use—a modification of this process suggested by the authors is found to be inferior to the Kirschner process though somewhat more rapid.

"A Preliminary Note on the Composition of the Fat of Goat's Butter" was presented by F. Knowles and J. C. Urquhart, B.Sc. Owing to the increasing number of herds of goats in the country, and consequent increase in sale of butter obtained from this source, the authors raise the important point whether or not it is legal for this product to be sold as "butter." Analyses are given of samples of the fat of goat's butters where the usual conventional methods were employed. Particular attention is directed to the Polenske value, which varied from 4·9 to 8·7, and which, if interpreted in the light of the usual standards for cow's butter, would erroneously be assumed to indicate adulteration.

"The Quantitative Estimation of the Degree of Hydrolysis of Gallotannin by Tannase" was discussed by Miss W. N. Nicholson, B.Sc., and D. Rhind, B.Sc. Tannase disintegrates gallotannin, gallic acid being produced. The activity of tannase can therefore be measured by estimating the unchanged gallotannin. Such a method has been devised by Rhind and Smith (*Biochem. J.*, 1922, **16**, 1). It can also, however, be measured by estimating the amount of gallic acid produced by the enzyme. A method for the estimation of gallic acid produced by tannase has been described by Freudenberg and Vollbrecht (*Z. physiol. Chemie*, 1921, **116**, 277). In this method the gallic acid formed by the action of tannase on gallotannin or methyl gallate is estimated by titration with sodium hydroxide, litmus paper being used as an indicator. It is assumed by Freudenberg and Vollbrecht that, under the condition chosen by them, only the carboxyl group in the gallic acid reacts with sodium hydroxide. This method has now been tested and has been found not to be reliable. Concordant results, however, have been obtained by using a slight modification of Mitchell's colorimetric method for the estimation of small quantities of gallic acid (*Analyst*, 1923, **48**, 2). This method has been in constant use during the last eighteen months in the work on tannase and has been found to give good results.

In considering "The Pemborton-Neumann Method for the Estimation of Phosphorus," Miss M. B. Richards and W. Godden, B.Sc., A.R.C.S., show that the chief sources of error in this estimation are: (1) absorption of carbon dioxide by the alkali used to dissolve the ammonium phosphomolybdate precipitate; and (2) the use of a wrong factor. Errors due to (1) may be eliminated by boiling with excess of acid before the final titration. (2) Instead of Neumann's factor 0·001268, the authors use the factor 0·001365, believing that the formula of the precipitate obtained by their procedure is $(NH_4)_3PO_4, 12\,MoO_3$. The use of this new factor, combined with the method of precipitation and washing detailed in the paper, gives results in close agreement with those obtained by gravimetric analysis.

Mr. W. S. Shaw, M.Sc., read a paper on "The Application of 'Formol Titration' to the Kjeldahl Method of Estimating Nitrogen," in which he said that, in order to eliminate distillation the formol titration method was adapted to the estimation of nitrogen after the usual digestion with satisfactory results. The colourless solution is diluted and boiled to expel sulphur dioxide, neutralised and left slightly acid, and made up to 250 c.c. Twenty-five c.c. of the solution is rendered alkaline with normal sodium hydroxide solution, re-acidified with 0·1 normal sulphuric acid, boiled, cooled rapidly, and titrated with 0·1 normal sodium hydroxide solution with phenolphthalein as indicator. Five c.c. of formaldehyde solution (commercial formalin of determined acidity) is added, the mixture allowed to stand for a few minutes, and the acidity titrated with 0·1 or 0·2 normal sodium hydroxide solution. The acidity due to the formaldehyde solution is corrected for, and the nitrogen calculated.

METALLURGICAL AND MINING NOTES FROM CANADA

The British Empire Steel Corporation has received an order from Germany, for 100,000 t. of iron ore which will be shipped from the company's mine at Wabana, Bell Island, this year.

The value of the mineral production of British Columbia for the year 1923 was $41,304,320. This is $6,145,477 greater monetary value than the output of 1922, an increase of 17·5 per cent.

Palladium is being produced at the Saltchuck Mine, B.C., and the concentrates shipped to the refinery at Irvington, N.J.

The annual financial statement of the McIntyre Porcupine Mines Ltd., shows that 360,140 t. of ore were treated of an average value of $9·69, and containing in all 157,702, fine oz. gold and 27,550 oz. of silver. The annual dividend, which has been 15 per cent., is to be increased to 20 per cent.

The Wright-Hargreaves Mining Co., is increasing its milling capacity from 150 to over 400 t. of gold ore daily.

The Hollinger Co., which has been handling 6500 t. of ore per diem, expects to have a throughput of 8000 t. within two months. When this is accomplished it will be the largest gold producing mine in the world.

REVIEWS

The Theory and Application of Colloidal Behaviour. Edited by R. H. Bogue. Vol. I.—Theory. Pp. xxx+444. Vol. II.—Applications. Pp. xxvii+445-829. New York: The McGraw-Hill Book Co., 1924. Price £2.

This work consists of a series of essays on various aspects of the subject by a number of authors. The editor states in the preface that it is an attempt to meet the need for a comprehensive treatise on the colloidal state and its more general applications. Unfortunately the book itself falls short of the promise of the preface.

The treatment of theoretical aspects in the first volume is decidedly scrappy. The editor hails the Donnan equilibrium (attributed to Prof. "Frank" G. Donnan) as a general factor in colloidal behaviour, and the first two papers, by J. A. Wilson and the late Dr. J. Loeb, are mainly concerned with the properties of proteins seen in the light of this theory. Other authors in this volume either ignore the theory altogether or point out its very limited applications. H. B. Weiser, who gives a good summary of what is known so far of the properties of jellies, points out that, however useful the Loeb-Wilson theory may be in explaining the swelling of gelatin, it is obviously inapplicable to the parallel phenomenon of the swelling of rubber in benzene.

There is a good deal of overlapping in the papers in this volume. Prof. Freundlich writes with his usual clarity on the sensitisation of suspensoids by minute quantities of emulsoids, but the same matter is dealt with more briefly by A. W. Thomas in a section on the mutual reactions of colloids, a portion of the subject also partly covered by J. H. Northrop in a chapter on colloidal suspensions. There is also a tendency, particularly noticeable in the two latter papers, to emphasise the work of the authors themselves, which, however desirable it may be on other occasions, is scarcely what is looked for in a comprehensive treatise.

There are several remarkable omissions in the work as a whole, and such fundamental matters as dialysis, the ultramicroscope and the Tyndall cone are not even mentioned in the index. No attempt is made to give the reader any appreciation of the specialised technique of the subject except in isolated cases. The division of the subject matter into "theory" and "applications" seems to have been made with a view to the equal size of the volumes, and papers on the body fluids, enzymes and catalysis are included under "theory."

The second volume is much more satisfactory in covering the wide field of the applications of colloid chemistry, and indicates both the results so far obtained and the directions in which further work is required. The seventeen papers summarise the colloidal features presented by minerals, soils, metals, fuels, smokes, silica, cereals, fruit jellies, cellulose, rubber, leather, gelatin, and casein. Photography, sanitation and diet are also discussed from the colloidal point of view. The matter in a few of these sections is not otherwise easily available, and the technical chemist will find this volume much more useful and interesting than many parts of the first book.

The volumes are well produced, but the reading of proofs might have been more careful; the editor suffers from an inability to spell proper names in the usual way, and an eminent British chemist is referred to as Föerster.

P. C. L. Thorne

Carbid und Acetylen, als Ausgangsmaterial für Produkte der Chemischen Industrie. By Prof. Dr. J. H. Vogel and Dr. Ing. Armin Schulze. Pp. 130. Leipzig: Otto Spamer, 1924. Price, paper, 5 g.mk., bound, 6 g.mk.

As indicated in the preface, the first 100 pages of this book, dealing with the physical and chemical properties of acetylene and the use of acetylene as a raw material for the chemical industry, are practically identical with the corresponding sections of "Das Acetylen," by Prof. J. H. Vogel (Otto Spamer, 1923), very slightly amended and amplified in places. These are followed by a new section on the cyanamide industry (10 pages) and by name and subject indices. The sections on the physical and chemical properties of acetylene are an excellent summary of what is known on the subject with very full references to the literature. On pp. 9 to 11, three divergent sets of figures are given without correction for the limiting explosive compositions of acetylene-air mixtures.

The section on the use of acetylene as a raw material in chemical industry deals with the manufacture and properties of chlorinated products, carbon black, graphite, hydrogen, acetaldehyde, acetic acid, acetone, alcohol and their derivatives, also of artificial rubber, varnishes and allied products. This section appears to be an excellent account of German industrial methods. The authors state on p. 97 that they have mainly confined themselves to German and Swiss methods. The book would be more valuable had it included some account of industrial developments elsewhere.

On p. 103 the authors refer to the manufacture of synthetic acetic acid and so forth at "a works at the Shawinigan Falls in Quebec, Canada."

The section on cyanamide manufacture is too short to allow of adequate treatment of the subject, and here again attention is almost entirely confined to German methods and developments.

In spite of the defects indicated the book can be recommended to those who do not possess a copy of the 1923 edition of "Das Acetylen."

Ernest Fyleman

BRITISH PORTLAND CEMENT MANUFACTURERS

The Hon. F. C. Stanley and Messrs. A. White, A. Brooks, and G. E. V. Cranage have resigned from the board. The new directors are Lord Meston, Sir J. A. Horne, Mr. W. J. Firth and Mr. P. J. Pybus. An interim dividend on the ordinary shares of 5 per cent. less tax (the same as the interim dividend last year) has been declared.

REPORTS

Report of the Committee of the Privy Council for Scientific and Industrial Research for the Year 1923–24. Pp. 139. Cmd. 2223. H.M. Stationery Office, 1924. Price 3s.

The expenditure of the Department of Scientific and Industrial Research for the financial year 1923-24 was £515,382, including £33,367 expended on headquarters administration and made up of £274,297 from the Exchequer, £42,761 from the interest and £103,187 from the capital of the Million Fund, and £85,251 from fees for tests and special investigations. The balance of £9886 was met from the grant in aid of £39,500 voted in 1921-22 for increasing developments of the Department's researches. The balance of £29,614 has been carried forward and supplemented by £15,000 voted in the estimates for 1924–25. The estimated net expenditure for 1924–25 is £328,281.

During the year 291 grants were made to research workers and students in training at a cost of £45,303. Other expenditure was as follows: National Physical Laboratory, £162,290, a large part of which was met by fees and other payments; the Fuel Research Board, £46,319, (receipts £3978); the Geological Survey, £58,115; Building Research Board, £8960; grants to 23 research associations, £103,187. The balance of the Million Fund at March 31, 1924, was £618,318. Further grants have been promised to the Research associations for the photographic, woollen and worsted, cotton, scientific instruments, and linen industries, and grants have been offered to others. A research association for the sugar industry is being formed.

In the Report of the Advisory Council it is stated that reviews of nine research associations have furnished evidence of the progress of co-operative research. For the greater part, the research associations are stated to be fulfilling the hopes held at the beginning of the scheme, which as a whole has justified its inception. Many of the investigations have been planned to expose the basic scientific facts underlying technical operations, and team work is being encouraged in the scientific staffs. After careful consideration, from a broad standpoint, of consultative work carried out by the associations, it is advised that the extent of such work should be watched carefully, and should be strictly limited.

The committees report that the associations have been administrated economically, and consider that further aid to associations should take the form of block grants diminishing annually in amount and so graduated as to make the ultimate change over to complete independence a relatively easy matter. Thus, the British Portland Cement Association has carried out valuable scientific work and the industry is receiving subscriptions to carry on without further State assistance. Further assistance is needed for the research association for the woollen and worsted industry, and extra grants will probably be given to the cotton and linen research associations. Special consideration has been given to the British Scientific Instruments Research Association, which is stated to have achieved valuable practical results. The improvement effected by the Glass Research Association in the general outlook and technique of the industry is appreciated, but the committee was not so favourably impressed with the scientific results achieved. As the present financial position of the industry affords no prospect that funds will be found to continue the association, steps will be considered to provide for research in this industry. The facilities at the disposal of the Fuel Research Board are to be increased to test promising plant or processes for the low-temperature carbonisation of coal, and to press forward the physical and chemical survey of the national coal resources. The Chemical Research Board has now been provided with a chemical laboratory close to the National Physical Laboratory, and it has been decided that the grant to the Institute of Metals for the study of corrosion of metals should cease and that this work should be carried on by the Chemistry Research Board under a committee presided over by Prof. H. C. H. Carpenter, Dr. D. G. Bengough being in direct charge of the investigations.

In discussing grants to research workers and students in training, the Report states that the standard of the work done by the students has been definitely raised, and observes in relation to the reports they have sent in, that bad style and bad work frequently go hand in hand. The defect is attributed to too early specialisation, and the Advisory Council considers that in the last two years of school life science should not be allowed to absorb the whole of the student's attention to the exclusion of the humanities and the detriment of his general education. When the student has graduated, and is serving his apprenticeship to research, he should be encouraged to devote attention as part of his training to the historical and cultural aspects of his subjects. Students specialising in chemistry still preponderate, but there is a small increase in the number of those specialising in the biological sciences. The Council notes with approval a tendency for chemistry students to pay more attention to topics with a biological training.

Arrangements have been made with the Royal Institution for the continuance of Sir William Bragg's researches on the X-ray analysis of crystals. The proposals for the international protection of scientific property put forward by Senator Ruffini were considered, and it was concluded that not only were the proposals impracticable, but that if they were put into force they would have an unfortunate influence on the outlook of workers in pure science.

The National Physical Laboratory is investigating the proposal to adopt a wavelength of light as a standard of length, and has carried out important work on the maintenance of standards, alloys, methods of producing pure metals, minor metals, and the structure of metals and alloys.

Good progress has been made with the survey of the national coal resources by the Fuel Research Board, and it is hoped shortly to publish recommendations on sampling. The work on carbonisation has been continued, and interesting results have been obtained with the Lessing process, applied to separate low-temperature tar into light spirit, heavy oils and

pitch. Other work of the Board bears on internal combustion engines, boiler tests (carbon dioxide recorders), the hydrogenation of oils and coals, and domestic heating, a report being in preparation on the last-named subject. The research work on the direct fermentation of cellulose has failed so far to throw any further light on the problem, but it is still being continued, and progress has been made with the translation on a technical scale of the laboratory experiments on the fermentation of sugars resulting from the hydrolysis of cellulosic material.

Advances have been made by the Food Investigation Board in investigating the freezing of tissues, the preservation of foods, engineering problems of storage and other problems. Work has been carried out to enable the determination of the constitution of any mixed glyceride, on the synthesis of the higher aliphatic acids, and on the deposition of fat in yeast and plant cells.

Useful work is recorded in the report of the Building Research Board, which has investigated the causes of the setting of Portland cement and plaster of Paris, the production of fire-resisting cement, the strength of asbestos cement roofing and the economic firing of kilns. The main aim of the Stone Preservation Committee is to devise methods of recognising the nature of decay in a variety of stones subjected to varying conditions, and it is hoped to gain further insight into the various causes of decay, though reliable conclusions cannot be drawn until the investigation has proceeded much further.

The Chemistry Co-ordinating Research Board has continued work on the slow oxidation of hydrocarbons to form formaldehyde (*cf. J.*, 1923, 42, 415 T). The experiments on the synthesis of formaldehyde from carbon monoxide and hydrogen under compression were abandoned, but as it appears that an oily product containing methyl alcohol can be obtained from carbon monoxide and hydrogen by using high pressures and suitable catalysts, the advisability of further research is being considered. The conditions for the successful production of carbon tetrachloride have been ascertained and attention is being given to the production of methyl chloride. Experiments with the view of finding a cheap disinfectant in place of formaldehyde, have given little prospect of success, but attention is being paid to the recovery of formaldehyde after use in disinfecting wool. The Board concluded that it was impossible to arrive definitely at the cause of the Oppau explosion, but thought that there existed pockets of ammonium nitrate either unmixed with ammonium sulphate or mixed with a proportion insufficient to prevent detonation, a conclusion in close agreement with that reached by the German committee of enquiry. The process for the treatment of aluminium so as to produce a surface film of oxide which would readily absorb other suitable protective substances, and thus become highly resistant to corrosion has been examined, and a patent has been applied for. It is recommended that a grant should be made to Prof. I. M. Heilbron in aid of research on certain fish oils the chief constituent of which is a hydrocarbon.

The Engineering Co-ordinating Research Board has financed researches on light alloys, electro-deposition, strength and properties of ferrous materials at high temperatures, fatigue of materials, and various other metallurgical questions. The preparation of a gelatin with low ash content and apparently free from nitrogenous impurities has been accomplished by the Adhesives Research Committee, which has also studied the production of gelatin and high-grade glues from bones, horn-pith and various waste materials. Thus, an odourless and tasteless gelatin having very strong adhesive powers has been prepared from fish skins. Investigation at Bristol University on the nature of adhesion has continued to yield interesting results, though general conclusions cannot yet be drawn. The Fabrics Co-ordinating Research Committee has investigated the action of fire-proofing agents, the deterioration of fabrics and rubber, methods of water-proofing and other problems. The Gas Cylinders Research Committee has instituted work on the physical properties of the so-called "non-permanent" gases, and interesting work has been carried out under the Lubrication Research Committee, which proposes to publish an account of the results obtained. Valuable work has also been done by the Illumination Research Committee, the Forest Products Research Board, the Physics Co-ordinating Research Board, the Radio Research Board, the Current Meters Committee, and the Dental Investigation Committee.

Report of the Government Chemist upon the Work of the Government Laboratory for the Year ending March 31, 1924. Pp. 36. H.M. Stationery Office, 1924. Price 1s. 6d.

During the year 390,421 samples were examined at the Government Laboratory and at chemical stations, an increase of 46,968 compared with 1922–23. There has been an increase of more than 21,000 in the number of samples examined at chemical stations, whilst the number examined at the central laboratories in London has risen from 225,073 to 251,009, an increase of 25,936. Samples of wine, sugar and tea have increased, and there are notable increases in the number of samples of wort, exported beer and spiritous preparations. The number of samples of beer examined for the detection of dilution is again high, being 5079. The number of samples of imported beer has risen from 1361 to 15,283, and of exported tobacco and snuff from 8533 to 17,718. Both these large increases are due to the establishment of the Irish Free State, and the necessary examination of goods passing to and from that country. The work in connexion with the Safeguarding of Industries Act has involved the examination of nearly 8000 samples. The Dangerous Drugs Act and the Dyestuffs (Import Regulation) Act, continue to impose considerable work on the Department. The total number of samples for the Admiralty was 410, which does not include the sea-water samples forwarded by the Admiralty for the determination of salinity.

Of the 867 samples of butter examined during the year, 10 contained more than 16 per cent. of water; three samples described as "hard butter" were preparations of palm kernel fat; and two were described in error as "milk-blended" butter. Out of 455 samples of margarine, five were found to contain more than 16 per cent. of water, but there

was no evidence of excess of butter in any of the samples. The proportion of fat in cheese was found to vary from 8·6 to 38·1 per cent., or from 21·0 to 56·9 per cent. of the dry matter in the cheese; some of the cheese had thus been made from skimmed milk, but no exception could be taken, as there are no appropriate regulations to control composition.

Examination of tinned cream showed that it contained 23 to 54 per cent. of fat, and the preserved cream from 51 to 67 per cent. Out of six samples of tinned sterilised milk examined, two were found to have been deprived of about one-quarter of their fat. The others were not adulterated, but three of them containing ordinary whole milk, bore the new condensed-milk label. Of the 263 samples of condensed milk taken under the Public Health (Condensed Milk) Regulations which came into force on October 1, 1923, 53 samples were reported against. All were, however, found to be free from chemical preservatives. Thirty-six samples of sheep-dips submitted during the year were reported to be defective. Samples of river water, effluents and sea-water were also examined. Various deficiencies and impurities were found in fertilisers and feeding-stuffs.

An enquiry was made under the Merchandise Marks Act into the composition of various agricultural materials, and it was found that one out of seven samples of ground oats, contained 15 per cent. of tapioca flour; another sample contained 85 per cent. of barley and tapioca. Three samples of pea meal were found to contain 5, 25 and 33 per cent. of maize and barley, and four samples of barley meal were found to contain 25, 30, 40 and 50 per cent. of oat refuse and weed seeds, whilst a sample of fish meal contained 10 per cent. of ground cereals and refuse. Two samples of copper sulphate contained 50 per cent. of sulphate of iron.

Altogether, 47,733 samples of beer were examined for assessment of duty. Out of 292 samples of brewing materials tested, 140 were malt, corn, brewing sugars and exhausted grain, and 152 yeast foods and miscellaneous substances used, or proposed to be used, in the preparation of beer. Ninety samples were found to contain arsenic in slight excess of the legal limit. Many duty-free spirits, including methylated spirits, specially denatured spirits and other manufacturing spirits were examined, and the naphtha represented by all these samples with one exception was approved as fit for methylating purposes. Examinations were also made of samples of sugar, glucose and saccharin, tea, tobacco, and wines. None of the 153 samples of matches examined was found to contain white phosphorus.

In connexion with the work done by the Office of Works in the strengthening of the roof of the Great Hall at Hampton Court some oak panels which had been repainted about a hundred years ago were examined. Traces of the original azure blue were found on the wood. This had been covered over with a coating of white lead, and then with a Prussian blue paint. Since Prussian blue was discovered about 1710, it is clear that the blue paint could not have been put on earlier than this date. It is known that the final oak-coloured paint was applied early in the last century.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech. ..	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder	£47 per ton.
Acid Hydrochloric ..	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder ..	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Copper Sulphate	£25 per ton.
Methylated Spirit 64 o.p.—	
Industrial	2s. 7d.—2s. 11d. per gallon, according to quantity.
Mineralised	3s. 8d.—4s. per gallon, according to quantity.
Nickel Sulphate	£38 per ton d/d. Normal business.
Nickel Ammon. Sulphate	£38 per ton d/d. Normal business.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate ..	5¾d. per lb.
Potass. Chlorate	3d.—4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£3 10s. per ton d/d.
Soda Caustic, solid ..	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton, carr. paid.
Sod. Bichromate	4¼d. per lb.
Sod. Bisulphite Powder 60/62%	£17—£18 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst. ..	£9 per ton d/d.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	5¾d.—1s. 4d. per lb., according to quality.
Crimson	1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic, Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide	£30—£33 per ton, according to quantity.
Carbon Black	7d.—7½d. per lb. ex wharf.
Carbon Tetrachloride	£60—£65 per ton, according to quantity, drums extra.
Chromium Oxide, green	1s. 3d. per lb.
Indiarubber Substitutes White and Dark	5d.—9¼d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	£48 per ton, barrels free.
Lead Hyposulphite	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£16 5s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Precip. B.P.	£56—£57 per ton, according to quantity.
Sulphur Chloride	4d. per lb., carboys extra.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep	5s. 1d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£12 per ton.
Grey	£16 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 15s.—£9 5s. per ton, according to grade and locality.
Iron Liquor	1s. 7d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 9d. per gall. Unrefined.
Wood Naphtha—	
Miscible	4s. 10d. per gall. 60% O.P.
Solvent	5s. 3d. per gall. 40% O.P.
Wood Tar	£4 5s. per ton.
Brown Sugar of Lead	£43 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	6¼d. per lb. Quiet.
Crude 60's	1s. 7d.—1s. 9d. per gall, according to district. Market flat.
Acid Cresylic, 97/99	2s.—2s. 1d. per gall. Demand fair.
Pale 95%	1s. 9d.—2s. 1d. per gall. Better enquiry.
Dark	1s. 9d.—2s. 1d. per gall. Quiet.
Anthracene Paste 40%	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	6d.—6½d. per gall. Small demand.
Benzole—	
Crude 65's	7½d.—9d. per gall. ex works in tank wagons.
Standard Motor	1s. 1½d.—1s. 3d. per gall. ex works in tank wagons.
Benzole—	
Pure	1s. 5½d.—1s. 7d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5d.—1s. 5½d. per gall. Small demand.
Pure	1s. 8d.—1s. 9d. per gall. Small demand.
Xylol coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	8½d. per gall. Little demand.
Middle Oil, Heavy Oil, Standard Specification	5d.—6½d. per gall., according to quality and district. Fair business passing. Small demand from America.
Naphtha—	
Solvent 90/160	11d.—1s. 2d. per gall., according to district. A shade firmer.
Solvent 90/190	11d.—1s. per gall. Not much demand.

Naphthalene Crude—
Cheaper in Yorkshire than Lancashire. Demand rather better.
Drained Creosote Salts £4—£6. Quiet.
Whizzed or hot pressed £6—£9 per ton.

Naphthalene—	
Crystals and Flaked	£12—£16 per ton, according to district.
Pitch, medium soft	40s.—45s. per ton f.a.s. Market very flat. No business.
Pyridine—90/160	18s. 6d.—19s. per gall. Steady demand.
Heavy	12s. per gall. Market dull.

INTERMEDIATES AND DYES

Business in dyestuffs has been better since the beginning of the month and further improvement is expected.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 7d. per lb.
Acid H.	3s. 11d. per lb. 100% basis d/d.
Acid Naphthionic	2s. 2d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 1d. per lb. Improved demand.
Acid Sulphanilic	9¼d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	8d. per lb. naked at works.
Aniline Salts	8½d. per lb., naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 1d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C.	4½d. per lb. Rather quiet.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	3s. per lb.
Dichloraniline S. Acid	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£85 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 3d. per lb. d/d. Drums extra.
Dinitrobenzene	9d.—10d. per lb. naked at works.
Dinitrochlorbenzol	£84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine	2s. 10d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. per lb. d/d.
α-Naphthylamine	1s. 4d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.

m-Nitraniline ..	.. 4s. 3d. per lb. d/d.
p-Nitraniline ..	.. 2s. 3d. per lb. d/d.
Nitrobenzene ..	.. 5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	.. 2s. 11d. per lb. 100% basis d/d.
Nitronaphthalene	.. 10½d. per lb. d/d.
p-Nitrophenol ..	.. 1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	.. 3s. 11d. per lb. d/d.
p-Phenylene Diamine	.. 10s. 2d. per lb. 100% basis d/d.
R. Salt	.. 2s. 5d. per lb. 100% basis d/d.
Sodium Naphthionate	.. 2s. 3d. per lb. 100% basis d/d.
o-Toluidine ..	.. 10d. per lb.
p-Toluidine ..	.. 3s. 3d.—4s. 2d. per lb. naked at works.
m-Toluylene Diamine	.. 4s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	.. £47 per ton. Firmer.
Acid, Acetyl Salicylic	.. 3s. 1d.—3s. 3d. per lb., according to quantity. Market firmer.
Acid, Benzoic B.P.	.. 3s. per lb.
Acid Boric B.P. ..	.. Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric ..	.. 19s.—21s. per lb.
Acid, Citric ..	.. 1s. 3½d.—1s. 4½d. per lb.. less 5% for ton lots. Market very weak.
Acid, Gallic ..	.. 3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	.. 6s. 9d. per lb. Resublimed quality 8s. per lb. Market firm.
Acid Salicylic	.. 1s. 6d.—1s. 8d. per lb., according to quantity.
Acid, Tannic B.P.	.. 2s. 10d. per lb. Market quiet.
Acid, Tartaric ..	.. 1s. 1½d. per lb. less 5%.
Amidol	.. 9s. per lb. d/d.
Acetanilide ..	.. 2s. 1d.—2s. 3d. per lb. for quantity. Demand slow.
Amidopyrin ..	.. 13s. 3d. per lb. Neglected. Stocks low.
Ammon. Benzoate	.. 3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	.. 12s. 6d. per oz. for English make.
Barbitone	.. 15s.—15s. 6d. per lb. Quiet market.
Benzonaphthol ..	.. 5s. 3d. per lb. Small inquiry.
Bismuth Carbonate	.. 10s. 6d.—12s. 6d. per lb.
„ Citrate ..	.. 10s. 3d.—12s. 3d. „
„ Salicylate	.. 9s.—11s. „
„ Subnitrate	.. 8s. 8d.—10s. 8d. „
Borax B.P. ..	.. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	.. Market firm.
Ammonium ..	.. 1s. 6d.—1s. 9d. per lb. } According to quantity.
Potassium ..	.. 1s. 4d.—1s. 7d. per lb. }
Sodium ..	.. 1s. 5d.—1s. 8d. per lb. }
Calcium Lactate	.. 1s. 6d.—1s. 9d. per lb., according to quantity. Fair demand and steady market.
Chloral Hydrate ..	.. 4s.—4s. 3d. per lb. Market easier after recent firmness.
Chloroform ..	.. 2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate	.. 6s. 6d. per lb. Little demand.
Formaldehyde ..	.. £49 per ton.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free ..	.. 7s. per lb.
Glycerophosphates—	
Iron	.. 8s. 9d. per lb.
Magnesium ..	.. 9s. per lb.
Potassium, 50%	.. 3s. 6d. per lb.
Sodium, 50% ..	.. 2s. 6d. „
Guaiacol Carbonate	.. 10s. 6d.—11s. 3d. per lb.
Hexamine ..	.. 3s. 1d.—3s. 3d. per lb.
Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor	.. English make offered, 120s. per oz.
Hypophosphites—	
Calcium ..	.. 3s. 6d. per lb., for 28-lb. lots.
Potassium ..	.. 4s. 1d. per lb.
Sodium ..	.. 4s. „
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb.
Magnesium Carbonate—	
Light Commercial	.. £36 per ton net.
Magnesium Oxide—	
Light Commercial	.. £75 per ton, less 2½%.
Heavy Commercial	.. £25 per ton, less 2½%.
Heavy Pure ..	.. 2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	.. 52s. per lb. Cheaper.
Synthetic ..	.. 26s.—35s. per lb., according to quantity. English make. Increasing demand.
Mercurials ..	.. Market very quiet.
Red oxide ..	.. 5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	.. 3s. 6d.—3s. 7d. „
White precip. ..	.. 4s. 7d.—4s. 8d. „
Calomel ..	.. 3s. 11d.—4s. „
Methyl Salicylate	.. 1s. 10d.—2s per lb.
Methyl Sulphonal	.. 26s. per lb.
Metol	.. 11s. per lb. British make.
Paraformaldehyde	.. 2s. 6½d. per lb. for cwt. lots. Not very active.
Paraldehyde ..	.. 1s. 6d. per lb. in free bottles and cases.
Phenacetin ..	.. 5s. 9d. per lb.
Phenazone ..	.. 7s. 2d. per lb.
Phenolphthalein ..	.. 5s. 6d.—6s. per lb.
Potass. Bitartrate— 99/100% (Cream of Tartar) ..	.. 88s. per cwt., less 2½% for ton lots.
Potass. Citrate ..	.. 1s. 10d.—2s. 2d. per lb.
Potass. Iodide ..	.. 16s. 8d.—17s. 5d. per lb., according to quantity. Steady market.
Potass. Metabisulphite	.. 7½d. per lb., 1-cwt. kegs included. F.o.r. London.
Potass. Permanganate	.. 7¼d. per lb.
Quinine Sulphate	.. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Saccharin ..	.. 63s. per lb., in 50-lb. lots.
Salol	.. 3s. 6d.—4s. per lb.
Silver Proteinate ..	.. 9s. 6d. per lb.
Sod. Benzoate, B.P.	.. 2s. 6d. per lb.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite— Photographic ..	.. £13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	.. 16s. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	.. 75s.—82s. 6d. per cwt., according to quantity. Quiet market.
Sod. Salicylate ..	.. Fair demand. Powder 2s.—2s. 3d. per lb. Crystal at 2s. 2d.—2s. 5d. per lb. Flake 2s. 9d. per lb.
Sod. Sulphide—	
Pure recryst. ..	.. 10d.—1s. 2d. per lb.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.

Sulphonal..	15s. per lb.	Easier.
Thymol ..	17s. 6d. per lb.	Very scarce

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.	
Aubepine ..	15s. 3d. ,,	
Amyl Acetate	2s. 6d. ,,	
Amyl Butyrate	6s. 9d. ,,	
Amyl Salicylate	3s. 3d. ,,	
Anethol (M.P. 21/22° C.)	4s. 6d. ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 9d. ,,	
Benzyl Alcohol free from Chlorine	2s. 9d. ,,	
Benzaldehyde free from Chlorine	3s. 6d. ,,	
Benzyl Benzoate..	3s. 6d. ,,	
Cinnamic Aldehyde—Natural..	18s. 9d. ,,	
Coumarin	19s. 6d. ,,	
Citronellol	17s. ,,	
Citral	8s. ,,

Safrol ..	1s. 10d. ,,	
Terpineol ..	2s. 4d. ,,	
Vanillin ..	26s. per lb.	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A. ..	15s. 6d. per lb.	
Anise Oil	2s. 8d. per lb.	
Bergamot Oil	16s. 6d. per.	Cheaper.
Bourbon Geranium Oil ..	35s. per lb.	Cheaper.
Camphor Oil	65s. per cwt.	
Cananga Oil Java	10s. per lb.	
Cinnamon Oil, Leaf	6½d. per oz.	
Cassia Oil, 80/85%	9s. 9d. per lb.	Cheaper.
Citronella Oil—Java 85/90% ..	5s. 9d. per lb.	
Ceylon	3s. 3d. per lb.	Cheaper.
Clove Oil ..	7s. 6d. per lb.	
Eucalyptus Oil 70/75%..	2s. 3d. per lb.	
Lavender Oil—French 38/40% Esters	28s. 6d. per lb.	Dearer.
Lemon Oil	3s. per lb.	
Lemongrass Oil ..	4s. 6d. per lb.	
Orange Oil, Sweet	11s. per lb.	
Otto of Rose Oil—Bulgarian	40s. per oz.	
Anatolian	18s. per oz.	
Palma Rosa Oil	16s. 6d. per lb.	
Peppermint Oil—English	65s. per lb.	
Wayne County ..	30s. per lb.	
Japanese	18s. per lb.	Dearer.
Petitgrain Oil ..	9s. 3d. per lb.	
Sandal Wood Oil—Mysore ..	26s. 7d. per lb.	
Australian	18s. 6d. per lb.	Cheaper.

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before Dec. 1st; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on October 16th.

I.—Applications

Beale, Lunsden, Peddie, and Pirbright, Ltd. Filtering apparatus. 22,846. Sep. 27.

Descombes and Tivalu. Desiccation. 22,372. Sept. 22. (Belgium, 22.9.23.)

Farbenfabr. vorm. F. Bayer und Co. Apparatus for producing intimate mixture between gases and liquids. 22,361. Sep. 22. (Ger., 4.1.24.)

Marks (Sanford Riley Stoker Co.). Pulverising machine. 22,474. Sept. 23.

I.—Complete Specifications Accepted

30,026 (1923). Rafn. *See* XIX.

6256 (1924). Stockman. Crushing or reducing machines. (222,039.)

10,094 (1924). Aktiebolaget Separator. Preventing injurious reaction between a centrifugally treated liquid and air. (218,250.)

10,290 (1924). Edelstahlwerk Röchling Akt.-Ges. and Ziegler. Regenerative furnaces. (218,978.)

II.—Applications

Caspari. Low-temperature distillation of fuels. 22,564. Sep. 24. (Ger., 27.9.23.)

Dempster and Sons, Ltd., Illingworth Carbonization Co., Ltd., Illingworth, and Toogood. Apparatus for carbonisation of fuel. 22,705, 22,706. Sep. 25.

Fairbrother (Jackson Research Corporation). Extracting oil from oil-bearing sands. 22,355. Sep. 22.

Fairbrother (Jackson Research Corporation). Process of distilling shale. 22,445. Sep. 23.

Gray. 22,468. *See* III.

Hermann and Perkin. Distillation and carbonisation of carbonaceous materials. 22,470. Sep. 23.

Marks (Catlin Shale Products Co.). Distillation of carbonaceous material. 22,348. Sep. 22.

Moreschi, and Soc. Anon. Aloformia. 22,492. *See* XX.

Pink. Production of oil gas. 22,683. Sep. 25.

Soc. Anon. Le Pétrole Synthétique. Synthetic manufacture of hydrocarbons. 22,322. Sep. 22. (Fr., 19.10.23.)

Sutcliffe. Manufacture of fuel. 22,365. Sep. 22.

Synthetic Ammonia and Nitrates, Ltd., and Humphrey. Production of combustible gases. 22,595. Sep. 24.

II.—Complete Specifications Accepted

30,162 (1923). Warnant. Gas-producer. (222,003.)

1308 (1924). Coninck. Combustion of fuel. (210,419.)

4611 (1924). Mond (Metallbank und Metallurgische Ges.). Internally-heated fuel distillation shafts. (222,033.)

III.—Applications

Gray. Treatment of hydrocarbon compounds. 22,468. Sep. 23. (U.S., 26.9.23.)

Oberschlesische Kokswerke und Chem. Fabr., Damm and Russig. Purifying crude naphthalene. 22,477. Sep. 23.

Soc. Anon. Le Pétrole Synthétique. 22,322. *See* II.

III.—Complete Specification Accepted

29,313 (1923). Weil, and Chemische Fabrik in Billwarder vorm. Hell und Sthamer Akt.-Ges. Manufacturing pure anthracene and pure carbazole. (221,999.)

IV.—Application

British Dyestuffs Corporation, Ltd., Baddiley, Horsfall, Jackson, and Shepherdson. 22,484. *See* XIII.

IV.—Complete Specifications Accepted

13,246 (1923). Imray (Soc. of Chemical Industry in Basle). Manufacture of intermediate products for making azo-dyestuffs. (221,843.)

26,476 (1923). Bloxam (Akt.-Ges. für Anilin-Fabrikation). Manufacture of dyestuffs for wool of the safranine series. (221,975.)

26,703 (1923). Morton (Hoffman-La Roche und Co.). Manufacture of o-o-diacyl derivatives of diphenolisatine. (221,976.)

3711 (1924). Holliday and Co., Clayton, and Stokes. Yellow colouring-matter of the pyrazolone series. (222,031.)

V.—Applications

British Celanese, Ltd., and Ellis. Treatment of cellulose derivatives. 22,423. Sep. 23.

Clough. Machines for scouring wool etc. 22,723. Sep. 26.

Dreyfus. Manufacture of cellulose products. 22,697. Sep. 25.

Garrow. Treatment of sawdust etc. 22,857. Sep. 27.

Harrison, and Lustrafil, Ltd. Manufacture of artificial silk. 22,277. Sep. 22.

V.—Complete Specifications Accepted

22,218 (1923). Dean. Apparatus for sizing and drying artificial silk and the like. (221,944.)

31,715 (1923). Bergmann, Immerdorfer, and Loewe. *See* VI.

3501 (1924). Soc. de Brevets Textiles. Improvement of vegetable fibres. (211,467.)

VI.—Applications

British Dyestuffs Corporation, Ltd., Blackshaw, and Lawrie. Mordanting, dyeing, etc. cellulose-acetate materials. 22,485. Sep. 23.

Byrom, Lithgow, and Downham and Co. Hank-dyeing machines. 22,378. Sep. 23.

Geigy Akt.-Ges. Preparation of printing pastes. 22,339. Sep. 22. (Ger., 22.10.23.)

Holtmann und Co., Ges. Calico etc. roller printing and inks therefor. 22,572. Sep. 24. (Ger., 14.12.23.)

VI.—Complete Specifications Accepted

29,797 (1923). Silver Springs Bleaching and Dyeing Co., Ltd., and Hall. Dyeing cellulose acetate products. (222,001.)

31,715 (1923). Bergmann, Immerdorfer, and Loewe. Treatment of animal fibres. (208,563.)

VII.—Applications

Govers. Preparing siliceous material. 22,699. Sep. 25.

Hooper. Production of cyanides, cyanamides, ammonia, etc. 22,407. Sep. 23.

Moreschi, and Soc. Anon Aloformia. Manufacture of iodine and bromine from natural waters etc. 22,493. Sep. 23.

Soc. Chimique de la Grande Paroisse, Azote et Produits Chimiques. Production of mixed ammonium and potassium salts. 22,575. Sep. 24. (Fr., 8.11.23.)

Synthetic Ammonia and Nitrates, Ltd. Method of producing nitrogen-hydrogen mixture for synthetic production of ammonia. 22,268. Sep. 22. (U.S., 21.9.23.)

Synthetic Ammonia and Nitrate, Ltd., and Humphrey. Ammonia synthesis. 22,594. Sep. 24.

VII.—Complete Specifications Accepted

23,570 (1923). Casale. Apparatus for the catalytic production of synthetic ammonia. (221,956.)

25,698 (1923). Texas Gulf Sulphur Co. Burning of sulphur. (211,831.)

VIII.—Applications

Automatic Bottle Machine Corp. and McNish. Glass furnaces. 22,679. Sep. 25.

Salerni. Abrading materials. 22,425. Sep. 23.

VIII.—Complete Specification Accepted

15,328 (1923). Kallen. Refractory mass. (221,852.)

IX.—Applications

Soc. Lap. Obtaining polished surfaces in cement. 22,790. Sep. 26. (Fr., 29.9.23.)

Soc. Lap. Process for coating metals upon cement surfaces. 22,791. Sep. 26. (Fr., 29.9.23.)

Spackman. Manufacture of cementitious materials. 22,329. Sep. 22. (U.S., 22.9.23.)

IX.—Complete Specifications Accepted

15,333 (1923). Marks (Wiggin's Sons Co.). Controlling the setting of plaster. (221,853.)

15,684 (1923). Clegg and Whittaker. Manufacture of artificial stone or marble.

X.—Applications

Coles. Electrodeposition of metals. 22,405. Sep. 23.

Deutsche Gasglühlicht-Auerges. Manufacture of pure zirconium. 22,590. Sep. 24. (Ger., 25.9.23.)

Marks (Du Pont de Nemours and Co.). Alloys. 22,579. Sep. 24.

Martin, and Sankey and Sons. Stainless iron and steel. 22,514. Sep. 24.

Poole. Flux for soldering aluminium etc. 22,499. Sep. 24.

Salerni. Hardening steel. 22,424. Sep. 23.

X.—Complete Specifications Accepted

15,238 (1923). Marks (Cobb Electro Reduction Corp.). Reduction of ores. (221,848.)

16,539 (1923). Allmänna Ingeniorsbyran H. G. Torulf. Sintering ores. (200,090.)

19,483 (1923). General Electric Co., Ltd. Manufacture of hard alloys. (213,214.)

XI.—Applications

Coles. 22,405. *See* X.

Elektrizitäts Akt.-Ges. vorm. Schuckert und Co. Electrolytic cells. 22,455. Sep. 23. (Ger., 3.10.23.)

Genese and Peto. Electric batteries. 22,753. Sep. 26.

XI.—Complete Specifications Accepted

31,392 (1923). Kalling. Electric furnace. (222,008.)

3551 (1924). Dragonetti. Selenium cells without inertia. (211,161.)

7233 (1924). Western Electric Co., Ltd. (Western Electric Co., Inc.). Soldering. (222,044.)

XII.—Applications

British Oil Products Co., Ltd., Fulton, and Hutton. Treatment of oils for medicinal purposes. 22,513. Sep. 24.

Riedel Akt.-Ges. Process for splitting fats, oils, and waxes. 22,680. Sep. 25. (Ger., 14.11.23.)

XII.—Complete Specification Accepted

5994 (1923). Silica Gel Corporation. Treating oils, waxes, and the like. (195,055.)

XIII.—Applications

British Dyestuffs Corporation, Ltd., Baddiley, Horsfall, Jackson, and Shepherdson. Manufacture of colour lakes. 22,484. Sep. 23.

British Oil Products Co., Ltd., Fulton, and Hutton. Treatment of paints etc. 22,512. Sep. 24.

Heyl. Mineral pigments. 22,747. Sep. 26.

White (Goodrich Co.). Heat-plastic materials. 22,568. Sep. 24.

XIV.—Complete Specifications Accepted

18,439 (1923). Naugatuck Chemical Co. Halogenating the dry latices of india rubber etc., and compositions and articles made therefrom. (201,898.)

27,784 (1923). Duke. Vulcanising rubber. (221,992.)

931 (1924). Wild. Utilization of vulcanised rubber waste. (222,016.)

XV.—Application

Farb. vorm. Meister, Lucius, und Brüning, Kränzlein, and Voss. Manufacture of tanning substances. 22,465. Sep. 23.

XVII.—Application

Corn Products Refining Co. Method of making starch-converted dextrose. 22,350. Sep. 22. (U.S., 11.4.24.)

XVIII.—Complete Specifications Accepted

15,797 (1923). Boidin and Effront. Manufacture of diastases by means of oxidising ferments. (221,860.)

XIX.—Applications

Blunk, Fries, and Imhoff. Sewage purification plants. 22,417. Sep. 23. (Ger., 7.5.24.)

Everaert and Lescarde. Preservation of eggs etc. 22,626. Sep. 25. (Belgium, 25.9.23.)

Imhoff. Sewage purification. 22,416. Sep. 23. (Ger., 15.7.23.)

Stead. Preservation of milk powders. 22,671. Sep. 25.

XIX.—Complete Specifications Accepted

26,460 (1923). Industrie en Handel Maatschappij "Hag." Preparing caffein-free coffee beans. (206,145.)

30,026 (1923). Rafn. Treatment of liquids by heat for sterilisation and other purposes. (208,140.)

XX.—Applications

British Oil Products Co., Ltd., Fulton, and Hutton. 22,513. See XII.

Hefti and Schilt. Manufacture of esters. 22,380. Sep. 23.

Johnson (Badische Anilin und Soda Fabrik). Manufacture of organic compounds. 22,557. Sep. 24.

Moreschi, and Soc. Anon. Aloformia. Manufacture of halogen derivatives of natural gases etc. 22,492. Sep. 23.

XX.—Complete Specification Accepted

14,046 (1924). Chemische Fabrik vorm. Sandoz. Manufacture of the cardiac glucoside of bulbus scillæ. (217,247.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number:—*Australia*: Artificial and pure silk (352); Copper plates (A.X./1338); *Canada*: Steel (A.X./1343); *Czechoslovakia*: Pig iron (361); *France*: Oils, fats for soap-making (364); *France and Near East*: Leather (365); *India*: *Burma and Ceylon*: Cast iron (357); *Netherlands*: Indiarubber ware, glass bottles (369); Silk (371); *United States*: Leather (381); leather (B.X./1259).

Notes on Plant and Products

Atmospheric Pollution is now engaging much attention in consequence of the work of the Advisory Committee on Smoke Pollution. The evil effects of smoke are obvious, but in gauging them some means of measuring the amount of pollution is required. Such a means has been provided by two instruments designed by Dr. J. S. Owens and described in a pamphlet issued by the makers, C. F. Casella and Co., Ltd., 49-50, Parliament Street, London, S.W. 1. The first is an automatic instrument for measuring suspended impurity which, in outline, consists of a device which filters two litres of air at regular intervals through filter paper, thus forming a record from which density can be read by comparison with a calibrated scale of standard tints. The second instrument is designed to obtain a deposit from dusty air on a cover glass, on which the dust particles can be counted by means of an eye piece micrometer. The pamphlet gives a description of the instruments and full directions for use. Messrs. Casella also publish catalogues and pamphlets relating to instruments for surveying, engineering, and meteorology, pressure and vacuum gauges and recorders, thermometers, counters, temperature and humidity recorders and other scientific instruments.

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the Dyestuffs (Import Regulation) Act, 1920, made during September has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee:—

The total number of applications received during the month was 449, of which 361 were from merchants or importers. To these should be added 12 cases outstanding on September 1, making a total for the month of 461. These were dealt with as follows:—Granted—326 (of which 289 were dealt with within seven days of receipt). Referred to British makers of similar products—79 (of which 65 were dealt with within seven days of receipt). Referred to Reparation Supplies available—31 (all dealt with within two days of receipt). Outstanding on September 30, 1924, 25.

Of the total of 461 applications received, 385 or 84 per cent. were dealt with within seven days of receipt.

Foreign Company News

The Cie. des Mines d'Anzin and the Etablissements Kuhlmann have founded a company with a capital of 10,000,000 francs for the manufacture of nitrogen products and chemical products in general.

The Société des Ciments du Calaisis is building a large cement factory at Sangatte. The factory will include two rotary ovens giving a total annual production of 80,000 to 100,000 metric t.

The Cie. de Bethune has started work at its new synthetic nitrogen factory at which the by-products of coal are utilised.

The Société Soie Artificielle de Tubize, the British Celanese Co., and several silk manufacturers in Lyons are founding a company with a capital of 65,000,000 francs to work an artificial silk factory at Vénissieux (Rhône). It is intended to begin work at the end of 1925 and to produce 500 kg. of cellulose-acetate silk per day.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council of Pure and Applied Chemistry

which consists of Representatives from

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals and the Royal Agricultural Society.

VOL. 43 NEW SERIES — LONDON, OCTOBER 17, 1924 — NO. 42

EDITORIAL

HE is not dead, says Ptolemy in the prologue to his Almagest, who has given life to science. What do we mean by giving life to such a science as chemistry? And how is the process to be effected? The life of chemistry may be measured amongst other ways by its effect on the community. The theory of numbers, we feel sure, deserves to be a science, but it is difficult to imagine that Wilson's propositions on prime numbers will ever create new industries or be of any practical use. Not that we are prejudiced against Wilson; he was a north countryman and a fisherman and had other good qualities. Judged by its effect on the community chemistry must be not only alive, but in the prime of life. Mr. Woolcock has recently expounded this to us in unmistakable terms and now tells us the subtle arts by means of which the least unsophisticated of chemists achieve their publicity. The life of a science may also be judged by the rapidity of its progress; here again chemistry comes out well from the trial; see in "Chemistry in the XXth Century" how rapidly it is now developing. The future developments are not within our imaginations, but will certainly be prodigious. Future generations will continue the struggle of the highest point of man's wit with the efficacy of Nature. We have witnessed artificial silk; some day when wood is expensive the raw material for this industry will be artificial cellulose or synthetic formose. We imagine, however, that one of the most striking symptoms of a robust vitality is the interest taken in the science by the great mass of mankind. The exhibition at Wembley has rendered most valuable service in this respect to many of the sciences. Chemistry, mechanics, electricity and other branches of science have made an irresistible appeal to millions of visitors. The chemical and engineering exhibits have been thronged by people of all ages. Even so learned an exhibit as that of the Royal Society has been visited by numbers beyond the limit of our vision. Those who have been to Wembley half a dozen times are very grateful to it; those who have not been there at all have missed an impressive sight, an epitome of the British Empire, infinite riches in a little room, the latest achievements of human ingenuity and a triumph of British organisation. We trust that next year we may again pass through the Alchemists' Gate, drink tea in Hong Kong, admire the carving of Burma, the natural products of Canada and Australia, watch the biscuits made for temporarily assuaging the hunger of a younger generation and study the value of gravity by that powerful Attwood's machine, the scenic railway.

* * *

The historical side of science is urged, as worthy of study, by such eminent men as Sir William McCormick and Sir Frank Heath. It has long been a favourite hobby of the amateur, who lacks a profound knowledge of the subject. Turning for a moment to marine biology, it seems that the Romans, though familiar with the oyster and the murex, were unacquainted with the mermaid. A well-known Latin writer commences his oration with the following surprising remarks: If a painter chose to depict a figure the upper part of which was a beautiful woman but the lower part was a fish's tail, when you were admitted to view his picture, could you refrain from laughing? Such pictures are now common and excite no emotion. A friend of ours who takes an absorbing interest in politics tells us that this image explains the whole political situation and the cause of the present general election. The Labour Party, he argues, does not quite deserve the description of beautiful, the upper part is, indeed, fair but not beautiful, something like the late Mr. Justice Cozens Hardy. According to his view, just as many a cricket eleven, so, too, the Labour picture is disfigured by an ugly

tail, composed as most tails are of extremists. A tail is in fact an extremity, the personification of the limit. Now tails sometimes include stings and sometimes rattles; whether Mr. Ramsay MacDonald sought an election to avoid the stings and arrows of his outrageous followers or whether he was rattled, our friend is not certain. In his opinion the late Government has handled several of the most important questions very well; in finance and in foreign politics he considers them to have been skilful and reasonable. The picture, otherwise so pleasing, is spoilt by the hideous tail; the Prime Minister has been cajoled or forced into a situation which is considered fishy. The Primo Minister was led into wrong by a vision of right; the Attorney-General laboured at his brief, but his explanation was obscure. *Decipimur specie recti: brevis esse laboro, obscurus fio.* Now, whether the Premier seeks a general election to avoid the attacks of the Conservatives or the Liberals or his own extreme followers—or, as our friend calls them, prodders—is not clear. Prof. Gowland Hopkins showed last year at Cambridge that many organic compounds are conveniently broken up by the simultaneous action of two reagents, the one greedy for oxygen and the other greedy for hydrogen. A similar process has recently affected the Labour Party. Mr. Ramsay MacDonald attacked by those who think he has gone too far and by those who think he has not gone far enough, hopes by an election to shake off some of the enemies of the mermaid and at the same time to acquire a less dangerous and noisy tail as a support to that sweet reasonableness which is apparent now that he is, like so many Mermaids, on the rocks. To avoid any misunderstanding we may state that the friend we have been quoting is neither Sir Alfred Mond, nor Sir John Brunner, nor Mr. Miller-Jones.

* * *

The firm of Messrs. Longmans, Green and Co. is well known to chemists. Has it not published "Mellor" and "Thorpe," and some other familiar books? It is perhaps not so widely known that it has been publishing books for a couple of hundred years, and that it owns the publishing business of Messrs. Rivington, established in the year 1711. A pleasant and chatty account of the House of Longman, written by Mr. Harold Cox, appears in the *Edinburgh Review* this month, and gives a number of such pieces of information. We were tempted after reading it to glance at our own meagre store of books, and notice how many of our old favourites were published by them. Of Messrs. Longman's earlier publications we found few, but they furnished us with "Scott's Minstrelsy," published in 1812, and "Cowper's Poems," published in 1817. "Kirby and Spence's Entomology" of the year 1837 we used to read with delight, and some volumes of the "Cabinet Cyclopædia," edited by the Rev. Dionysius Lardner in the year 1831, and still worth reading. Our edition of "White's Selborne" is the offspring of Longmans in 1837, and a well-printed book too. Coming to more modern times, we found a favourite bed-side book, "Macaulay's History," and some old school books with which we struggled in former years: "Kennedy's Latin Grammar" and "Williamson's Differential." Longmans have published books of every sort—literature, classics, mathematics and science. It is no little achievement to have published for two hundred years, during the reigns of eight British Sovereigns. The firm was well established in the '45 and a sturdy veteran when oxygen was discovered in 1774—in fact, celebrating its fiftieth anniversary. We can imagine the then proprietors having an extra bottle of madeira in some mansion in Savage Gardens or other fashionable resort of the period. Let us wish them a further spell of another two hundred years; may they continue to publish as good books as those we have mentioned and to be successful and happy! *Chemistry and Industry* has often had occasion to turn to Mellor and to Thorpe, and we fancy that some of the articles we have published by the Rev. Basil Valentine White would have taken different shapes had not "White's Selborne" been handy to assist him in their compilation. It is a matter of regret to find that Basil Valentine himself is considered to be almost a legendary person.

* * *

Dr. Levinstein has given us a history of the dyestuff industry in its early days, which contains information new to most of us, and presents to some extent a line of argument different from the usual ones. He has sources of information, including his own retentive memory, which make his account unusually interesting and give it the authority which belongs only to those who write at first hand. Thanks to him and to Prof. G. T. Morgan, we know the most essential facts in the early history of the coal-tar colours and the present state of their manufacture in this country. As to the future of the industry in this country, in America, in France and in Switzerland, only a political candidate could speak with any assurance, and the history of countries which enjoy the system of elections shows a number of instances of electoral prognostications which have turned out to be exaggerated. In the case of the British Dyestuffs Corporation, Mr. Sidney Webb a few days ago announced that the Government would veto the proposed agreement with the Interessen-Gemeinschaft. Will some new agreement or some new policy take its place? The chief difficulty in recommending any policy is the ignorance most of us possess of the details of the business of the Dyestuffs Corporation. There is no good reason why these business details should be disclosed to the public, and yet indirectly the public is a good deal concerned. In many such difficulties, the writing down, in accurate terms, of the essential facts is a method of indicating the only possible policy. Probably a careful judicial survey of the whole position, looking at the dyestuff problem from the national point of view, would be of great value. The directors of the Dyestuffs Corporation are bound to consider the problem mainly, even almost exclusively, from the point of view of their own shareholders. Hardly anyone else has now the detailed information necessary for an impartial survey of the situation.

THE BRITISH EMPIRE EXHIBITION

The British Empire Exhibition at Wembley is a veritable microcosm; it includes countries from every continent ranging from the tropical to the polar. It comprises amusements, art, music, engineering, coal mining and every other industry, and it has a scientific side which is almost equally varied. In several of our previous issues we have described in considerable detail the exhibits of chemistry and chemical engineering; we have not had an opportunity of mentioning all of those that deserved mention, but in this article we hope to rectify the more important of these omissions. We have also not done justice to that wonderful exhibition of Pure Science arranged by the Royal Society. The Royal Society excluded chemistry from its arrangement so as to avoid clashing with the exhibits in the Palace of Industry, and it generously helped in that province which forms the "debatable land" between chemistry and physics. Its own exhibit, in the British Government Pavilion, contains important and interesting exhibits dealing with geophysics, zoology, botany and physiology, but the greater part is taken up by a most valuable physical exhibit. The structure and nature of matter, electricity and the atom obviously are of supreme interest. The handbook prepared by the Royal Society is very helpful; it is readable and good. It would be twice as good if it were twice as long: perhaps even its excellence would have varied with the square of its length. There is not a chapter in it which does not make the reader wish for more. Sir Joseph Thomson, Sir William Bragg, Sir Ernest Rutherford and Dr. Aston have written the portion which deals with atomic physics; it is fortunate for the public that they each have a gift for popular exposition. They have themselves done original work of the highest quality and considerable quantity, and the apparatus and devices shown are of historical importance. These include the apparatus by which the existence of electrons was detected and their mass and velocity measured, the earliest photographs of positive ray spectra, Fleming's original rectifying valves, Aston's mass spectograph, Wilson's photographs of ionising particles, Joly's photographs of the haloes caused by radioactive minerals, early incandescent lamps of the period 1880—1882, Crookes' tubes, Bragg's ionisation spectrometer, diffraction gratings and extremely delicate apparatus for refinements in measurement, ultra-micrometers, crystals of metals and sections illustrating the structure of metals and alloys. There are besides these very many other pieces of apparatus illustrating the phenomena of heat, electricity, light, explosions and many astronomical exhibits of singular interest.

The exhibits and the handbook also deal with such interesting topics as relativity, the structure of stars, spectra, the rare gases, the atmosphere, its water vapour, the phenomena of rain and thunderstorms, the origin of man, the circulation of the blood, muscular work and mimicry. There is an excellent chapter on weather forecasting by Colonel Gold, with special mention of cyclones. Prof. Woodward describes the skulls of the earliest men, and shows casts of the Piltdown skull and that recently found at the Rhodesian Broken Hill mine. The Natural History Museum shows diagrams illustrating Mr. Carruthers' work on the evolution of the carboniferous corals. One must have more time; there is so much to learn, so much to see, so many people to talk to, so much to read, and alas, so much to write.

PALACE OF INDUSTRY

The Chemical Section

History relates that when the famous French author Stendhal wished to write a sentimental novel, he used to re-read a few dozen pages of the Penal Code, "to acquire the atmosphere," as he said. To write about the British Empire Exhibition, the Official Catalogue provides an unfailing stimulus. Repeated visits have brought, not weariness, but the conviction that at least another year is wanted before the average human brain can grasp the details of the unrivalled pageant of industry and Empire that is set out at Wembley. The effect of the Exhibition cannot yet be measured, but the interest taken by the public in the Chemical Section, as well as in the scientific exhibit which shows so strikingly the vigour and resource of British chemistry, suggests that even those who still try to solve the question, "When is a chemist not a chemist?" will realise what is the true answer. The Exhibition is so packed with food for thought that it is perhaps as well that exigencies

of time and space strictly limit the length of this account, otherwise one might go on for ever. Mention cannot be made of all the thousands of exhibitors and the myriads of exhibits, and to avoid any question of precedence the different firms will be dealt with in alpbabetical order.

The stand of Baird and Tatlock (London), Ltd. is so arranged that the first thing to catch the eye is a fascinating little model of a laboratory bench, and when this has been inspected there are enough interesting things to tempt a lengthy stay. One visitor, after inspecting the latest types of balances and hydrogen-ion concentration apparatus went away richer by a number of handsome publications, which the publishers modestly call "circulars." There was one of Electric Furnaces and Pyrometers, others on Apparatus for the Determination of Hydrogen-ion Concentration, Electrometric Titration Apparatus, the "Hurrell" Homogeniser (a new high-speed film mill), and a tempting list of pure chemicals, reagents and stains. One can only advise those interested to obtain these circulars.

A stand which is an excellent illustration of the wide meaning that must be attached to the words "chemical industry" is that of F. W. Berk & Co., Ltd., a firm which has manufactured and merchanted chemicals since the Franco-Prussian war. Acids, which are the firm's pride, are to be seen—accumulator, sulphuric, dipping, hydrofluoric, hydrochloric acids, as well as organic acids. The protection of ships against corrosion and fouling requires the use of large quantities of chemicals annually, and of these products suboxide of copper, sulphocyanide of copper, and the red and yellow oxides of mercury are on show. Messrs. Berk also exhibit tin oxide, hydrogen peroxide in liquid form as well as in solid form for export, alkaloids, mercury salts and a wide range of crude drugs. The visitor will also see the products which the firm imports, particularly sulphur, mercury, potassium salts, earths, ochres and many other materials, and will note the care with which packing is carried out, an important consideration for consumers at home or abroad.

British Drug Houses, Ltd., provide at their stand an elegant brochure which gives an interesting account of some of the firm's chief products, such as various aids to beauty. Readers of this *Journal* will think rather of the "B.D.H." fine chemicals, of their invaluable series of standardised solutions and reagents for analysis, of their indicators for use in the determination of hydrogen-ion concentration and last, but not least, of the B.D.H. insulin. In an exhibition, it is difficult to show everything the firm makes, so it must be remembered that the B.D.H. list of chemicals for research and analysis already includes the names of over 3000 substances, and is continually being added to. A feature of the list is that, although it refers mainly to chemicals of definite purity, the prices are also given of commercial qualities, so that a convenient source is available of [illegible] quantities of commercial grades that can be bou[illegible] bulk, but not easily by the pound.

The aim [illegible] British Dyestuffs Corporation has been to [illegible] the public. There is no overwhelming displa[illegible]ffs in bottles to dismay the onlooker, but the sheen of silks, the glow of many coloured textiles to arouse his interest. And while he is looking at the exhibit showing the Indian process of knot dyeing, his eye will be caught by a model of a two-bay shed illustrating the manufacture of a simple dyestuff in all stages from the coal-tar to the grinding and weighing machine. All the products yielded by the process in actual practice are to be seen in bottles placed in a separate stand. Those "experienced in the art" will be able to obtain at the stand a booklet on the dyeing of artificial silk which describes the various kinds of artificial silk and their dyeing properties. The Cellutyl colours have been specially manufactured for the purpose of dyeing "Celanese," a cellulose acetate silk, and brilliant examples of the results they give are to be seen in cases. The thoughtful visitor will do well to ask for the Corporation's brochure on "The British Dyestuffs Industry, 1856-1924," and in it he will find an excellent account of the vicissitudes of the industry, and will gather something of the magnitude of this undertaking, born out of the stress of war.

The stand of Brunner, Mond and Co., Ltd., and their associated companies is one of the most interesting in the Chemical Section, as it is also the largest. The Brunner Mond specialities—soda ash, caustic soda, sodium bicarbonate, soda crystals, "Crescent laundry soda," "Crex," calcium chloride, ammonium chloride, ammonium carbonate, and sulphate are too well known to need comment. Perhaps the most significant item in the display is silicate of soda, a subject to which Messrs. Brunner Mond have devoted extensive research work for a number of years past. One of its most valuable applications is for the hardening of concrete, and Messrs. Brunner Mond now supply a special grade, known as P. 84, for this purpose, which contains 3·3 molecules of silica (SiO_2) to 1·0 molecule of soda (Na_2O). The result of treatment is that all the pores are completely filled to a depth of ¼ in.—½ in. with a silicious mortar or binding material, giving an intensely hard outer layer, a feature of the stand being the motor-driven abrasion machine demonstrating the great increase in hardness of concrete treated in this way. Silicate of soda in many different grades is also used in making acid-proof cements, as a size for paper, for making soaps, and as an adhesive, and further important developments may be expected.

The Castner-Kellner Alkali Co., Ltd., Runcorn, exhibit at the same stand a large range of electrolytic sodium and chlorine products, including caustic soda, bleaching powder, liquid chlorine and sodium peroxide. The Electro Bleach and By-Products, Ltd., Middlewich, are showing bleaching powder, caustic soda, soda crystals and ammonium carbonate. A wide range of heavy chemicals is shown by Chance and Hunt, Ltd., Oldbury, including sulphuric, nitric and hydrochloric acids, sodium sulphide, saltcake, pure table salt, caustic soda, ammonium carbonate and oxide of iron pigments. The Buxton Lime Firms Co., Ltd., Buxton, show lime in practically all forms, including a very pure form of hydrated lime containing almost 100 per cent. $Ca(OH)_2$. The Synthetic Ammonia and Ni-

trates, Ltd., Billingham, have a very interesting exhibit of ammonia and sulphate of ammonia which is made from the nitrogen of the air by a modification of the Haber process.

Essential oils are the speciality of W. J. Bush and Co., and on their stand there they are in quantity. All the perfumes of the Spice Islands seem to have been ravished for our delectation, and the pleasant habit of allowing names of localities to appear on the stand is a further delight, for who can resist products from Mitcham, Messina or Grasse? But there are also harmless dyes for colouring food, flavouring and fruit essences, fixed oils, fats and waxes, synthetic vanillin of perfect purity, many chemicals ranging from benzoic and salicylic acids to isinglass, gelatin and menthol. There are ammonium chloride and anhydrous aluminium chloride, chloroform and cream of tartar, potassium bromide and sodium bicarbonate. There is ample choice and everything of guaranteed purity.

Burt, Boulton and Haywood, Ltd., have a joint exhibit with the Midland Tar Distillers, Ltd., the Southwestern Tar Distilleries, Ltd., and Synthite, Ltd. Pride of place is, of course, given to coal tar and its products such as refined tar, Tarphalte and Tarvia "B" for road work, pitch for briquetting and varnish, lamp carbons, greases, naphtha, anthracene oil, naphthalene, creosote, phenol, cresol, toluol, benzol, ammonia in various forms, syntan, "Superac Z" (a rubber accelerator), and even lawn sand. There are models of continuous tar-distilling plant, for the use of which Messrs. Burt, Boulton and Haywood are prepared to grant licences, as well as a complete model of a creosoting plant. Of much interest are the specimens of Synthite, either as an amber-coloured substance for use in making electrical varnish, as a plastic material, or, in its final form, as a hard solid in many beautiful colours used as an ornament or an insulator. Synthite, Ltd., are the largest makers of formaldehyde in the British Isles and consequently make a feature of their 40 per cent. vol. material.

The Clayton Aniline Company, Ltd., has arranged its stand so as to provide a survey of the manufactures of the firm, samples and exhibits being shown to illustrate the stages of the working up of raw materials into finished products and the industrial applications of the dyestuffs thus obtained. Textiles, leather, painting and printing are a few of the industries that use the company's dyes. Prominence is given to the Clayton Aniline Company's well-known Magenta, shown in the form of powder and crystals.

The soap made by Joseph Crosfield and Sons, Ltd., could provide the writer with many a text, but when the audience is a chemical one, caustic soda, glycerin and silicate of soda constitute ample themes. The difficulty with silicate of soda is rather to suggest uses for which it is not fitted. A material that can be used for cementing high-speed abrasive wheels or dust-proofing concrete, for sizing paper or making ink is not an ordinary product. There it is, as glass or solution, and there is carbosil, doucil (the new base-exchanging and vapour-absorbing material), and even cement. This is merely a glimpse into the wide field of the heavy-chemical industry, as illustrated by Messrs. Crosfield and Sons.

One of the earliest manufacturers of Magenta was Dan Dawson Brothers, a firm founded in 1858, which also made Soluble Blue, Chrysoidine and Bismarck Brown. To-day the works of the Colne Vale Dye and Chemical Co., Ltd., stand on the same site at Milnsbridge, near Huddersfield, as the original factory of Dan Dawson Brothers. At the company's stand one can see the same colours as those made by its predecessors, and many others besides to show the immense strides that have been made since those early days. There are dyestuffs for textiles, paper, jute, leather, wool, ink, paint and varnish, whether blues for inks, nigrosine for boot polish, or Bismarck brown for leather or furniture. The firm watches carefully over the quality of its products, and maintains a research staff to investigate its manufactures and discover new ones.

A chemical engineering firm such as W. J. Fraser and Co., Ltd., of Dagenham, is rather at a disadvantage in an exhibition, as there is not space for the installation of large plants. Messrs. Fraser and Co., however, have instructive models showing the working of various types of chemical apparatus and photographs are shown in number, so that the visitor can appreciate the chief features. Autoclaves, stills, condensers, dephlegmators, heaters, coolers, driers, stirring gear, pans, tanks, pumps, conveyors are a few of the types of apparatus made at Dagenham, and one cannot conclude without mentioning the Mills-Packard sulphuric-acid plant, of which Messrs. Fraser are the British agents.

The Gas Light and Coke Company, Ltd., continues to grow in size, and fearsome statistics are to be had showing the miles of piping needed to supply its myriad customers with millions of cubic feet of gas. This, the chief side of its activities, is only hinted at in the Chemical Section, but the exhibit has driven home to the visitor the importance of the gas industry, not only as a source of heat, light and power, but as a source of indispensable chemicals. Thus the stand contains specimens of tar, pitch and naphthalene in various forms, carbolic acid and its numerous derivatives are there in array, there are ammonia, toluol, solvent naphtha and the prussiates of potash and soda, as well as beta-naphthol and salicylic acid. Of interest are the various shades of Prussian and bronze blues both in paste, lump and powder form, all guaranteed to be pure colour.

Self-contained manufacture is the keynote of the stand of the Bradford firm of Hickson and Partners, Ltd., who state that the only raw materials they purchase from outside sources are sodium nitrate, crude benzol, and sulphur either elemental or as pyrites. A case shows how the various products are obtained, starting from crude benzol. Messrs. Hickson usually sell their intermediates to other dyemaking firms, which carry out the production of the finished dyestuffs. Aniline is a speciality, but a few finished dyestuffs are produced, two important ones being magenta (sold under its original British name of "Roseine") and sulphur black. The firm owns the British Patent rights of Vidal's sulphur blacks, of which a series is now marketed.

Messrs. Hickson take a just pride in the perfection of their plant, so that products of consistent purity can be obtained, and much importance is rightly attached to their research department, which is devoted exclusively to the development of new products.

The lover of fine chemicals will find much of interest at the stand of Howard and Sons, Ltd., whose products also include those of their branch house, Hopkin and Williams, Ltd. All the chief pharmaceutical chemicals are on show, some of the specialities being benzoic acid and benzoates, salicylic acid and salicylates, anæsthetic ether, isopropyl alcohol for making perfumes, the caseful "bismuth carb. P.B.," and many other bismuth salts, calomel, hydrogen peroxide in 10 vol. and 20 vol. strength, the well-known Howard's magnesium sulphate, sodium bicarbonate and sodium sulphate, synthetic menthol, and various volumetric solutions. Perhaps the most interesting exhibit is the fine range of quinine salts and synthetic quinine derivatives, the latter furnishing some valuable anæsthetics. Hopkin and Williams, Ltd., are, of course, known as the makers of standard analytical reagents, in the production of which this firm was the pioneer in the Empire, and on their stand will be found many other fine chemicals, amongst which are a series of thorium salts used in making gas mantles, uranium and cerium compounds for ceramic products, and cerium salts used in tanning and dyeing.

The exhibit of Johnson, Matthey and Co., Ltd., can be classified in sections. One section illustrates the rare and precious metals in which the firm has so long specialised, gold, silver, platinum and related metals being shown in natural or crude form and in the finished state after refining. The early development of platinum as a commercial metal is largely the history of the firm, and it is interesting to note that the standard metre kept in Paris is also made by them. Another section includes preparations of gold for use in electroplating, photography, and in ceramics, the indispensable nitrate and cyanide of silver, metallic oxides used to impart colour to enamelled ware, lustres for ceramic wares, underglaze colours, glaze and body stains, and colours for use on glass. Antimony, bismuth and mercury and various of their salts are to be seen, and completed articles made from metals supplied by Messrs. Johnson, Matthey, round off a fascinating display.

It would be a confession of ignorance not to be able to say what products are to be found on the stand of the Mond Nickel Company. Everyone knows the Mond nickel and the Mond sulphate of copper, so a visit can be paid to the firm's second stand in the Palace of Engineering, where Henry Wiggin and Co. are ready to educate the prospective client in the uses of the alloys of nickel [illegible] copper and zinc (nickel-silver), with copp[illegible]d with chromium. There are the Ferry [illegible]onstantan alloys used in electrical resista[illegible] Brightray and Redray alloys with their [illegible] to high temperatures, and Corronil, an [illegible] remarkable resistance to heat and cor[illegible]dmirable little booklets are to be obtained from Messrs. Wiggin which set out the history of the different alloys and give tables of mechanical and chemical properties. Cobalt both as metal and as compound is the subject of another booklet and there are also interesting exhibits.

Chemical manufacturers will be attracted by the display of ebonite goods on the stand of David Moseley and Sons, Ltd., a firm which has been making these goods for a long time, some of them still being in use after 25 years' service. There are pipes, bends, taps, pumps, sparge boxes and specialities for all trades, in addition to hose and all sorts of mechanical goods. Tyres are predominant on this stand, but the illustrations of the work that can be done with ebonite should not be missed.

The exhibit of Murgatroyd's Salt Works, Ltd., shows that salt can be as much a fine chemical as it is, ordinarily, a heavy chemical. This firm specialises in the production of two qualities of salt, one of medicinal quality which conforms to the requirements of the British Pharmacopœia, and the other of analytical quality, guaranteed analytically pure. Salt for all the ordinary purposes is also supplied by the firm in any amount or quality.

Newton, Chambers and Co., Ltd., as would be expected, concentrate on the exhibition of the many applications of "Izal," but they have other claims on the interest of the chemist, despite the claims of the many informative exhibits on their stand. They supply cast iron and steel work for chemical factories and by-products plants, they own collieries, distil coal and make a variety of chemicals.

The whole stand of the Nobel Industries, Ltd., is so interesting that there is some danger of neglecting the exhibit of Necol Industrial Collodions, Ltd., which is owned by the former company. Collodion is used in modern industry for a great variety of purposes, and the Necol collodions are supplied in colours and possessing qualities to suit the user's requirements. Other products of this firm are collodion cottons and pyroxylin for all technical and industrial purposes. The industrial applications of the firm's products to leather and other materials are well illustrated.

One cannot but call attention once more to the charming rubber "garden" on the stand of the North British Rubber Co., Ltd., with its loggia, its rubber fountain with rubber water-lilies and goldfish. The crazy paving illustrates one of the forms of the Paraflor rubber carpeting which has been supplied by this firm to so many exhibitors at Wembley, over 30,000 sq. yards having been laid. Such a convenient floor covering will find many uses, whether in the home or in industry, and the rubber "garden" will linger in the memory as a pleasant reminder of the company and their products.

Anthraquinone dyes for silk and cotton and acid alizarine dyes for wool are the specialities of Scottish Dyes, Ltd., who apply the name Caledon Colours to their products to show what good things come across the border. Two new colours produced by this firm are Caledon Red Violet 2RN and Caledon Brilliant Violet R, and samples show the fine shades

they produce, the former colour being used in combination with Caledon Red BN for dyeing casement curtains. The firm's standard products are shown together wlth textiles on which the dyes have been used, and there are also interesting specimens of intermediates, amongst which mention may be made of methylamino hydrochloride, phthalic anhydride and naphthanthraquinone. Other dyestuffs of interest are Solway Green and Solway Blue Black, which are equivalent, respectively, to Alizarine Cyanine Green and Alizarine Blue Black. Here again the evidence of careful manufacture supported by sustained research will convince visitors of the ability of the industry.

The familiar "Metro" brand calls attention to the stand of the South Metropolitan Gas Company, at the sign of the Benzene Ring. Here wood stained in delicate shades with creosote competes for attention with the samples of smokeless fuel, and the dazzle of sulphate of ammonia draws the eye from the cabinets containing a selection of Metro chemical products. Intermediates for dyes, sodium sulphide for the tanner or dye-maker, "hypo" for the photographer, sodium salts for the glass maker, ammonium chloride for the galvaniser or for making electrical batteries, all these are shown. And there is sulphuric acid of all strengths and enough coal-tar products —benzol, toluol, solvent naphtha, creosote oils, cresylic acid, pyridine and anthracene—to impress the most incurious with the mystery and value of raw coal.

Spencer, Chapman and Messel, Ltd., are so well known as makers of sulphuric acid that nothing need be said about their product, save that it is to be seen in all strengths, whether for accumulators or for laboratory or other use on their stand, flanked by displays of hydrochloric and nitric acids. There are also samples of saltcake, nitre cake, and iron oxide for use in industry. The simplicity of the display is highly effective.

Messrs. Stafford Allen and Sons have provided an exhibit that combines interest with instruction. Plants that yield the perfumes for which the firm is noted are shown growing in pots; there are specimens illustrating the yields and qualities of essential oils obtained, and there is a small extraction press to show how the oils are extracted. Packed products complete a stand which is notable for the care with which it has been thought out. Numerous specimens are shown of crude and refined drugs, the packing and display of which is most creditable.

The Thermal Syndicate, Ltd., has an impressive collection of their Vitreosil articles made in fused silica ware and technical difficulties seem to offer no hindrance to the production of any form or size of apparatus within reasonable bounds. An objection has been raised that Vitreosil ware is fragile; this is true, but in actual practice it has been found that more care is taken of articles made of Vitreosil, so that it actually lasts longer. The well-known "Vitreosil" gas globes are a special feature of the stand, but the chemist will find all the important laboratory material and the manufacturer will be interested in the basins, beakers and balloons for use in making mineral acids, some fine, large condensing coils, coolers, distillation apparatus, Glover tower fittings, plant for the production of acids, in fact for any process in which resistance to corrosion and changes of temperature is necessary.

Thos. Tyrer and Co., Ltd., have a representative display of their "Sterling" brand chemicals, important products being their bismuth salts, hypophosphites, mercurials, siccatives, acids and ethers and a large number of granular and scale preparations. Salts of nickel, antimony, manganese, barium, potassium, copper, zinc and tungsten and other metals are also being shown, but it is to be regretted that reasons of safety have prevented the exhibition of their acetone, amyl acetate, pyroxylin and collodions, which are now utilised by so many industries and in so many forms. The analyst is catered for equally with the pharmacist, and photography, rubber vulcanisation and anti-fouling compositions, to mention but a few, all pay tribute to the "Sterling" brand chemicals.

One cannot add much to the previous note about the United Alkali Company, and if there possibly is anyone in any industry that does not know their products, a visit should be paid at once to the company's stand. There can be obtained a pamphlet which describes the company's manufactures and their applications. Agriculture, building and decorating, ceramics and cements, disinfectants and cleansers, dyes, explosives, food products, tobacco, leather, medicine, metallurgy, paint, paper, textiles, oils and fats, all are furnished with some product from bath crystals to paranitrophenol, from chlorine to zinc chloride, from acetic acid to baking powder. For the technician another booklet is provided which summarises the chief manufactures of the United Alkali Company, namely, mineral acids, ammonia, bleaching agents, disinfectants, salt, and, of course, soda ash and various sodium salts. It is of interest to mention the company's Chloros disinfectant, which, when used in the proper proportion for sterilising sewage has been found to have no ill effect upon fish. This disinfectant is also largely used, on account of its detergent and sterilising action, in breweries and distilleries, and it is of value for cleaning bottles. To give a further illustration of the wide field covered by this old-established company, other manufactures included standard copper, purple ore, sulphur, calcium carbide, commercially pure antimony pentachloride, arsenic, and even chloroform.

PALACE OF ENGINEERING

Insulating and packing materials of every description are exhibited by Attwater and Sons on their stand. All the most approved types of insulating material for electrical work are there and the chemical engineer will find packing suitable for every kind of joint, belting, mica, vulcanised fibre, and some interesting bakelite and ebonite products. Much depends on material used for packing and insulation, and the products of a firm which has specialised in these materials will repay close attention.

The stand of Sir W. H. Bailey and Co., Ltd., also contains a good deal of interest to the chemical engineer. The Bailey air compressors and vacuum

pumps are well known and so are the Bailey pumps, whether ram, piston, centrifugal, rotary or hand pumps. A variety of hydraulic plant is illustrated and the inquirer can obtain information about products ranging from fusible plugs and acid pumps to steam injectors, autographic recorders and turret clocks.

Bell's Poilite and Everite Co., Ltd., show a variety of their well-known Poilite and Everite products, but the biggest display of Poilite flat sheets is to be found on the acres of roofs at the Exhibition which are lined exclusively with Poilite. Everite roofing sheets of various forms are shown, and it is worth noting that the makers claim that Everite becomes stronger with exposure, and as it is impervious to weather and resists fire, rot, and chemical action, it is an attractive material for the constructional work in chemical factories.

Centrifugal machines and hydro-extractors monopolise the stand of Thomas Broadbent and Sons, Ltd. There are machines to be seen in metal or plan which are driven by steam, belt, electricity or water and are used for drying granular materials such as sulphate of ammonia, naphthalene, sugar, nitrates and crystals, or for separation, decantation, clarification, precipitation, degreasing and many other processes. The firm takes a just pride in its products and ensures that they shall represent the latest practice with the help of an efficient technical staff that specialises in problems of centrifugal separation.

Fire-clay goods of all types are exhibited by the Glenboig Union Fire Clay Co., Ltd., a firm which not only profits from the experience accumulated during a very long period of years, but directs its application with the help of a fully equipped laboratory which is responsible for the examination of all the raw material used, of every phase of manufacture and of the finished products. The exhibit includes fire bricks of every description, acid-resistant bricks, special bricks for metallurgical furnaces, gas retorts, bricks for retort settings, coke ovens, glass and chemical furnaces, sewage pipes, junctions and many other manufactures essential to industry. For the Glenboig bricks, it is claimed that they are of unequalled quality for use in furnaces, being extremely resistant to great heat, changes of temperature, and wear.

Amongst the exhibits of the Gwynnes Engineering Co., Ltd., are a steam turbine-driven pump of the two-stage impulse type, some of the "Invincible" multi-stage pressure pumps for work such as drainage and loading oil, fire pumps of various types, sewage traps designed to permit the use of centrifugal pumps for handling liquids which contain solid material that would choke the pump if it had access to the impeller, and a number of the "Invincible" ball-joints for flexible connexions in many sizes.

When admiring the refrigerating machines exhibited by J. and E. Hall, Ltd., it should be remembered that this firm has been working continuously at Dartford since 1785, so that it is one of the oldest engineering firms in the world. It made the first paper machine and the first trunk engine installed in a ship, and has associations with Richard Trevithick, of locomotive fame. Nowadays, the firm concentrates its attention almost entirely on refrigerating machinery, which is well represented on the stand. There is a large tandem steam-driven carbon dioxide machine for use in refrigerator ships, a high-speed, electrically-driven, enclosed ammonia machine for making ice, a twin-compressor, marine-type, carbon dioxide machine (also electrically driven) for large provision chambers, a steam-driven carbon dioxide machine fitted with a multiple-effect compression system designed to increase the output when external temperatures are high, a small ammonia machine suitable for small cold stores, and a high-speed ammonia machine that is specially designed for small-scale work whether in shops or for the home. The chemical engineer will find much of interest on this stand, and the user of cold storage will find food for thought.

The "P & B" evaporators are to be found on the stand of Aiton and Co., Ltd., of Derby, a firm which specialises on pipe work—the specimens of corrugated steel expansion pipes on show have led to many questions as to "how is it done?" The evaporator on the stand is one of the Prache and Bouillon plants, for which the sole licence in the Empire is held by P. and B. Evaporators, Ltd., the plants being made at Derby. The special feature claimed for this plant is that it solves the problem of make-up feed water, thus avoiding losses due to scale, corrosion and priming, as well as those due to excessive blow-down and low evaporative efficiency. Working is unusually economical and other virtues are claimed for the plant, of which a full description, with working figures, is given in a booklet issued by P. and B. Evaporators, Ltd.

On the stand of Pott, Cassels and Williamson one would expect to find centrifugal machines, and there they are. Little can be said of moment about a firm that, not long ago, delivered an order of 75 electrically driven centrifuges to one of the largest sugar factories in the East Indies. These machines were of the overdriven type, a special feature of the suspension being the solid steel spindle combined with ball and sleeve bearings and self-adjusting rubber buffers. Many types of centrifuge are made to suit each particular class of material, and the firm is always glad to advise on the best type of plant to use.

The Pulsometer Engineering Co., Ltd., show the "Flexala" and "Resiline" centrifugal pumps, which are specially designed for pumping liquids or sludge containing solid or abrasive materials. The pumps are fitted with a rubber-coated impeller with flexible vanes of rubber, thus providing another application of rubber in which its resistance to erosion is utilised.

Near the Bessemer Gate is an exhibit which should not be missed—that of the Ruths Steam Accumulator Co., Ltd. A system of steam accumulation which gives a fuel economy of 15 to 30 per cent., increases the output of the factory by 10 to 30 per cent., and reduces the boiler surface by something like 25 per cent, is worthy of close consideration by every steam user. The Ruths steam accumulator has already been described in this Journal, and its

merits are open for consideration. A particularly striking example of the reduction of boiler heating surface by equalising the boiler load with the Ruths Steam Accumulator is given on the stand; the number of boilers required was reduced from four to two.

Piping of all kinds, for high-pressure steam, refrigeration, gas and water, whether high or low pressure, telephone equipment, boilers, both marine and land, superheaters, turbines and tube wells dominate the display of Stewarts and Lloyds, Ltd. For every purpose for which a pipe can be used this firm has a suitable type, and in case there should be anyone so bold as to doubt, there are test pieces in abundance. There are specimens that have been subjected to cold expansion and cold flattening and cold crushing; some have been "concertinad" while cold; others have been turned inside out, and to make assurance doubly sure there is a small electric motor that compresses and releases a 3-inch expansion bend every 30 seconds, so that by the time the Exhibition closes the bend will have been tortured over 200,000 times, and it could probably continue. To show the capacity of the firm, there is a steel billet weighing one ton, with a piece of tube made from a similar billet, and near by 1-inch gas tubing is bent to spell out "Stewarts and Lloyds, Limited," to show the quality of the material. The secret is that all stages from raw ore to finished article are controlled by the firm, so that quality can be insured and maintained.

Allen West and Co., Ltd., of Brighton, show a variety of switches that are of interest to chemical engineers, as they are designed to stand rough handling, are practically "fool-proof," and perfectly dust-tight; they can also be made "water-tight" to Admiralty specification if required. Another exhibit on the stand is the insulating material developed by Messrs. Allen West and Co., which is used on their switches and other electrical plant.

The power house in the Electrical Section contains some of Messrs. Allen West and Company's switches, and, amongst other apparatus of interest, are three centrifugal separators used for purifying the lubricating oil for the turbines. These centrifugal separators are made by the De Laval Chadburn Co., Lted., and represent the latest type of well-known De Laval centrifuges. The De Laval Chadburn Co., realising that each liquid possesses its own peculiar features, offer to investigate each particular problem so that a bowl can be designed to give the maximum efficiency of separation.

PETROLEUM IN HÉRAULT, FRANCE

As a result of exploration made by the Ministries of Commerce and Public Works and on the advice of the consultative scientific committee on petroleum, a boring near Gabien has passed through petroleum deposits corresponding to a flow of 25 litres per hour. Information on the results of the analyses will be given at a later date.

SOME THOUGHTS ON THE BRITISH DYESTUFF INDUSTRY*

By Dr. HERBERT LEVINSTEIN, MSc., F.I.C.

During each of the last three years you have done me the honour to invite me to speak to you on the British Dyestuff Industry, but it was impossible to discuss the British Dyestuff Industry without alluding, however briefly, to the British Dyestuffs Corporation. It would have been very distasteful to me to say to you one word which might conceivably have had the effect of adding a difficulty, something which might have been construed into a criticism of those in the middle of a task. The position now is in itself so critical that I cannot conceive that any remarks of mine will add to the embarrassment of the chairman, the Government directors or their colleagues on the board of the British Dyestuffs Corporation, and I feel that having kept silent for three years this silence may be misconstrued if it is maintained longer.

Let me recall to you something of the early history of the dyestuff industry in Great Britain. It is often thought that when Perkin discovered Mauvein—the first aniline dye—and proceeded to manufacture it, the British contribution to this industry ceased. The Germans, we are told, with their superior knowledge and love of chemistry, their greater idealism and devotion to abstract thought, took this "small English seed" and made out of it "the precious German garden"—I am quoting from a very eloquent speech made by Dr. Duisberg at the Perkin Jubilee Dinner in 1906. This is, I am persuaded, far from the correct view.

The two outstanding personalities in the Dyestuff Industry in the first fifteen years after the discovery of Mauvein were Englishmen—Perkin and Nicholson. The famous Caro, afterwards of the Badische company, whose great period came later, and Martius, afterwards one of the leading figures in the A.G.F.A., were both in Manchester at Roberts, Dale and Co. Peter Griess was in England, as was Leonhardt—afterwards with Cassella—subsequently the founder of the Farbwerk Muelheim. That distinguished personality, Otto Witt, was at Williams, Thomas and Dower. May I remind you that Witt is the author of that classical report on the German Chemical Exhibit in Paris in 1900. This we can now match with our own publication, "Chemistry in the Twentieth Century," edited by Dr. E. F. Armstrong, a permanent, fascinating and encouraging record of the British chemical science exhibit at Wembley. In a similar way your own British colour index replaces the old Schultz and Julius.

Meister, one of the founders of Meister, Lucius and Brüning, was in business in Manchester. We had, too, not only the factories named and Perkin's colour works, but also those of Simpson, Maule and Nicholson—for fourteen years the largest coal-tar works in the world—under the brilliant direction of Nicholson. That great chemist and great man Hoffman was their adviser. Before 1865 Read Holliday and Sons, L. J. Levinstein and Sons, and

* Abstract of address to the Society of Dyers and Colourists at Bradford, on October 9, 1924.

Dan Dawsons were in existence, and there was no difficulty in getting good chemists adequate in number for the requirements of the industry at that time.

The point I wish to make is that the people who subsequently founded and developed the big German dye works learned their business in England. They found that a lot of money could be made in the dyestuff industry when a knowledge of chemistry was combined with energetic salesmanship. But they also realised that energetic salesmanship was not alone sufficient. They had seen how Perkin had to devise new technical applications before his new chemical invention could be marketed. Hence they developed the technical sales organisation, which is such a very important department of the trained colourist. I must also add that it was in England that the Germans learned how to manufacture complicated chemicals on a large scale.

It was then, on experience gained in this country, that there was built up that great German industry which in 1913 had magnificent sales and strong research organisations, wonderful factories and very good experimental dye houses. But the principles which distinguish the aniline dye industry, an industry unique because dependent for success on inventions, were not introduced by the Germans.

It is worth while to consider these points in a little detail:—

Perkin himself tells us that he had to discover not only Mauvein, but also the tannic acid method of fixing basic dyes before he could sell Mauvein for colouring cotton. There was no method known for fixing basic dyes on cotton. The dyeing instructions, the working out of new dyeing and printing methods, were part and parcel of the industry in England from the very commencement, and were not introduced to the industry by the Germans. Nor did the Germans introduce the methods of systematic research with which their name is so frequently associated. It is very instructive to glance for a moment at the earlier patents.

The year 1856 gave us Perkin's Mauvein.

In 1859 there were patents for Violets from Greville Williams, R. D. Kay, Beale and Kirkham and Price. Further, in this year we have the Magenta patent of Renard Frères and Franc, and also Gerber and Keller.

In 1860 we notice Medlock's famous Magenta patent, first used by Simpson, Maule and Nicholson, and further patents for Violets by J. Dale, Caro, Richard Smith and Coleman. In the same year Gerard and De Laire transferred to Simpson, Maule and Nicholson patents for obtaining an improved Violet.

In 1861 came Laurent and Casthelaz with their Nitrobenzol Magenta process.

The following year, 1862, was a most productive year to which Perkin contributed what was then considered a new class of violets. Simpson, Maule and Nicholson brought out Phosphine, which they did not patent, Roberts, Dale produced Manchester Yellow, and above all, Simpson, Maule and Nicholson discovered the Aniline Blues, Gilbee Soluble Blue and Nicholson made Alkali Blue.

In 1863 came Hoffman's Violet, the patent of which was transferred to Simpson, Maule and Nicholson, and in 1866 Bismarck Brown—or Manchester Brown—was put on the market by Roberts, Dale, the patent being dated 1863.

Methyl Violet, discovered by Lauth in 1861, was brought on the market by Poirrier and Chappat in 1866. This firm oxidised dimethylaniline and patented the production of the Violet so obtained.

This is a wonderful record of work, and you will observe that whenever the names of Germans occur they are always Germans who were in the employment of British firms. The important patents were taken out by Englishmen, by Frenchmen and by German chemists working in English factories.

These inventions, the result of systematic research, developed the industry far beyond Perkin's original discovery. They also taught the German companies in the most practical way possible the money that could be made out of judicious research—in this case largely other people's research. In fact, in those early days the German companies infringed these patents to the despair of the inventors.

Until 1876 there was no adequate patent protection in Germany, consequently German dyestuft factories could exploit the discoveries made by English and French dyestuff chemists.

Hoping to protect himself, Nicholson refused to patent his discovery of Alkali Blue (1862), far and away the most beautiful blue then known. This availed him nothing. According to Ivan Levinstein (Presidential Address to the Society of Chemical Industry in 1902), the Germans made a profit of half a million pounds out of Nicholson's invention.

The advantage of being able to use the research work of other nations without paying a toll is not without example at a later date. The orientation of the dye industry in Switzerland was due to the absence of patent protection in that country until a much later date.

The discovery of synthetic Alizarine in 1869, almost simultaneously by Graebe, Liebermann and Caro in Germany, and Sir W. H. Perkin in England, is another instance of the depressing results of inadequate patent protection. Both processes were patented in England. Neither could be patented in Germany. Graebe and Liebermann's English patent was acquired by the Badische. The latter exchanged licences with Perkin, who thus acquired by arrangement the monopoly in this country for the manufacture of Alizarine, but in Germany there were other makers beside the Badische. There was no monopoly. Anybody could make Alizarine who wished to do so.

The Franco-Prussian War of 1870–1 followed closely on the discovery of Alizarine, and for two years the German development was impeded. In the course of this war great profits were made by the British dyestuff companies. What happened afterwards is of great interest to-day.

In 1869 Perkin had already sold one ton of Alizarine; in 1870 this was increased to 40 tons, and in 1871 to 150 tons.

The Germans, owing to their war, could only start in 1871, but even in that year they sold 220 tons.

In 1873 they sold two and a half times as much Alizarine as Perkin.

In the following year Perkin retired from the contest, and sold his business to Brook, Simpson, and Spiller. Nicholson had already gone. The two great figures disappeared from the English works. There is little wonder in this. To find themselves outdone by the Germans in marketing their own inventions, to find the Germans selling many times the quantities of the dyes they had themselves discovered, was a most discouraging state of affairs.

The Franco-Prussian War over, and with the builders of the British dyestuff industry removed, the future of the German industry was easier. What happened is common knowledge.

In the first place the Alizarine trade passed almost entirely into German hands. In 1881 they made the Alizarine convention and cleared in that year a million pounds profit. They wrote off the cost of their old works, constructed new ones with excellent laboratories and staffed them with good research chemists. The Germans understood, as apparently some never will understand, that only great sales justify great research organisations. It is equally true that only great sales organisations can attract the best research chemists. The reason is not far to seek. The inventor in a dyestuff factory always draws a royalty on the turnover or profits of the dye he has discovered. His income depends therefore on the efficiency of the sales department of the firm for which he is working.

The examples given of Nicholson's Alkali Blue, and of the synthesis of Alizarine, will convince you that those who lived in those days had reason to attribute the decline of the industry to the absence of patent protection in Germany. That subsequently our English patent laws acted detrimentally to the British industry is generally admitted. But in the manufacture of many dyes the Germans had another great advantage. They had no heavy duty on spirit as in England. In 1902 (Silberrad, *J.S.C.I.*, 1902) the cost in England of diethylaniline from duty-free alcohol would have been 5½d. per pound. The actual cost of this product from duty-paid alcohol was 2s. 5½d.

Thus it was more profitable to manufacture dyestuffs in Germany than in Great Britain. Purely commercial, very human and natural reasons took the few men of great talent, such as Caro, Witt and others, back to their native country where they could earn greater salaries and get larger "tantièmes" as a result of the far greater German sales.

It is interesting to speculate what might have happened if Perkin and Nicholson had been interested enough to stay and fight out the commercial war that ensued. Perhaps the history of the dyestuff industry might have been different? Who knows? Leadership counts for much in this industry.

But one thing is clear. If, after the Franco-Prussian War *laissez-faire* had not been the policy of the State, a very different position would have resulted in the country. If the State had provided :—

Duty-free spirit on terms comparable to those enjoyed abroad :

Protection for inventions, and

Prohibition of import of dyes manufactured abroad :

Information concerning foreign products :

Above all, an assurance of a benevolent interest in the industry : do you think that Perkin and Nicholson would have left ?

Yet these are precisely the measures which the State took after the Great War. If Perkin and Nicholson had remained or if any of the other able men in the industry had had these advantages, what policy would they have adopted ?

Would the policy have been to use these facilities for the purpose of securing in the limited home market the highest possible prices to the neglect of the great markets of the world ? I do not for one moment believe it and I go further. I state with complete confidence that if, in the fifteen years preceding the war, during which I was associated with the British dyestuff industry, the Dyestuff Act had been in being the British companies carrying on business here in 1914 would have been extremely powerful institutions.

We never obtained—nor could obtain—one fraction more than the world's prices for our commodities. We always accepted competition prices where we did business. Had we had, as the British industry has to-day, the first refusal for all orders in the home market we should have been immensely strengthened in competing with the Germans abroad. Our costs would have been lower on account of the greatly increased turnover.

To-day the companies now amalgamated in the British Dyestuffs Corporation are weaker than before the war, less dangerous competitors, and a source of great anxiety to all concerned with our great industry.

For this reason, no doubt, the Board of the British Dyestuffs Corporation have, as you know, proposed an Agreement with the I.G. Last April at the annual meeting the chairman stated that the Board will resign if they are not encouraged to complete the agreement, as outlined. The colour consumers, the customers of the company, through the chairman of their association, have definitely stated that they disapprove of the agreement, that they will prevent it if they can, and will welcome an entire reorganisation of the management. Further, the agreement, the headings of which have become known, is opposed by every one of the organised bodies in Great Britain representing pure and applied chemistry, including the Association of British Chemical Manufacturers.

Thus it appears that the policy of the Board and the constitution of the Board is disapproved by the whole of the chemical world, and by their customers, the colour-using interests.

Out of much that is obscure this much is certain. The agreement has not been approved. The situation contemplated by the chairman and his colleagues has arisen. The Board have not been encouraged to complete the arrangements with the I.G., in which they put their faith, and they will, no doubt, tender their resignations.

Let me remind you, however, that both the Board and the agreement were supported at the annual meeting in April of this year by several speakers, men of high standing in the City of London, who represent substantial financial interests in the company.

The public flotation of the British Dyestuffs Corporation in 1919 was, you will perhaps remember, not a success. A large proportion of the shares remained, and apparently still remains, with the underwriters. I view with concern this divergence of views between colour users and those representing the underwriters. We all want a British dyestuff industry, and this must include the British Dyestuffs Corporation with factories employed making good dyes, selling them at reasonable prices, and earning a reasonable return on the capital invested; a company able to supply the home market with satisfaction to its customers, and strong enough to battle for a share in the world's markets. Such a company will satisfy all classes of shareholders, and satisfy the purpose for which Parliament enacted the Dyestuff Act. But you can only get such a company with the active assistance and support of the colour users. In the circumstances an impartial, dispassionate comment on the divergent views can only be helpful, and may be of interest to you. I am a strong supporter of the British dyestuffs industry, and of the British Dyestuffs Corporation, of which I am, I think, the largest individual shareholder. I regard the success of both as vital to the security of British trade in peace and in war.

The argument of what may be called the underwriters is that colour consumers are grasping, and desire to buy dyes below the economic cost of production. Thereby the shareholders are deprived of their natural right to dividends, a matter of more consequence to non-consuming shareholders than to the customer shareholders. After all, the shareholders who are consumers derive the benefit of low-priced dyes, and can look with more equanimity at the absence of dividends than those whose interest in the company is purely financial.

Frankly, I do not think that this can be upheld. I have more sympathy with the consumers' standpoint. Bearing the burden of the Dyestuff Act, they consider that every effort should be made by the most competent persons obtainable to meet the demands of their trade. They are aware of the diminished production of the British Dyestuffs Corporation, their diminished and diminishing share of the British market. They may, with justice, attribute high prices to high overhead charges consequent upon idle plants.

The Dyestuffs Act in their view—and they support the Dyestuff Act, and are prepared to carry it out fairly—cannot be used legitimately to bolster up high prices for dyes; the Act should and can be used very differently, to the great advantage of both consumers and the dye manufacturers alike.

Here, at any rate, lies an apparent though not a real diversity of interests. A shareholder in any business need not be unduly alarmed at the temporary absence of dividends, provided that the value of his shares is substantially conserved. If in addition to the absence of dividends the shareholder is faced with a diminishing asset, he is in a dangerous position. An examination of this point in this specific case leads one at once to consider the situation created by the amalgamation of British Dyes, Ltd., and Levinstein, Ltd., in 1919. In the course of this examination I may be critical. There is a time for criticism, for instructed criticism. To withhold criticism to-day may be as unwise as it may be fatal to resist criticism.

This fusion was brought about by Lord Ashfield, then President of the Board of Trade, now a Government Director of the British Dyestuffs Corporation. In 1918 you had in my firm a dyestuff manufacturing company employing 3000 hands, analogous to but smaller than the large German factories. The analogy lay in these three points:—(1) The business was managed by those who had created or had grown up in it. (2) It was a company with three large factories, large assets, but with a small nominal capital. (3) It had a contented and permanent, not a nomadic, staff, and a harmonious Board.

We never did sell our business, but we consented to put what we considered to be our duty before our inclination or our profit, and we exchanged our holding in Levinstein, Ltd., for, in round figures, some £800,000 shares in the British Dyestuffs Corporation. These shares are now worth less than a quarter of their nominal value.

Now consider the following figures: The British Dyestuffs Corporation have recently recovered about £1,000,000 in E.P.D. from profits earned by Levinstein, Ltd., before the amalgamation. Further, they are entitled to receive, or have already received, from the Du Pont Company the sum of £250,000 in cash, on account of the American rights for the Levinstein processes acquired by the Du Pont Company. The British Dyestuffs Corporation thus obtained their factories, outstandings, stocks, processes, royalties due and goodwill for a little over three-quarter million in shares, and have regained therefrom about £1,250,000 in cash, and the present market value of what is left is about £180,000. I would commend to your consideration the answer to this question. If this particular dyestuff business has in the last two or three years furnished about £1,250,000 of hard cash into the coffers of the British Dyestuffs Corporation out of past profits and in royalties for their processes, why is the market value of their property to-day only £180,000, a tiny fraction of the cost of the factories, large, modern, up-to-date and complete. The great factories and laboratories carefully designed in all ways are there intact. I will venture on the answer.

Simply because the value depends on the earning capacity. The value of a great chemical business depends little on the intrinsic value of the plant and machinery, even though it covers 50-60 acres, but on the earning capacity. This dyestuff works has lost the earning capacity it formerly possessed when in private ownership.

While these factories are stagnant, in spite of the protection of the Dyestuffs Act, their trade is passing into other hands, those of people who know the aniline-dye industry. Others in this country are busy working and enlarging their plant to take over a part of the business formerly held by Levinstein, Ltd.

There appears, therefore, to me to be no doubt that you have an asset which has diminished to a startling extent. You must remember that in

addition to the factories at Blackley and the Claus Plant at Clayton, this figure of £180,000 also includes the value of the Indigo Works at Ellesmere Port. This plant was designed, erected and owned prior to the war by the Germans. It has now double the pre-war capacity, possesses the complete monopoly for the manufacture of indigo in this country, and is amply large enough to supply the whole British demand.

If this picture does not fit in with the complacent words of the chairman at the annual meeting of the British Dyestuffs Corporation it is not my fault. It appears to harmonise with and to explain the anxiety of the Government directors and the Board to get through an agreement—I might almost say any agreement—with the Germans. It tends to justify the severity of the terms demanded by the Germans. We may surmise that it influenced the decision of the Board to retire if they are not encouraged to complete the German agreement.

On the whole, giving due weight to the disadvantages of such a course, these figures do suggest to me that no body of shareholders has cause seriously to resist the declared intention of the directors. That is a point of view I would respectfully urge on all interested in this great question.

In saying this I am sure nobody would desire to be discourteous, or to fail to recognise the great trouble which the directors have devoted to an undertaking which all of them must have found a burden presenting problems entirely foreign to their previous experience. The times are too serious and too difficult for those who care about this industry or have large interests in it to be content with what has occurred. I would recall to you the wise, and as it appears, prophetic words of the Rt. Hon. Sir A. Mond, when speaking in the House of Commons on February 2, 1915: "I speak with a certain amount of experience when I say that it is not sufficient merely to have people who, however able they may be on the commercial side, are entirely ignorant of technical matters, to control a chemical business. Unless you have people on your Board who are themselves capable of appreciating every important invention and discovery in chemical engineering which your chemical engineering staff brings to you, you are very likely to get into the position into which many companies get when the so-called practical men discard all new ideas as being only fads or as being too expensive. If you want to compete with Germany in this industry you must not follow that policy."

I hope that I have not wearied you with this account and with these figures. They are of interest, because the success of the British industry is so important to this Society; and because the successful administration of the Dyestuffs Act is only possible with a successful British Dyestuffs Industry.

The extraordinary analogy between the position of the Dyestuff Industry after the present war and after the Franco-Prussian War has no doubt occurred to many of you.

If the ability to develop this industry were here from 1856 to 1870 why not now when our chemical schools have so marvellously grown! Yet we are told to-day that this country is inherently incapable of competing in this industry which was created and developed here.

Let me close this address by quoting Lord Moulton's words when delivering an address on "The Manufacture of Aniline Dyes in England" in the Manchester Town Hall on December 8, 1914: "Let me deal for a moment with the difficulties that face one. The first is that there is a lack of the necessary technical skill. I have a great difficulty in returning a polite answer to that. To my mind it is nonsensical."

That, too, expresses my mind precisely.

THE INSTITUTION OF CHEMICAL ENGINEERS

At a meeting of the Council of the Institution, held on October 8, 1924, the following gentlemen were elected :—

Members.—Arthur Matthew O'Brien, William Temple Gardner, Sydney Joshua Tungay, Herbert Thomas Fradley. *Associate-Members.*—Arthur Joseph Underwood, William Perceval Paddison. *Graduates.*—Lawrence Gordon Cowen, Henry Oates Richardson, Frederick Estill. *Students.*—Richard Graeme Heggie, Maurice Schumlian.

Arrangements were discussed for entertaining the members of the American Institute of Chemical Engineers who would hold a joint annual meeting with the Institution of Chemical Engineers in England in July next year. The programme proposed is as follows: Sunday, July 5, 1925—Arrive at Liverpool. Monday to Wednesday, July 6 to 8—Chester. Thursday and Friday, July 9 and 10—The Lakes. Saturday, July 11—Glasgow. Sunday and Monday, July 12 and 13—Edinburgh. Tuesday and Wednesday, July 14 and 15—Leeds: Annual Meeting of the Society of Chemical Industry (if on this date). The visitors are to leave on July 18 for America. It is proposed that the tour be made by cars and an organising committee has been formed to arrange details.

MINING AND METALLURGY IN CANADA

A rich deposit of realgar is reported from the Comox district, Vancouver Island, B.C. Analyses of average samples show 57 per cent. arsenic.

The magnetic iron ore found near Pangis, on the line of the Algoma Central Railway, contains 60 per cent. iron. About twenty claims have been located and stripping has begun.

The Granby Consolidated Mining and Smelting Co. has blocked out about 10,000,000 tons on Copper Mountain, Princeton district, B.C. On the opposite side of the mountain the Princeton Mining and Development Co. is engaged in operations. The ore runs from 6 per cent. copper and 2 oz. silver to 20 per cent. copper, 65 oz. silver, and 0·09 oz. gold per ton.

FORTHCOMING EVENTS

Oct. 20. Institute of Chemistry, *Huddersfield Section.* Annual General Meeting." "Chemists' Contracts—Duties and Privileges," by G. S. W. Marlow.

Oct. 21. University of London, King's College, Strand, W.C. 2, at 5.30 p.m. "Recent Developments in High-Speed Internal Combustion Engines," by H. R. Ricardo. Also on November 4.

Oct. 21. Institute of Chemistry, *Leeds Area Section,* The University, Leeds. "Chemists' Service Agreements. Duties and Privileges," by G. S. W. Marlow.

Oct. 21. Joint Meeting of Institute of Chemistry and Society of Chemical Industry, *Edinburgh and East of Scotland Sections,* in the Hall of the Pharmaceutical Society, 36, York Place, Edinburgh, at 8 p.m. Address by W. J. U. Woolcock, C.B.E. Dinner at 6 p.m. in the North British Station Hotel, Edinburgh. Members of the Section and of the Institute of Chemistry are invited to be present. Tickets 8s. 6d. each.

Oct. 21. Institution of Electrical Engineers, The College, Loughborough, at 6.45 p.m. "Realisation of Heat Units in Steam and Electric Power Plant," by F. W. Nicholls.

Oct. 21. Imperial College Chemical Society, Royal College of Science, South Kensington, S.W. 7, at 5 p.m. "The Development of Physical Chemistry," by Prof. J. C. Philip, F.R.S.

Oct. 22. Society of Chemical Industry, *Glasgow Section,* Institution of Engineers and Shipbuilders, 39, Elmbank Crescent, Glasgow, at 7 p.m. "Process Records ond their Bearing on Plant Efficiency," by J. Adam Watson.

Oct. 22. Royal Microscopical Society, at 20, Hanover Square, W. 1, at 7.0 p.m. "Elementary Principles of Microscopical Illumination," by J. E. Barnard. "Super-saturated Solid Sulutions," by Dr. R. H. Greaves. "New Photomicrographic Apparatus," by H. Wrighton.

Oct. 22. The Faraday Society, in the Geological Society's Rooms, Burlington House, Piccadilly, London, W. 1, at 5 p.m. Discussion on "The Physical Chemistry of Igneous Rock Formation," with an introduction by Dr. J. S. Flett. Papers are expected from Prof. C. H. Desch, Dr. J. W. Evans, Prof. J. W. Gregory, A. F. Hallimond, Prof. P. Niggli, Dr. A. Richardson, Dr. A. Scott, Mr. G. W. Tyrrell, and Prof. W. E. S. Turner.

Oct. 22. Institute of Chemistry, *Manchester Section,* Annual General Meeting, The Textile Institute, St. Mary's Parsonage, Manchester, at 7 p.m. "Service Agreements—Duties and Privileges," by G. S. W. Marlow.

Oct. 23. The Society of Chemical Industry, *Chemical Engineeri[illegible] Group,* The Kelvin Room, Engine[illegible] Club, 39, Coventry Street, W. 1, at 5 p.m. (1) "Crystallization," by H. Griffiths. (2) [illegible] Development and Formation of Cryst[illegible] by Prof. T. V. Barker. An Informal Dinn[illegible] follow at 7 p.m., and the Discussion on the two papers will be contiuued at 8 p.m.

[illegible]3. Society of Dyers and Colourists, *West Riding Section.* "The Research Situation—a Criterion of National Stability," by Dr. H. H. Hodgson.

CHEMICAL MEETINGS

The list of chemical meetings published on the opposite page, long as it is, is very incomplete. It includes only the public meetings; there are in addition the council meetings, the committee meetings and sub-committee meetings of the chemical societies mentioned in the list, and also the meetings of the A.B.C.M., the Federal Council and such bodies as the Petroleum Technologists, the Oil and Colour Chemists, the B.A.C. and many other organisations, and the very numerous sections and societies, some of considerable importance, which meet in the provinces. Most of the meetings included in the list are meetings at which papers are read and many of these papers are published. So far as London meetings are concerned, there is but little overlapping and little clashing of dates. Nevertheless, several of the papers read before sectional meetings of the Society of Chemical Industry may be of interest to other London sections, and it is probably worth while to combine some of these meetings. As to the provinces, joint meetings of two or three societies have been tried and have been found successful as well as pleasant. Suggestions have been made in the past, and will be again made, for close co-operation between provincial sections for joint meetings. The publication of the important papers in pure and applied chemistry is becoming a difficult problem, and our correspondence columns bear witness to this. The problem is particularly difficult in pure chemistry, for it is impossible to state now which new compounds will be of importance fifty years hence. As the population of the world increases, the number of scientific workers will increase, and also the number of readers; the cost of printing and paper is also certain to increase. Our readers could render a very useful service to the chemical community if they would think over the essential features of our chemical meetings and our chemical publications, and give the world the benefit of their views.

What is to be done, for instance, with Prof. Urbain, who brings before the French Academy two papers, the one on "*L'Energétique des réactions chimiques,*" and the other on "*Le tombeau d'Aristoxène. Essai sur la musique*"?

The compilation of the list of meetings we should note is mainly due to the care and industry of Mr. G. S. W. Marlow.

It is not clear why all the meetings are held; certainly the social side is an important factor. Many of the papers read are either so technical or so difficult that only a small proportion of the audience can enjoy them. Such papers could usually be taken as read. If a paper is worth publishing, as a rule it is worth while to distribute advance proofs. Some chemists think that a 20 per cent. reduction in volume of most chemical publications would be both possible and desirable, and that no facts of importance would be thereby neglected.

CHEMISTRY

LONDON PROGRAMME FOR SESSION 1924–5

Of Ordinary Meetings of Chemical Interest

Times and places of Meetings with topics for discussion will be notified by the respective Societies

SOCIETY OF CHEMICAL INDUSTRY

MEETING OF COUNCIL

The monthly meeting of Council was held on October 10, 1924, the President (Mr. W. J. U. Woolcock, C.B.E.) in the Chair. The President extended a cordial welcome to the new members of Council who were present.

Intimation was made of the death of Mr. W. R. Bird, recently elected Chairman of the South Wales Section, and it was reported that Mr. George H. Clegg, of Cardiff, had been appointed his successor.

A discussion took place on the falling off in applicants for membership and methods for obtaining new members were decided upon. As a means of attracting such it was agreed that no Entrance Fee shall be paid by members elected during 1925.

A letter from the Swedish Federation of Chemical Industries was read (see *Chemistry and Industry*, August 22, 1924), suggesting the adoption of the name "Methanol" as a substitute for "Methyl Alcohol," owing to the poisonous properties of the substance and possible confusion of it with Ethyl Alcohol. The suggestion was adopted on behalf of the Society.

The President and Sir Wm. Pope were nominated delegates to attend the celebration of the Coming of Age of the University of Leeds, and the Jubilee of the Yorkshire College in December.

On the invitation of the Dutch Chemical Society, the President was nominated to represent the Society at the Jubilee of the Foundation of Stereo-Chemistry laid by van't Hoff and Le Bel to be held in Amsterdam on October 25.

Mr. E. V. Evans was nominated delegate to the Smoke Abatement Conference in Manchester in November.

Permission was given to the Sydney Section to admit Associates on the same footing as already agreed to in Home and Canadian Sections.

Reports of various Committees were submitted, and 14 new members were elected:—Home, 8; Overseas, 6.

The arrangements for the Joint Dinner of the Society and the Chemical Industry Club in November were reported.

The following Committees were re-elected:—

House Committee: The President, Hon. Treasurer, Hon. Foreign Secretary, Mr. J. L. Baker, Dr. Wm. Cullen, and Prof. J. W. Hinchley.

Representatives on the Bureau of Chemical Abstracts: Dr. E. F. Armstrong, Mr. J. L. Baker, Mr. E. V. Evans, and Sir Wm. J. Pope.

Publications (*Transactions*) *Committee*: Mr. J. L. Baker, Mr. W. H. Coleman, Prof. J. W. Hinchley, Dr. W. R. Hodgkinson, Mr. E. Grant Hooper, Mr. W. F. Reid, and Mr. W. G. Wagner.

The next meeting of Council will be held on Friday, November 14, 1924, at 2.30 p.m.

SUSPENSION OF ENTRANCE FEE

As an inducement [illegible] chemists to become members, the Council has r[illegible] that no entrance fee shall be [illegible] members [illegible] the Society in 1925.

A form of application for membership will b found at the end of this section, and it is hope that it may be used to introduce a new member fo next year.

NOTTINGHAM SECTION

At the meeting held on October 8, Mr. W. J. U Woolcock, C.B.E., delivered an address on "Publicit in Chemical Industry," which was illustrated by th exhibition of two kinematograph films, "Coal and its Products" and "Heavy Chemicals," which wer much appreciated by the audience. A summar of Mr. Woolcock's address is given below:—

The growth in the practice of publicity in thi country has been so gradual that we have hardl noticed it. Only when we look back over a numbe of years do we realise what an enormous develop ment has taken place and how it has affected ever phase of our daily life. Every man, every firm, ever Association or Society, lives on his or its reputatio The Society loses its members, if it loses its reputatio for doing good work. The firm loses business as soo as its customers think it of poor repute. The ma makes no progress in his work unless he has th reputation for doing it well. Publicity is the agenc which makes reputation. Hence its importance i every industry, and in particular in chemical industry

I like to think of the days when there were n newspaper advertisements and no shop windows When the merchant and the tradesman were entirel dependent on the word-of-mouth recommendatio of their customers, and where their personal reputa tions were made by the publicity which came fron street corner or tavern conversations.

Then came the daring fellow who removed th discreet perforated zinc window blind which hid hi goods from the vulgar gaze, and boldly placed hi goods in the shop window. He was inevitabl considered a low person, but he possessed the essenti factor to success in publicity, that is, enthusiasm In the joint enterprise in which you and I are engage of building our Society we have to remember thre things:—

(1) The Society's existence depends on its reputa tion.

(2) Unless we give publicity to its work we canno build up its reputation.

(3) Enthusiasm for the work of the Society an enthusiasm in giving it publicity is essenti to our success.

But let us return to the enthusiast who started th shop-window publicity. I imagine as soon as hi example was followed, he thought of the possibilit of an advertisement in a newspaper, and I have wit me some reproductions of old copies of the *Tim* which were printed at Wembley, and which giv some idea of the restrained tone of the advertisement

Later in development came the displayed adve tisement with a carefully written-up article in th text of the paper. About the same time the use c the correspondence columns developed. At one tim the letters to the editor expressed the feelings of th readers of the paper. Righteous indignation agai

the Government—any Government—protests against oppression in all its forms, suggestions for the better conduct of every department of public life. In fact nothing but genuine expressions of feelings which could not be kept under. The advertiser to some extent gauged the popularity of a paper by the amount in its correspondence columns. This led to the stimulation of these columns, sometimes I fear by letters written by friends of the staff. Then came the beginning of publicity as we know it to-day; the realisation that "publicity" was "reputation," and that no cause could hope to obtain adherents, no industry could ultimately prosper unless in the eyes of the public it had reputation. This required a much more specialised treatment. The letter to the editor and the plain advertisement fell into disrepute and in their places came the use of "News" items. Let me illustrate what I mean by a wholly fictitious case. Suppose a branch of the industry is devoted to the manufacture of what I will call methauin products, and the production has reached a stage where the proprietors either want more capital or they want protection against foreign competition, or to increase their sales. We shall find all sorts of little paragraphs appearing as to the firm producing it. A wedding in the family of the proprietor will be recorded. A dinner of the directors and staff or an outing of the workpeople is written up—always with the name of the product well to the fore. An accident outside the works can always be utilised as "News." In other words a steady flow of news keeps the product before the general public. The art of poster publicity is now developed to an extraordinary and sometimes beautiful extent. I show one of the posters connected with the Exhibition. This brings me to the publicity of an industry in contradistinction to that of a firm. We have now realised that much can be done for individual firms in an industry by developing the public reputation of the industry itself.

A few years ago if you had casually touched a man on the shoulder and said one word—"chemicals" to him, and then asked him what was the first word that came into his mind, he would have said "Germany." It has been my ambition to change that, and so arrange the publicity of the industry that the reputation of the industry should be in everybody's mind. To this end there have been wireless talks, which, as you know, cannot be used for advertising any particular article or firm but can tell the people something about an industry. Then we had two films which will be shown you in a minute. These films were not designed for such an audience as this but for the public, and they are being shown in cinematograph theatres all over the country.

I now turn to the last method I shall mention of building up the reputation of an industry, that of exhibitions, and I shall refer to three types. In the first type I instance an exhibition for the lay mind. When the Safeguarding of Industries Bill was before the House of Commons, I found that a large number of my colleagues had but little knowledge of the substances which were dealt with in the Schedule of the Act. We, therefore, arranged an exhibition of fine chemicals, and their every-day applications. The exhibition was not open to the public, but we allowed the Press to visit it. Its scope of usefulness was limited, but it achieved exactly what we aimed at.

The second type of exhibition is to be found in the British Industries Fair. It is a purely trade exhibition, designed to attract buyers of chemicals. This does not necessitate a very attractive display, nor is it necessary to interpret the technical features.

The British Empire Exhibition, however, furnishes an excellent example of the third type of exhibition at which, although exhibitors hope to receive business inquiries or even to make sales, they realise that in the main they are spending their money on publicity. It is interesting to note how much good publicity is made by all small items. A fact, for example, that the Chemical Hall at Wembley occupies 40,000 sq. ft. and not 37,000 sq. ft. has been an advantage. It is the largest of the sections in the Palace of Industry, and because of being slightly larger than several other sections is always mentioned first. The fact that it is entered by a gate that is the called the "Alchemist Gate" is a trifle which has brought a good deal of publicity.

That the section has been prolific in good stories has also had its effect. One concerning an innocent German, who insisted on keeping his hat in one hand during the time he was allowed to hold a bottle of Perkin's Mauvein in the other has provided excellent copy. An accident at one of the stalls not only provided more copy but gave us a coat of blue paint on the roof and added to the comfort of the section during the short spell of warm weather which we had early in the year. On Sunday, when the sun's rays were breaking through the glass roof of the Chemical Hall, a large glass-covered dish, which was reputed to contain two million tuberculous bacilli burst with the heat. A mere hint to the Press representatives as to the possible effect of this accident was sufficient to secure a coat of blue paint which nothing else was able to do. I might add that the glass dish was only supposed to contain the germs.

The Chemical Section at Wembley, as I have stated, was designed to attract the notice of the public, and some millions of people have been through the Chemical Hall. The Scientific Section had a more limited appeal. Before a number of the public could be attracted to this part of the Chemical Hall there had to be some desire on the part of the visitor to know something about science, but it was a revelation to the organisers of the section how interested very large numbers of the general public were in everything connected with Science. Having satisfied that interest, it was quite easy to dispose of about 10,000 pamphlets following the different branches of science and written in popular language. The total cost of the Chemical Hall was rather over £100,000, roughly about 0·05 per cent. of the amount invested in chemical industry in this country.

One could say without fear of contradiction that the general public to-day is proud of its British Chemical Industry, and has begun to know and appreciate something of the work of its scientific chemists. I want to enlist the assistance of the branches of the Society in making still more widely known the work of its members.

CORRESPONDENCE

THE EARLY HISTORY OF ANTIMONY

Sir,—In his interesting article on "The Early History of Antimony," Dr. Hyman gives the date of "Basil Valentine's" book, "The Triumphal Chariot of Antimony," as 1624. It is perhaps not well known that the book first appeared in German in 1604, with the title: "Triumph Wagen Antimonii, Fratris Basilii Valentini, Benedicter Ordens, . . . publiciret und am Tag geben durch Joahann Thölden, Hessum, mit einer Vorrede Doctoris Joachimi Tanckij, Prof. in Univ. Leipz., Leipzig, Apels, 1604. (64 pp.) The Latin translation by Kerkringius appeared in 1671, and the illustration in the article is from this edition. The part played by Tanckius in the preparation of the book has not, so far as I know, been elucidated. It is generally regarded as a forgery by Thölde, the "editor"—if editors can be said to forge anything!

I may mention incidentally that James's "Medical Dictionary," a work filling three enormous volumes, contains many interesting notices on the history of chemistry.—I am, Sir, etc.,

J. R. Partington

East London College
October 10, 1924

CHEMICAL PUBLICATIONS

Sir,—It is only after severe mental travail that I have overcome a certain timidity in venturing to approach the fane of your stateliness.

I am not an ornithologist, and may be mistaken in supposing that the wren will fight to defend her young; but if she does so, it will be conceded that the heart of the wren militant must be wrung by conflicting emotions. Those emotions, Sir, are but as an ineffable calm when compared with my present feelings. Despite my timid nature, I feel impelled to resist an attack, although, unlike the wren, I am not actuated by the parental instinct.

The attack to which I refer takes the form of a bolt launched from a locality not 100 miles from Yorkshire, followed by a second bolt from the same locality aimed at the same target. A single shaft might have been condoned as accidental; the loosing of the second definitely establishes hostile intent, and has reduced me to a state of mind which I, being a chemist and therefore unable to write my own (or any other) language, am impotent to describe.

Although the bow has thus been drawn in such a remote locality, it has by no means been drawn at a venture. The target, Sir, is no less than a distinguished and useful society, a society devoted to the pursuit of pure science, as distinguished from science tainted with utilitarianism. That a society of this character should be dear to all chemists may be taken as axiomatic. Only stateliness such as yours, Sir, can bear with equanimity the news that it is from the hands of chemists that the hostile arrows have been sped. One is, at first, tempted to designate such treachery as "savage jealousy," but there is a double *entendre* which may explain their motives. While the society [illegible] am sure, dear to all chemists, to some chemists, Sir (and to this category belong our archers), the society is too dear. The world will, fortunately for its peace of mind, never know to what an extent my affection and esteem for a venerable society were wounded when, from a blue that in its serenity rivalled your own stateliness, those fell bolts descended. To you, as to a firm rock, I now look in this time when all my conceptions have been so rudely shaken. What I took for contented appreciation (I allude to the literary status of the society's publications) seems to have been ill-disguised tolerance. The eagerness with which the pages of those publications were scanned turns out to have been the impatient zest of the treasure hunter, which gives place to recriminations if the expected treasure is not forthcoming. Little treasure has, it would appear, been carried in the pages which have reached Yorkshire.

One criterion of works of literary merit is that they can—nay, must—be read and re-read. Literary pearls must often be dived for, and it is, I believe, R. L. Stevenson who emphasises that more joy lies in the quest than in the actual discovery. The *Journal* of the society in question, if a timid man may venture to assess a journal of such eminence, is a work of literary merit. Rarely, if ever, does the writer manage to skim the full cream of that journal in a single effort. To skim cream from some sections he has made repeated attempts, in not a few cases (tell it not in Gath) signally failing. It may be timidity which deters me from concluding—because I have failed in those cases to extract cream—that cream is absent. A conclusion of this nature, however, might possibly be drawn in a certain county which you might succeed in naming.

I have hitherto derived much innocent pleasure from my never-ending quest for cream, and Stevenson's words have consoled my all too frequent failures. In fact, I have lived for the quest. At intervals I receive my consignments of chemically prepared milk, the joys of skimming which are scarcely beginning to pall when the next delivery arrives. The following are examples of contributions which have given me the pure pleasure of the quest (to the entire exclusion, be it added, of the baser pleasure of discovery):—

(*a*) 4-Nitro-2-sulphophenyldehydrothio - *p* - toluidine sulphonic acid.

(*b*) Catalytic Racemisation of the Diastereoisomeric l - Menthyl Phenylbromoacetates.

(*c*) Action of Chlorine on 5-Chloro-1 : 1-dimethyl-Δ^4-cyclohexen-3-one.

It may seem invidious to single out these *inter pares*, but I feel that the thrills these items afforded me were not experienced by our archers.

Less timid minds than mine, Sir, have quailed at the idea of setting a money value on æsthetic pleasure. Such minds are now to be found in Yorkshire. The conclusion reached by these minds is that an upper limit can be defined to the possible values of the pleasures which I have so greatly enjoyed. That upper limit is not greater than £3 sterling per annum.

It has been said that a Jew chasing a Scottish debtor illustrates perpetual motion. I am neither Jew nor Scot, yet to me also £3 is (or are) £3. I

would perish rather than forego the pleasure I have been deriving as the result of spending that sum annually in a certain way, were it not for the fact that I was born, Sir, in Yorkshire. The modesty characteristic of that country dissuades me from claiming the *nom-de-plume* "Eboracum," which I feel sure would carry weight in certain quarters, but I feel also that in those quarters no need will be felt for the moral support of that admirer of your stateliness, Sir, who begs to sign himself,—Yours, etc.,

London J. W. Farmery
October 12

PERSONAL AND OTHER ITEMS

Mr. J. D. Mounsey has been elected Master of the Feltmakers' Company, Mr. P. H. Hirley of the Founders' Company, Mr. J. Lusty of the Loriners' Company, Mr. B. P. Thomas of the Glaziers' Company, and Mr. W. W. Leuchars Prime Warden of the Dyers' Company.

Messrs. W. B. Cooke and S. L. B. Etherton have been appointed to research assistantships in mining and fuel, respectively, in the University of Sheffield.

The German Institute for the Fermentation Industry recently celebrated the fiftieth anniversary of its foundation.

Sir W. Jones, chairman of the research committee of the British Refractories Association, is at present on a visit to the United States.

A special course of lectures in the Manchester College of Technology is to be held on "The Chemistry and Technology of Painters' Oils, Colours and Varnishes." The course, which begins on October 22, is held on Wednesdays from 7.30 to 8.30.

Sir Max and Lady Muspratt have returned to Liverpool from Canada.

The President of the Board of Education has appointed a Departmental Committee to consider what changes, if any, are required in the constitution of the University of London.

Mr. W. L. Helm, vice-chairman of John Knight, London, Ltd., has been appointed a managing director of Lever Brothers, Ltd.

Mr. J. B. M. Herbert has been appointed assistant lecturer in chemistry in the University of Manchester, in place of Mr. E. L. Hirst, who becomes lecturer in chemistry at Armstrong College, Newcastle-on-Tyne.

Sir William Alexander, chairman of the British Dyestuffs Corporation, has left Southampton by the R.M.S. *Mauretania* for New York.

On October 1, Sir William Bragg opened the new college of pure science in the University of Durham, afterwards receiving the honorary degree of D.C.L.

We regret to announce that Prof. G. D. Liveing is suffering from a fractured hip owing to being knocked down by a bicycle in Regent Street, Cambridge. Prof. Liveing is going on well, considering his 97 years.

Dr. R. Escales, founder of the "Zeitschrift für das gesamte Schiess- und Sprengstoffwesen," and of "Kunststoffe," a journal devoted to the technology of artificial textiles, died in September aged 61.

Canadian Nickel Industry

The British American Nickel Co. is stated to have gone into liquidation. The Murray mine and smelter, near Sudbury, Ont., and the refinery at Deschenes, Quebec, near Ottawa, have closed down. The company employed 700 men at Sudbury, and about 500 at the Deschenes plant. The British Government has a financial interest in the company. The failure is attributed to the inability of the Norwegian interests to render financial assistance.

Smoke Abatement Exhibition

The Smoke Abatement Exhibition to be held in Manchester in November next will include large gas and electrical displays, and will be representative of firms interested in the abatement of both industrial and domestic smoke. It is expected that a very large number of delegates from the municipalities and various institutions will be present at the Conference held in connexion with the Exhibition, when papers will be read on the production of smokeless fuel by the low-temperature carbonisation of coal, the use of town and producer gas in industry, mechanical stokers, domestic appliances, pulverised-fuel firing, oil firing, and the effects of smoke on health, building materials, and other subjects. A special feature will be the "Ideal Boiler House," which is being designed to illustrate how fuel economy and smoke abatement can be achieved by attention to the method of firing and the setting of a boiler. Information can be obtained from Mr. C. Elliott, B.Sc., A.M.Inst. C.E., Hon. Secretary, the Smoke Abatement League of Great Britain, 33, Blackfriars Street, Manchester.

Labour Problem in Mining

In his presidential address at the annual meeting of the Institution of Mining Engineers held at the British Empire Exhibition, Dr. J. S. Haldane, discussing the labour problem in mining, said that the real cause of labour unrest was rebellion against what was regarded as inhuman relations. The danger arose from the idea that the employed were only units in an economic machine manipulated without real sympathy for or understanding of the worker. As collieries became larger, so the need increased for a greater realisation of the conception of comradeship and men of real human sympathy were required on the executive staff. Neither high wages nor welfare schemes would satisfy those employed in mining but only discerning and sympathetic treatment, a sense of comradeship in a common enterprise.

Cement Manufacture in the Empire

The manifold uses of cement and especially its employment for the manufacture of concrete, now so largely used to replace brick and stone, render it of no little importance that all countries should be able to obtain cement for local use at a reasonable cost. In many overseas countries, particularly those remote from the present centres of production the use of cement is greatly restricted owing to the heavy cost of shipment and the consequent high

price of imported supplies. Portland cement is already being made in large quantities in several countries of the Empire, such as Canada, the Union of South Africa, Australia, New Zealand, and India, whilst operations on a smaller scale are being carried on in the Sudan, Rhodesia and Malaya. It seems probable that the raw products required for cement manufacture exist in nearly all parts of the Empire, but hitherto little information has been available regarding the possibilities of establishing a cement industry in most of the Crown Colonies and Protectorates. Considerable attention has been devoted to this question in recent years by the Imperial Institute, where a fully equipped cement-testing laboratory has been installed, and raw materials have been investigated from several localities, including Nigeria, Nyassaland, Kenya, India, Ceylon, Fiji, Jamaica, and Newfoundland. The current number of the *Bulletin* of the Imperial Institute contains an article discussing this important problem, particularly in relation to the possibilities of making cement in West Africa, Nigeria, Sierra Leone and Western Togoland. The article should be read by those interested in the manufacture of cement within the British Empire.

New British Chemical Standard Steel

Messrs. Ridsdale and Co. announce the issue of British Chemical Standard Carbon Steel "E" (B.O.H.) having the following standardised figures: Carbon, 0·114 per cent., and manganese, 0·492 per cent. This material has been specially prepared to meet the need for a widely recognised carbon (colorimetric) standard above 0·10 per cent., which is near to the maximum usually desired in tinplate manufacture. It has the additional convenience of being a low manganese standard, so that those who prefer to determine the carbon (colour) and manganese from the same proportion of sample may do so. As is usual, the analysis has been conducted by a number of independent analysts, works' chemists, and others (including the United States Bureau of Standards, Washington) representing different interests.

Bottles of standard turnings may be obtained from Headquarters, 3, Wilson Street, Middlesbrough, at a fee estimated to be sufficient to cover the cost of preparation. Three sizes are now provided viz., 500 gram, 100 gram, and 50 gram. A certificate giving the names of the analysts co-operating, the types of methods used (including numerous notes) and a detailed list of the individual analyses will be supplied with each bottle.

Diamond Jubilee Celebration of the L. M. & S. Railway Chemical Laboratory, Crewe

The sixtieth anniversary of the establishment of the L.M. & S. Railway Chemical Laboratory at Crewe (the first Railway Chemical Laboratory in the country) was celebrated by the staff (past and present) at a dinner held at Crewe on October 10. Captain Beames, M.I.C.E., the principal guest, and Dr. Lewis Dale, who was in the Chair, spoke of the [illegible] of the old L. & N.W. Railway in recog-[illegible] as 1864 the importance of the application of chemical science to industry.

REVIEW

Coal Carbonization. By H. C. Porter, M.S., Ph.D. American Chemical Society, Monograph Series. Pp. 442. New York: The Chemical Catalog Co., Inc., 1924. Price $6.

Although the carbonisation of coal is a branch of chemical technology that attracts an ever-increasing interest and inspires a rapidly growing literature, the author need make no apology for the book under review. By his early association with the experimental station of the U.S. Bureau of Mines, and later experience, he is well qualified to deal comprehensively with the subject, giving due weight to the scientific aspects as well as the industrial technique.

He opens with an introductory survey discussing the *raison d'être* of carbonisation in its various modifications, the advantages and the limitations which economic considerations set to the carbonisation of fuel. The different systems are compared. The scope of carbonisation processes is limited by the profitable disposal of all the products, and for this reason he thinks the towns' gas industry is "destined to become the largest exponent of coal carbonisation" because the metallurgical coke market has not the same prospects for expansion.

Two chapters are devoted to the chemistry of coal carbonisation, including the special treatment of the nitrogen and sulphur compounds. Then several chapters on coke-oven practice follow, starting from the preparation of coal for the oven and including the purification of gas and the recovery of by-products. This constitutes the main part of the book. It must be remembered that the author writes primarily of the American, which differs materially from European practice. None the less, this is, for British coke-oven men, one of the most valuable and interesting parts of the book. Although by-product coking was initiated in Europe, there is no doubt that of recent years the industry has developed more rapidly both in range and technique in America. In the nature of things, coke-oven experiments are expensive, and economic conditions are such that America is better able to embark on bold and costly innovations in large-scale practice. That is all the more reason why this book may be commended to British coke-oven workers, for modern American practice is here brought to a focus as nowhere else.

There is a long chapter on carbonisation for towns' gas, which covers ground where America has less to teach, and indeed has followed rather than led. The author is well acquainted with modern practice, but in dealing with steaming does not seem to have made the best use of available material. The report on experiments on the steaming of vertical retorts, initiated by the Institution of Gas Engineers, is not even mentioned.

The subject of low-temperature carbonisation, which in the author's opinion "has not attained or given assurance of attaining in the future such commercial success as to warrant assignment to a principal rôle," is dealt with in a chapter containing descriptions of a number of processes which have come before the public. Here considerable space is devoted to the ingenious Piron and Caracristi process

now attracting so much interest, but though estimates of cost are given, it is not made clear how far commercial success has been attained.

Prof. S. W. Parr has written an admirable introduction to the book which might fittingly have been reproduced as a review. The reviewer has no hesitation in recommending students and practitioners of coal carbonisation to seek in the perusal of this book both pleasure and profit.

H. J. HODSMAN

PARLIAMENTARY NEWS

HOUSE OF COMMONS

The Proposed German Dyestuffs Agreement

In a written reply to Mr. Graham White, who asked about the proposed agreement between the Interessen-Gemeinschaft and the British Dyestuffs Corporation, Mr. Sidney Webb stated that the Board of the British Dyestuffs Corporation had been informed that the Government would feel compelled to exercise their power of veto with respect to an agreement with the Interessen-Gemeinschaft on the lines suggested.—(Oct. 8.)

COMPANY NEWS

BRITISH GLUES AND CHEMICALS, LTD.

Presiding over the annual meeting, the chairman, Mr. T. Walton, said that during the past year, although raw materials had increased in cost, the company had slightly increased its output, and had by energetic salesmanship sold its increased production, so that stocks were now down, both in value and in weight. The steady expansion of the company's foreign markets was particularly encouraging. The company had, during the year, introduced to the market two new cattle foods, which had been well received by the agricultural community. Research work was going forward, the intention being to increase efficiency in manufacture and to find new uses for the company's products.

GLENBOIG UNION FIRECLAY CO., LTD.

The net profit of the company for the past year, including £10,155 brought forward, was £23,410. A dividend is recommended of 15 per cent. for the year, less tax, payable on October 27, carrying forward £5973. A sum of £10,872 was expended on repairs and renewals, and was paid out of revenue. The capital expenditure during the year was £1532.

BRITISH CYANIDES CO., LTD.

The report for the year ended April 30 last shows a loss of £24,991. From £14,847 brought forward from last year, there has to be deducted the interim dividend on the preference shares paid on December 15 1923, leaving £13,423 to be set against the loss made during the period under review and leaving a balance of loss to be carried forward of £11,568. The sum of £43,696 has been charged against reserve account, being the cost of the shares in the British Potash Co., Ltd., in liquidation, which are now of no value. The position and prospects of the company have greatly improved during the past few months.

BROKEN HILL PROPRIETARY CO., LTD.

The year ending May 31, 1924, is the first financia period since the establishment of the Steel Works a Newcastle that continuity of operations in all depart ments has obtained. The output from th Newcastle Works in 1924 was as follows, figure for 1923 being given in parentheses:—Pig iron 306,258 tons (62,334 t.); Steel ingots, 284,669 t (52,810 t.); coke, 305,084 t. (66,790 t.); sulphat of ammonia, 4545 t. (1071 t.); tar, 3,574,341 gals (706,148 gals.). In 1924, during 6½ months working 36,392 t. of ore was produced; 34,862 t. of crude or and tailings was treated, and 2158 t. of lead concer trates was produced. In the slimes flotation plar (Bradford Process), during 1924, 117,336 t. of slime were treated, and 12,011 t. of lead concentrate and 25,464 t. of zinc concentrates were produced The net profit for the period under review amounte to £279,339 2s. 2d., after providing £299,12 for all depreciation. The company has obtaine re-assessments of income tax for past years, and wa able to reduce the provisional amount held in reserv in Sundry Creditors' Account for this purpos The sum of £100,000 has been restored to Reserv Fund which now stands at the old figure of £1,500,00 and liquid assets total £1,030,684 7s. 7d. Productio during the year amounted to 305,084 t. coke, 3,574,34 galls tar and 4545 t. ammonium sulphate. Th plant for the manufacture of benzol, toluol an solvent naphtha has worked satisfactorily, 773,95 galls. motor spirit and 52,918 gall. solvent naphth being produced. A subsidiary company styled th B.H.P. By-Products Co. Pty., Ltd., was forme to acquire the tar distillation plant of Messr De Meric, Ltd. This new company had a successfu year and absorbed the whole of the output of ta from the coke ovens. Another new compan styled the B.H.P. Collieries Pty., Ltd., was forme during the year to develop coal-bearing land whic had been secured in the Maitland district, and commencement has been made with this work.

CANADIAN EXPLOSIVES, LTD.

The dividend of 1¾ per cent. for the quarter ende September 30 on the Seven per cent. cumulativ preferred shares is payable on October 15, to share holders on record September 30.

LAUTARO NITRATE CO., LTD.

A third interim dividend of 5 per cent. for th year 1924 has been declared, payable on October 2 to shareholders registered at the closing of th books on October 20, and to holders of share warra to bearer coupon No. 57. No dividends were pai for the previous four years, but in 1923 capitalised bonus of three new shares for eve seven held was distributed. The company recentl acquired the Lastenia Nitrate Company.

BRYANT AND MAY, LTD.

A dividend of 7 per cent. less tax, for the hal year ended September 30, 1924, has been declare on the preference shares, and an interim divide of 4 per cent. free of tax on ordinary and partnershi shares, payable November 1.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech. ..	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder..	£47 per ton.
Acid Hydrochloric ..	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali.. ..	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder ..	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder..	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Copper Sulphate	£25 per ton.
Methylated Spirit 64 o.p.—	
Industrial	2s. 7d.—2s. 11d. per gallon, according to quantity.
Mineralised	3s. 8d.—4s. per gallon, according to quantity.
Nickel Sulphate	£38 per ton d/d. Normal business.
Nickel Ammon. Sulphate	£38 per ton d/d. Normal business.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate ..	5½d. per lb.
Potass. Chlorate.. ..	3d.—4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake..	£3 10s. per ton d/d.
Soda Caustic, solid ..	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton, carr. paid.
Sod. Bichromate.. ..	4½d. per lb.
Sod. Bisulphite Powder 60/62%	£17—£18 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
[illegible]	3d. per lb.
[illegible] 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
[illegible] conc. 60/65	About £14 10s. per ton d/d.
[illegible]t. ..	£9 per ton d/d.
[illegible] Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	6½d.—1s. 2d. per lb., according to quality.
Crimson	1s. 4d.—1s. 6d. per lb., according to quality.
Arsenic, Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide ..	3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide ..	£30—£33 per ton, according to quantity.
Carbon Black	7d.—7½d. per lb. ex wharf.
Carbon Tetrachloride ..	£60—£65 per ton, according to quantity, drums extra.
Chromium Oxide, green..	1s. 3d. per lb.
Indiarubber Substitutes White and Dark ..	5d.—9½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	£48 per ton, barrels free.
Lead Hyposulphite ..	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£16 5s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Precip. B.P. ..	£47 10s.—£52 10s. per ton, according to quantity.
Sulphur Chloride ..	4d. per lb., carboys extra.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep ..	5s. 1d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

Acetate of Lime—	
Brown	£12 per ton.
Grey	£16 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 15s.—£9 5s. per ton, according to grade and locality.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. „ „ 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 9d. per gall. Unrefined.
Wood Naphtha—	
Miscible	4s. 10d. per gall. 60% O.P.
Solvent	5s. 3d. per gall. 40% O.P.
Wood Tar	£4 5s. per ton.
Brown Sugar of Lead ..	£43 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	6¼d.—6½d. per lb. Quiet.
Crude 60's	1s. 7d.—1s. 9d. per gall, according to district. Market flat.
Acid Cresylic, 97/99 ..	2s.—2s. 1d. per gall. Demand fair.
Pale 95%	1s. 9d.—2s. 1d. per gall. Better enquiry.
Dark	1s. 9d.—2s. per gall. Fairly steady.
Anthracene Paste 40% ..	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	6½d.—6¾d. per gall. Small demand
Unstrained	6d.—6½d. per gall.
Benzole—	
Crude 65's	7½d.—9d. per gall. ex works in tank wagons.
Standard Motor ..	1s. 1½d.—1s. 3d. per gall. ex works in tank wagons.

Benzole—	
Pure	1s. 5½d.—1s. 7d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5d.—1s. 5½d. per gall. Small demand for home consumption.
Pure	1s. 8d.—1s. 9d. per gall. Small demand for home consumption.
Xylol coml.	1s. 9d. per gall. Prices reduced.
Pure	2s. 3d. per gall. Prices reduced.
Creosote—	
Cresylic 20/24% ..	8½d. per gall. Little demand.
Middle Oil .. .. / Heavy Oil .. .. / Standard Specification	5d.—6½d. per gall., according to quality and district. Fair business passing. Small demand from America.
Naphtha—	
Solvent 90/160 ..	11d.—1s. per gall. Demand good.
Solvent 90/190 ..	11d.—1s. per gall. Fair inquiry.
Naphthalene Crude—	
Cheaper in Yorkshire than Lancashire. Demand rather better.	
Drained Creosote Salts	£4—£6. Quiet.
Whizzed or hot pressed	£6—£9 per ton.
Naphthalene—	
Crystals and Flaked ..	£12—£15 per ton, according to district.
Pitch, medium soft ..	40s.—45s. per ton f.a.s. Market very flat.
Pyridine—90/160 ..	18s. 6d.—19s. per gall. Steady demand.
Heavy	12s. per gall. Market dull.

INTERMEDIATES AND DYES

Business in dyestuffs has again been better this week, and users seem to have more confidence.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% ..	1s. 7d. per lb.
Acid H.	3s. 11d. per lb. 100% basis d/d.
Acid Naphthionic ..	2s. 2d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech. ..	1s. 1d. per lb. Improved demand.
Acid Sulphanilic ..	9½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	8d. per lb. naked at works.
Aniline Salts	8½d. per lb., naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	4s. per lb. 100% basis d/d.
Benzyl Chloride 95% ..	1s. 1d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C. ..	4½d. per lb. Rather quiet.
m-Cresol 98/100% ..	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C. ..	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	3s. per lb.
Dichloraniline S. Acid ..	2s. 6d. per lb. 100% basis.
p-Dichlorbenzol	£85 per ton.
Diethylaniline	4s. 6d. per lb. d/d., packages extra, returnable.
Dimethylaniline	2s. 3d. per lb. d/d. Drums extra.
Dinitrobenzene	9d.—10d. per lb. naked at works.
Dinitrochlorbenzol ..	£84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine	2s. 10d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. per lb. d/d.
α-Naphthylamine ..	1s. 4d. per lb. d/d.
β-Naphthylamine ..	4s. per lb. d/d.
m-Nitraniline	4s. 3d. per lb. d/d.
p-Nitraniline	2s. 3d. per lb. d/d.
Nitrobenzene	5½d.—5¾d. per lb. naked at works.
o-Nitrochlorbenzol ..	2s. 11d. per lb. 100% basis d/d.
Nitronaphthalene ..	10½d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine ..	3s. 11d. per lb. d/d.
p-Phenylene Diamine ..	10s. 2d. per lb. 100% basis d/d.
R. Salt	2s. 5d. per lb. 100% basis d/d.
Sodium Naphthionate ..	2s. 3d. per lb. 100% basis d/d.
o-Toluidine	10d. per lb.
p-Toluidine	2s. 10d. per lb. naked at works.
m-Toluylene Diamine ..	4s. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P. ..	£47 per ton. Firmer.
Acid, Acetyl Salicylic ..	3s. 1d. per lb., according to quantity. Sales steady. Price firm.
Acid, Benzoic B.P. ..	3s. per lb.
Acid Boric B.P.	Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 3½d.—1s. 4½d. per lb., less 5% for ton lots. Market very weak.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst. ..	6s. 9d. per lb. Resublimed quality 8s. per lb. Market firm.
Acid Salicylic	1s. 6d.—1s. 8d. per lb., according to quantity.
Acid, Tannic B.P. ..	2s. 10d. per lb. Market quiet.
Acid, Tartaric	1s. 1½d. per lb. less 5%.
Amidol	9s. per lb. d/d.
Acetanilide	2s. per lb. for quantity. More enquiry.
Amidopyrin	16s. 6d. per lb. for spot stocks.
Ammon. Benzoate ..	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate ..	12s. 6d. per oz. for English make.
Barbitone	14s. 3d. per lb. Cheaper.
Bismuth Carbonate ..	10s. 6d.—12s. 6d. per lb.
" Citrate	10s. 3d.—12s. 3d. "
" Salicylate ..	9s.—11s. "
" Subnitrate ..	8s. 8d.—10s. 8d. "
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	Market firm.
Ammonium	1s. 6d.—1s. 9d. per lb. According to quantity.
Potassium	1s. 4d.—1s. 7d. per lb. According to quantity.
Sodium	1s. 5d.—1s. 8d. per lb. According to quantity.
Calcium Lactate ..	1s. 6d.—1s. 9d. per lb., according to quantity. Fair demand and steady market.
Chloral Hydrate	4s. per lb. Market easier after recent firmness.
Chloroform	2s. per lb. for cwt. lots. Very steady.
Formaldehyde	£49 per ton.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free ..	7s. per lb.
Glycerophosphates—	
Iron	8s. 9d. per lb.
Magnesium	9s. per lb.
Potassium, 50% ..	3s. 6d. per lb.
Sodium, 50%	2s. 6d. "
Guaiacol Carbonate ..	10s. per lb.
Hexamine	3s. 1d.—3s. 3d. per lb.
Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor ..	English make offered, 120s. per oz

Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. ,,
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£25 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst, B.P.	55s. per lb. Price shows signs of recovery.
Synthetic	26s.—35s. per lb., according to quantity. English make. Increasing demand.
Mercurials	Market very quiet.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	3s. 6d.—3s. 7d. ,,
White precip.	4s. 7d.—4s. 8d. ,,
Calomel	3s. 11d.—4s. ,,
Methyl Salicylate	1s. 10d.—2s. per lb. Seasonal increase in demand.
Methyl Sulphonal	24s. per lb. Slightly weaker.
Metol	11s. per lb. British make.
Paraformaldehyde	2s. 8d. per lb. for B.P. quality.
Paraldehyde	1s. 4d.—1s. 6d. per lb. in free bottles and cases. Supplies plentiful.
Phenacetin	5s. 9d. per lb.
Phenazone	7s. per lb.
Phenolphthalein	5s. 6d.—6s. per lb.
Potass. Bitartrate—	
99/100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots.
Potass. Citrate	1s. 10d.—2s. 2d. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Steady market.
Potass. Metabisulphite	[illegible] per lb., 1-cwt. kegs included. f.o.r. London.
Potass. Permanganate	7½d. per lb. spot. Forward prices higher.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Saccharin	63s. per lb., in 50-lb. lots.
Salol	3s. 6d.—4s. per lb.
Sod. Benzoate, B.P.	2s. 6d. per lb.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite—	
Photographic	£13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	75s.—82s. 6d. per cwt., according to quantity. Quiet market.
Sod. Salicylate	Fair demand. Powder 2s.—2s. 3d. per lb. Crystal at 2s. 2d.—2s. 5d. per lb. Flake 2s. 6d. per lb.
Sod. Su[illegible]—	
Pure [illegible]	10d.—1s. 2d. per lb.
Sod. S[illegible]ate, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal	15s. 6d. per lb. Little demand.
Thymol	17s. per lb. Slightly cheaper.

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.
Aubepine	15s. 3d. ,,
Amyl Acetate	2s. 6d. ,,
Amyl Butyrate	6s. 9d. ,,
Amyl Salicylate	3s. 3d. ,,
Anethol (M.P. 21/22° C.)	4s. 6d. ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 9d. ,,
Benzyl Alcohol free from Chlorine	2s. 9d. ,,
Benzaldehyde free from Chlorine	3s. 6d. ,,
Benzyl Benzoate	3s. 6d. ,,
Cinnamic Aldehyde—	
Natural	18s. 9d. ,,
Coumarin	19s. 6d. ,,
Citronellol	17s. ,,
Citral	8s. ,,
Ethyl Cinnamate	12s. 6d. ,,
Ethyl Phthalate	3s. 3d. ,,
Eugenol	10s. ,,
Geraniol (Palmarosa)	33s. 6d. ,,
Geraniol	11s.—18s. 6d. per lb.
Heliotropine	6s. 9d. ,,
Iso Eugenol	15s. 9d. ,,
Linalol ex Bois de Rose	26s. ,,
Linalyl Acetate	26s. ,,
Methyl Anthranilate	9s. 6d. ,,
Methyl Benzoate	5s. ,,
Musk Ambrette	50s. ,,
Musk Xylol	13s. 6d. ,,
Nerolin	4s. 9d. ,,
Phenyl Ethyl Acetate	15s. ,,
Phenyl Ethyl Alcohol	16s. ,,
Rhodinol	60s. ,,
Safrol	1s. 10d. ,,
Terpineol	2s. 4d. ,,
Vanillin	25s. ,,

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.
Anise Oil	2s. 8d. per lb.
Bergamot Oil	16s. 6d. per lb.
Bourbon Geranium Oil	35s. per lb.
Camphor Oil	65s. per cwt.
Cananga Oil Java	10s. per lb.
Cinnamon Oil, Leaf	6½d. per oz.
Cassia Oil, 80/85%	9s. 9d. per lb.
Citronella Oil—	
Java 85/90%	5s. 9d. per lb.
Ceylon	3s. 3d. per lb.
Clove Oil	7s. 6d. per lb.
Eucalyptus Oil 70/75%	2s. 3d. per lb.
Lavender Oil—	
French 38/40% Esters	28s. 6d. per lb.
Lemon Oil	3s. per lb.
Lemongrass Oil	4s. 6d. per lb.
Orange Oil, Sweet	11s. per lb.
Otto of Rose Oil—	
Bulgarian	40s. per oz.
Anatolian	18s. per oz.
Palma Rosa Oil	16s. 6d. per lb.
Peppermint Oil—	
English	65s. per lb.
Wayne County	30s. per lb.
Japanese	Market practically bare.
Petitgrain Oil	9s. 3d. per lb.
Sandal Wood Oil—	
Mysore	26s. 7d. per lb.
Australian	18s. 6d. per lb.

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before Dec. 7th; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on Oct. 23rd.

I.—Applications

Bollmann. Heat-exchanging and distilling apparatus. 23,036. Sep. 30.

Cloudsley, and Lever Bros. Centrifugal separation of liquids etc. 23,081. Sep. 30.

Ellis (Ehle). Furnaces. 23,504. Oct. 4.

Fairweather (Spolka Lidowiecka Handlowo-Przemyslowa Sp. z.o.o.). Grinding and pulverising materials. 22,881. Sep. 29.

French. Furnaces. 23,172. Oct. 1.

Gardner. Apparatus for minute disintegration of substances. 22,975. Sep. 29.

Gerats. Determining critical temperatures. 23,213. Oct. 1.

Higgins. Processes involving exchange reactions. 23,183. Oct. 1.

Hooton, and Johnson and Co. Filters. 23,128. Sep. 30.

Irwin, and Johnson and Co. Filters. 23,129. Sep. 30.

Judelson. Driers. 23,496, 23,497. Oct. 4.

Morris. Pulverising or emulsifying apparatus etc. 22,947. Sep. 29.

Nyrop. Separation of particles from gases or liquids. 23,415. Oct. 3.

I.—Complete Specifications Accepted

5063 (1924). Herbst and Herbst. Mixing, kneading, and beating machine. (222,380.)

5932 (1924). Joseph. Filters for air and other gases. (222,385.)

8477 (1923). Sauer. Manufacture of adsorbent materials. (222,159.)

16,157 (1923). Peale, Peale, and Peale. Separating materials of different specific gravities. (222,185, 222,186.)

20,880 (1923). Fitzpatrick. Drying and coating porous materials for use as adsorbents and catalysts. (222,279.)

22,639 (1923). Duclaux. Membranes for ultra-filtration and dialysis. (203,713.)

464 (1924). Marks (Soc. Anon. des Produits à Flenu). Apparatus for sorting granular materials of different specific gravities. (222,361.)

6077 (1924). Pellegrino. Drying-ovens. (222,386.)

19,596 (1924). Sauer. Manufacture of adsorbent materials. (222,423.)

II.—Applications

Bertels. 23,374. *See* X.

Brown and Winser. Retorts for dry distillation of oils, tars, etc. 23,358. Oct. 3.

Ges. für Maschinelle Druckentwasserung. Preparation of raw peat to be dewatered by pressing. 23,191. Oct. 1. (Ger., 1.10.23.)

Goldstein. Treatment of hydrocarbons. 23,104. Sep. 30.

Heyl. Distillation of oil shale, coal, etc. 22,910. Sep. 29.

Hezlet. X-ray tubes. 23,208. Oct. 1.

In-Com. Gas Co., and Waldor. Fuel and means for consuming same. 22,926. Sep. 29.

Jenkins and Scott. Separating coal from shale etc. 23,293. Oct. 2.

Kidd, Pique, and Smith. 23,418. *See* XXIII.

Mitchell. External heating of vertical gas-retorts. 23,158. Oct. 1.

II.—Complete Specifications Accepted

16,956 (1923). Wood, and Minerals Separation, Ltd. Dewatering coal. (222,221.)

20,131 (1923). Imray (N. V. Silica en Ovenbouw Mij). Manufacture or treatment of coke, and manufacture of gas from coke. (222,270.)

29,008 (1923). Farbenfabriken vorm. F. Bayer und Co. *See* VII.

1193 (1924). Collin und Co. Regenerative coke ovens. (211,112.)

III.—Applications

Brown and Winser. 23,358. *See* II.

Goldstein. 23,104. *See* II.

IV.—Application

Hereward, Thomas, and Scottish Dyes, Ltd. Production of dyestuffs etc. 23,207. Oct. 1.

IV.—Complete Specification Accepted

31,990 (1923). Comp. Nat. de Mat. Colorantes et de Prod. Chimiques. *See* XX.

V.—Applications

Percival (Niederer et Cie.). Production of textile fabric with silk-like gloss. 23,201. Oct. 1.

Ross. Treatment of flax etc. 23,272. Oct. 2.

Schwalbe. Treatment of sulphite cellulose waste liquor. 23,227. Oct. 1. (Ger., 6.11.23.)

V.—Complete Specifications Accepted

7880 (1923). Tate. Converting fabrics. (221,980.)

8633 (1923). Granton. De-inking printed paper. (222,160.)

13,340 (1923). Dreyfus. Manufacture of solutions, dopes, or varnishes from cellulose derivatives. (222,168.)

17,764 (1923). Lilienfeld. Manufacture of cellulose ethers. (200,815.)

3989 (1924). Marks (Bemberg Akt.-Ges. Manufacture of artificial silk. (222,373.)

VI.—Applications

Calico Printers' Association, Ltd., and Roberts. Machines for ageing fabrics. 23,303. Oct. 2.

Calico Printers' Association, Ltd., and Roberts. Machines for wet treatment of cloth. 23,304. Oct. 2.

Standard Silk Dyeing Co. Washable dyed silk piece goods, and process of dyeing same. 23,101. Sep. 30. (U.S., 1.12.22.)

VII.—Applications

Cederberg. Manufacture of nitric acid. 23,211. Oct. 1.

Nicklin. Manufacture of ammonium sulphate and other salts. 23,161. Oct. 1.

Soc. d'Etudes Minières et Industrielles. Manufacture of nitrogen peroxide. 23,501. Oct. 4. (France, 18.9.24.)

VII.—Complete Specifications Accepted

23,567 (1923). Hartstoff-Metall Akt.-Ges. (Hametag). Producing substances from boron and carbon. (204,337.)

29,008 (1923). Farbenfabriken Vorm. F. Bayer und Co. Obtaining sulphur from gases containing hydrogen sulphide. (207,196.)

VIII.—Complete Specification Accepted

12,125 (1924). Pfalzische Chamotte-Thonwerke and Strack. Refractory bricks for blast-heaters or the like. (219,943.)

IX.—Application

Girouard. Manufacture of Portland cement. 22,945. Sep. 29.

X.—Applications

Ashcroft. Recovering tin from tin-plates etc. 23,289. Oct. 2.

Bertels and Martin. Decarbonisation of cast iron etc. 23,373. Oct. 3.

Bertels and Martin. Purification of gases for decarbonisation of cast iron etc. 23,374. Oct. 3.

Duffield. Reducing iron ore etc. from pyrites to metal etc. 23,407. Oct. 3.

Garnett and Holden. Non-corrodible alloys. 23,223. Oct. 1.

Robinson. Solder and soldering process for aluminium etc. 22,909. Sep. 29.

X.—Complete Specifications Accepted

8358 (1923). Aluminium Co. of America. Coating articles of aluminium or aluminium alloys. (212,504.)

8374 (1923). Potts (Electro Metallurgical Co.). Production of non-oxidizing non-brittle sheets of chrome iron alloys. (222,158.)

19,296 (1923). Pollak. Applying electrolytic metal coatings to porous bases. (201,567.)

XI—Application

Sachs. Anode batteries. 23,054. Sep. 30.

XI.—Complete Specification Accepted

19,296 (1923). Pollak. *See* X.

XII.—Application

Bollmann. Apparatus for removing odoriferous substances from oils and fats. 23,937. Sep. 30. (Ger., 12.6.24.)

XIV.—Applications

Bruni. Vulcanisation of rubber. 23,423. Oct. 3. (Italy, 15.2.24.)

Crick. Latex-treated materials etc. 23,179. Oct. 1.

Wiegand. Manufacture of rubber compositions. 23,003. Sep. 29.

XV.—Application

Aische and Marsh. Manufacture of size etc. 23,255. Oct. 2.

XVI.—Complete Specification Accepted

16,053 (1923). Ishitani and Kaisha. Manures. (222,181.)

XVII.—Application

Pollak. 22,952. *See* XX.

XVII.—Complete Specification Accepted

1307 (1924). Vecchis. Purifying juices and syrups in extraction of sugar from beet. (211,113.)

XVIII.—Application

Pollak. 22,952. *See* XX.

XIX.—Applications

Rees. Bleaching cereals, nuts, etc. 23,009. Sept. 30.

Stevenson. Treatment of milk. 22,934. Sep. 29.

XIX.—Complete Specification Accepted

20,047 (1923). Vogel. Manufacture of an arsenical preparation for exterminating pests. (222,268.)

25,023 (1923). Evans. Insecticide. (222,320.)

XX.—Applications

Pollak. Production of lactic acid from sugar-containing materials. 22,952. Sep. 29. (Czechoslovakia, 29.9.23.)

Riedel Akt.-Ges. Manufacture of barbituric acid derivatives. 23,112. Sep. 30. (Ger., 10.10.23.) Also 23,234. Oct. 1. (Ger., 28.6.24.)

Stephen. Manufacture of aldehydes and intermediate products. 23,136. Oct. 1.

XX.—Complete Specification Accepted

31,990 (1923). Comp. Nat. de Mat. Colorantes et de Produits Chimiques. Manufacture of perylene. (208,721.)

XXI.—Application

Godowsky and Mannes. Colour photography. 23,238. Oct. 1.

XXI.—Complete Specifications Accepted

17,138 (1923). [illegible]moto. Photographic combined developing and fixing compositions. (201,538.)

11,963 (1924). Christensen. Manufacture of multi-colour screens for colour photography. (216,853.)

XXIII.—Application

Kidd, Pique, and Smith. Determining impurities in gases. 23,416. Oct. 3.

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number:—*British India:* Ironwork, (Director-General, India Store Department, Branch No. 10, Belevdere Road, Lambeth, S.E. 1); *Cuba:* Artificial and other silk, (398); *Denmark:* Iron castings, (388); *Egypt:* Leather, (396); Leather, (B.X./1267); paint, (B.X./1271); *France:* Tinplate, copper sulphate, (389); *Italy:* Varnish and enamel paint, (390); *New Zealand:* Artificial silk, (384); *Porto Rico:* Chalmougra oil, pharmaceutical products, (399); *South Africa:* Stainless steel, (387).

Notes on Plant and Products

Pulverised Fuel.—The Vickers and International Combustion Engineering, Ltd., have contracted to supply a complete power plant utilising pulverised fuel to the York Street Flax Spinning Co., Ltd., Belfast.

Messrs. Vickers and International Combustion Engineering, Ltd., have also received a large order from Synthetic Ammonia and Nitrates, Ltd., for the boiler house for an electric power station at the Billingham-on-Tees factory. The order includes the complete equipment of the boiler house, which comprises two Thompson water-tube boilers (heating surface 9000 sq. ft., working pressure 275 lb. per sq. in.), fitted with Lopulco furnaces utilising pulverised fuel, and two Raymond roller pulverisers, each with a capacity of 6 tons of bituminous coal per hour.

Statistics in Government Publications

The Permanent Consultative Committee on Official Statistics has issued Volume II. of its annual Guide to Current Official Statistics (H.M. Stationery Office, price 1s. net, post free 1s. 4½d., pp. 306). The volume continues the detailed and systematic survey, commenced in the first issue, of the statistics contained in all current official publications. The aim of the Guide is to place the enquirer in touch with the publications containing statistics bearing on his subject, and to inform him as to the degree and mode of analysis of the statistics he will find in the volumes to which he is referred. In addition to other new features, an appendix has been added on this occasion consisting of a broad survey of publications of permanent statistical interest issued mainly since 1900.

PUBLICATIONS RECEIVED

JOURNAL OF CHEMICAL EDUCATION. Vol. I, No. 7. Pp. 137-170. Easton: Pa., The American Chemical Society, 1924.

QUALITATIVE CHEMICAL ANALYSIS OF INORGANIC AND ORGANIC SUBSTANCES. By H. W. Schimpf, Ph.G., M.D. Fourth edition, revised by A. I. Cone. Pp. ix. 201. London: Chapman and Hall, Ltd., 1924. Price 8s. 6d.

Form A.

THE

SOCIETY OF CHEMICAL INDUSTRY.

FOUNDED 1881. INCORPORATED BY ROYAL CHARTER 1907.

CENTRAL HOUSE, 46 & 47, FINSBURY SQUARE, LONDON, E.C. 2.

We, the undersigned Members of the Society of Chemical Industry, hereby propose

(Candidate's Name in full)..

as a fit and proper person to become a Member of the Society of Chemical Industry.

For Names *only* of Members recommending the Candidate. ....

....

....

And I, the said Candidate for Membership, hereby undertake that, if elected, I will be bound by the Charter and By-laws and by any Regulations made thereunder, and will further the objects of the Society.

(Signature of Candidate)..

Address to which the Candidate wishes the Society's Publications to be sent, and which is to be entered in the Society's Register. ....

....

....

Profession or Business Occupation. .... Date..

EXTRACT FROM THE BY-LAWS RELATING TO MEMBERS.

BY-LAW 5.—Every person desirous of being admitted as a Member of the Society shall be duly proposed as a Candidate for admission upon Form (A) set out in the Schedule, or such other form as the Council may from time to time prescribe. The proposal form shall be signed by two Members, to one of whom at the least the Candidate shall be known personally, and every Candidate shall make and subscribe the declaration therein contained—that, if elected, he agrees to be bound by the Charter and By-laws and by any Regulations made thereunder, and to further the objects of the Society. *Proposal of Candidate.*

BY-LAW 6.—All proposal forms of Candidates, duly signed and subscribed as hereinbefore provided, received by the General Secretary prior to an Ordinary Meeting of Council, shall be considered thereat, and the Council may, in their absolute discretion, by resolution passed by a majority of those present, elect or postpone the election of any Candidate as a Member of the Society, or may refuse to elect any Candidate whom they consider to be not a fit or proper person to be elected as aforesaid, and upon such election may also decide whether any Member so elected shall be required to pay for the year then current the whole or any part of the annual or other subscription or other fee hereafter provided, and thereupon the General Secretary shall give notice of such election and decision to the Member elected as aforesaid, and upon such notice and the payment of the said subscription or other fee, the person so elected shall, pursuant to the Charter and By-laws, become and continue to be subject to all the duties and obligations and entitled to all the rights and privileges of a Member. *Election of Members.*

BY-LAW 8.—Except as otherwise decided by the Council, every Member shall, upon notice of his election, in addition to a subscription for the current year in which he is elected, or any payment in lieu thereof, pay to the Treasurer, or other person appointed by the Council to receive Members' fees or subscriptions, an entrance fee of One Guinea, or such other amount as may for the time being be prescribed by Regulations. *Entrance Fee.*

BY-LAW 9.—Every Member shall on the First day of January in each year pay to the Treasurer, or other person as aforesaid, the sum of Two Pounds Ten Shillings, or such other sum as the Council may prescribe by Regulations, and every Member shall upon his election pay the like amount, as his subscription for the year current in which he is elected, or such part thereof as may be decided by the Council, but in lieu of any such payment a Member may compound for that and all future payments, as hereinafter provided. *Annual Subscription.*

A Member joining under the age of 25 shall be entitled to pay a subscription of £2 per annum until attaining the age of 25, or for 3 years from date of election, whichever is the longer period, but subject to the provisions that his application for Membership must be accompanied by (1) satisfactory evidence of age, and (2) a declaration that he is not joining the Society as a nominee of any firm or corporation, but solely in his own interests as an individual member.

BY-LAW 11.—Any Member whose annual subscription, payable on the First day of January, is unpaid on the First day of March next following shall, while remaining subject to the duties and obligations, not be entitled to any of the rights of a Member until such subscription shall be paid, and at any time after the First day of March, the General Secretary shall give notice to all Members whose subscriptions are so in arrear, and if any Member on the next ensuing Thirty-first day of December shall continue in arrear, such Member shall cease to be a Member, and his name shall then be removed from the Register by the General Secretary, but without prejudice to the right of the Council to recover any such arrears or to enforce any duty or obligation to which, as a Member, he may have become liable at the time of such removal, in any Court of competent jurisdiction. Notwithstanding anything in this By-law provided, the Council in the exercise of their sole discretion may, having regard to the circumstances in which the subscription of any Member shall be in arrear as aforesaid, postpone or remit the payment thereof, and continue such Member in full enjoyment of all rights of Membership as if such subscription had not at any time been or continued in arrear. *Subscriptions in arrear.*

BY-LAW 13.—Any Member may at any time determine his Membership by notice in writing to that effect, sent to the General Secretary, but such notice in order to operate as a determination shall be accompanied by payment of any subscription or fee which at the date of the notice shall have become payable by the Member, and which remains unpaid. *Resignation of Members.*

N.B.—Entrance Fee suspended for the year 1925.

This form should be completed and signed by the Applicant for membership, and should then be sent to—

THE GENERAL SECRETARY,
SOCIETY OF CHEMICAL INDUSTRY,
CENTRAL HOUSE,
FINSBURY SQUARE,
LONDON, E.C. 2

from whom all further particulars may be obtained on application.

JOURNAL of THE SOCIETY OF CHEMICAL INDUSTRY.

CHEMISTRY & INDUSTRY

Official Organ of the Federal Council of Pure and Applied Chemistry

which consists of Representatives from

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals and the Royal Agricultural Society.

VOL. 43 NEW SERIES — LONDON, OCTOBER 24, 1924 — No. 43

EDITORIAL

WE published last week a list of chemical meetings to be held in London. This list and the list of chemical societies, which appears each week at the top of our first page, should drive home to us the great number of chemical societies which exist and the great expense involved in belonging to the most important of them. It is not only the annual subscription which has to be faced; there are entrance fees on joining the majority of these societies, and the cost of binding the journals at the end of the year is of the same order of magnitude as the annual subscriptions, instead of being, as formerly, a trifling number of shillings. The expense of storing the bound journals is also a housing problem of the utmost importance. The Society of Chemical Industry has recently decided to suspend its entrance fee for the year 1925, and this step will be welcomed by many chemists who feel that such a procedure is a step in the right direction. It remains to be seen whether the additional number of new members who will avail themselves of this opportunity will compensate for the loss of the entrance fees and justify the Society in continuing the policy. There is a constant struggle going on in all the societies between the necessity of making both ends meet and the desire to provide the most for each member at the lowest cost. The struggle affects this journal as it does many others; "publish more articles, more reviews, more items of news," say the majority of our readers; "save fifty pounds a week on printing if you can," say our financial autocrats. This awkward dilemma confronts us every week and every week we have complied with both demands. We have printed more pages of *Chemistry and Industry* this year than during the corresponding period of last year; the pages are about ten per cent. larger than they were; nevertheless the total cost of the *Journal* appears so far to be about four-fifths of the cost during the corresponding period of last year. This considerable economy justified the Council in making the concession to new members we have referred to. It remains for the present members to induce so many of the younger chemists to join the Society that the financial result to the Society will not be more than its resources can endure.

*   *   *

In the Journal of the Franklin Institute for October, 1924, is an interesting paper by Dr. C. B. Lipman and Mr. J. K. Taylor, both of the University of California, entitled: "Do Green Plants have the power of fixing elementary Nitrogen from the Atmosphere?" In the year 1853 a Frenchman, M. Ville, asserted that green plants fixed atmospheric nitrogen. M. Boussingault and Messrs. Lawes, Gilbert and Pugh satisfied themselves and the world at large that green plants had no such power, and for sixty or seventy years their decision has been accepted. More recently two Italians, Messrs. Mameli and Pollacci, made experiments which confirmed M. Ville's original statement. Now Dr. Lipmann and his colleague publish the details of a large number of experiments which also confirm the conclusion of M. Ville. Those who have not performed experiments on plant culture and the determination of nitrogen in plants cannot be expected to follow with adequate care and logic the details of such work and the critical examination of it and of conflicting experiments. Nitrogen may be absorbed by the plant or by bacteria attached to it; the seeds, the solutions in which they germinated, and the air are all possible sources of nitrogen; the nitrogen in the air may be elementary or may exist as ammonia or oxides of nitrogen. All these considerations appear to have been carefully studied by the authors of the paper; the experiments they made were numerous and are described in detail, and the authors themselves are convinced that some plants, for instance wheat and barley, gain nitrogen at the expense of the elementary nitrogen of the atmosphere. Peas seemed to be unable to do this; *Bromus* had a slight power of fixing nitrogen. The authors of the paper have clearly made out a *prima facie* case for such fixation; those who are able to estimate at its true value the evidence they have published will be able, or perhaps unable, to point out errors, fallacies and false deductions. The decision of this vexed

question may be both interesting and important, and we are confident that our readers would welcome a critical examination of the paper we have referred to.

* * *

Prof. Lowry presents us this week not with a dissertation on co-ordination, but with some pithy observations on the psychology of chemists. Just as the expert may detect that in a supersaturated solution there are portions which will soon crystallise, so, too, the observant will notice in Prof. Lowry's historical memoir a number of observations, which he was on the point of making, but has yet retained in a fluid state, nevertheless with a definite orientation or polarisation. The quick reception of new points of view declines with maturity. Mr. Asquith is a little dubious about such a simple scheme as the nationalisation of banks. If a man accepts eagerly a bulky and a boggy bun, he is probably still young in mind and appetite. For chemists a more subtle test is required; there is no one universal elixir which will discriminate between those who are ascending the curve and those whose tangents are already beginning to point downwards. Tests, indeed, there are; they shock the more sedate; photosynthesis, synthetic syrups (sirops as we fancy they are called in dry countries), hydrogen ion concentration, solvation, the re-entrant orbits of the nineteenth electron of strontium, these are examples of the newer phases, corresponding to the shingled hair and the syncopated tunes. But whether the new theories please or displease particular individuals is of very little consequence. The science advances; the substitution theory of Dumas, said to have originated with a smoky candle, has proved serviceable; the tetrahedral conception of the carbon atom has explained many phenomena; ions, electrons and orbits, electrovalency and all other valencies, will all take their places in the great procession proudly marching towards the truth. And, the proud man, dressed with a little brief authority, can do so little to retard progress. He may do much to open up a new avenue, as van't Hoff did. But whether he is easy or worried by new facts or new beliefs is of no moment. *Quand Sa Hautesse envoie un vaisseau en Egypte, s'embarrasse-t-elle si les souris qui sont dans le vaisseau sont à leur aise ou non ?*

The development of chemistry as a science and as an essential ingredient of modern industry and civilisation is as certain as the revolution of the planets in the solar system. Its teaching can neither be ignored nor forgotten :—

> The Moving Finger writes; and having writ
> Moves on; nor all your Piety nor Wit
> Shall lure it back to cancel half a line,
> Nor all your Tears wash out a Word of it.

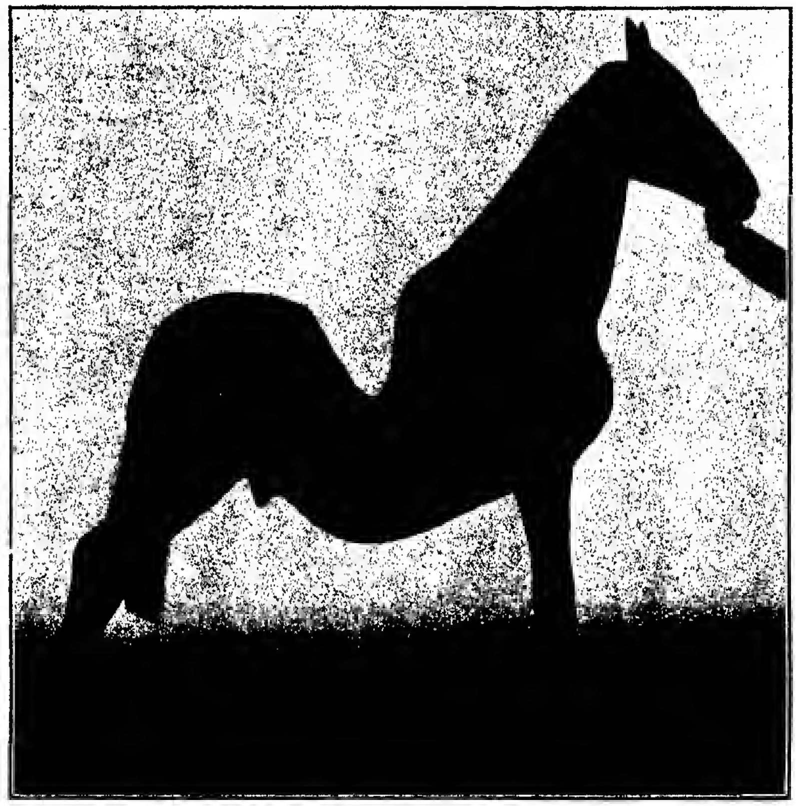
We are proud of the part which the Society of Chemical Industry takes in making known the new facts, and the new theories. When we glance over any of the past volumes we realise how immense is the service the Society has rendered, how essential it is that this be maintained and how glad are those who spend so much of their time in organising the Society, its Sections and its Engineering Group.

MEN AND MANNERS
I—THE PEGASUS OF VAN'T HOFF

1. If a student of organic chemistry were asked to name the two features which form the crowning glory of that branch of science, it is almost certain that his reply would include at least one of the following :—First, the development of structural formulæ, based upon the quadrivalency of carbon, whereby the whole of the reactions of a compound can be summarised in a single picture. Second, the tetrahedral model of the carbon atom, with the explanations that it gives of ring-formation, stereoisomerism, and the still more delicate phenomena of optical isomerism. It is therefore both interesting and instructive to recall the way in which these supremely important discoveries were received by a chemist of the old school, nourished on the "sincere milk of the word," the unadulterated "Gospel according to Berzelius." The story has to some extent fallen into oblivion, but is set forth in outline in Schorlemmer's "Rise and Development of Organic Chemistry," perhaps the most fascinating book on organic chemistry that has yet been written. Schorlemmer's picture of Kolbe attacking Kekulé, Wislicenus, van't Hoff, Fischer, and von Baeyer in turn is, however, sufficiently amusing to justify a search through Kolbe's papers for the original references, which Schorlemmer does not give.

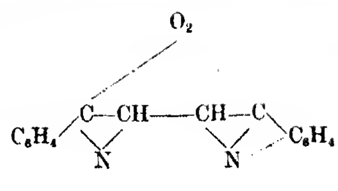
2. The attack upon Kekulé is contained in a "Criticism of Aug. Kekulé's address 'On the Scientific Aims and Achievements of Chemistry,'" (*J. für prakt. Chem.*, 1878, **125**, 139-156) on the occasion of his inauguration as Rector of the University of Bonn in October, 1877. Kolbe asserts that "During the last 15 years nobody in Germany has exerted a worse influence upon exact chemical research and on the young chemist than Kekulé. The beautiful experimental work which he published in 1858 on mercury fulminate and on glycollic acid, and in 1861—1864 on succinic, fumaric, pyruvic, and itaconic acids, justified the expectation that this still youthful chemist would enrich our science with yet more important discoveries. These expectations have been disappointed. . . . Instead of valuable chemical discoveries he has given to chemistry only two phantasies, the so-called theory of bonds and the doctrine of the benzene-ring. This was the beginning of the great decline of chemistry in Germany. . . . And not only do young inexperienced chemists follow eagerly the direction pointed out by Kekulé . . . but older chemists also have allowed themselves to be seduced into treading the same path. Our science is not permanently injured by such ephemeral abberations; more to be pitied are the young chemists educated in such schools, who learn to arrange the atoms in chains, to write elegant structural formulæ, and by working to a pattern to increase somewhat the number of ortho-, para- and meta-compounds, but have little experience, especially in the field of inorganic chemistry. Is it to be wondered at that our chemical manufacturers have now a great prejudice against the theorising but useless chemists turned out by the universities and technical schools ?"

These criticisms fill sixteen pages of text with polemical matter, the publication of which is accounted for by the fact that Kolbe was himself the editor of the journal in which they appeared. They conclude with a suggestion that Kekulé's speculations might be completed by assuming that molecules, which are fixed by bonds in three dimensions, may still possess freedom of vibration in a fourth dimension! This view has, I believe, been revived in recent years as the basis of a mechanism for the Walden inversion, but the theory is Kolbe's own. Kolbe's deliberate jest is, however, perhaps less humorous than his repetition of the perennial wail about the seducing of youth, since this alleged seduction had been used more than 2000 years ago as an excuse for an experimental research by Socrates on the narcotic properties of coniine.

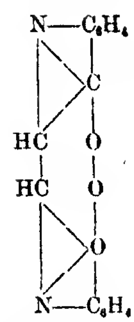


The "Pegasus of van't Hoff"

3. Kolbe's lament, that the spread of structural chemistry had brought about a revolt of chemical manufacturers against the university-trained chemist, receives added interest from the fact that he made a special attack upon von Baeyer in connexion with his investigations on the structural formula of indigo. The discovery of the structure of this compound, and the syntheses which followed almost inevitably from it, provided materials for the supreme triumph of German organic chemistry in the industrial field; but this would scarcely have been possible if the manufacturers had not adopted a more enlightened view than their academic colleague of the value of theoretical chemistry. In this particular case, Kolbe's humour consisted in writing the formula in two ways, the first being "indigo in the form of an umbrella, with cover and knob, but minus a stick" whilst the second shows indigo "in the form of a tower with a winding staircase" (*J. für prakt. Chem.*, 1883, **25**, 257).



The indigo umbrella



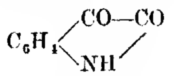
The indigo turret

Kolbe's own views on the structure of this group of compounds are set out in a paper under the title,

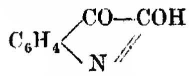
"What is isatin?" (*J. für prakt. Chem.*, 1883, **27**, 491); but they are scarcely intelligible to a modern reader. Thus, he asserts that—

"Isatin=$(C_6\left\{\begin{matrix}H_4\\N\end{matrix}\right\}CO)COH$ (Stickstoff benzoyl-Formyl)"

On the other hand, Baeyer's two formulæ for isatin are supplied with descriptive titles as follows (*J. für prakt. Chem.*, 1883, **28**, 39).



Old hieroglyphics



New hieroglyphics

A separate article (*J. für prakt. Chem.*, 1882, **26**, 308) under the provocative title, "Reasons for my Judgment on Ad. Baeyer's Scientific Qualifications," is devoted to a criticism of von Baeyer's work on the phthaleins, whilst the fertile conception of the "mobility of hydrogen atoms" is adversely criticised in another article (*J. für prakt. Chem.*, 1884, **29**, p. 32) under the title, "The Present Distressful State of Chemistry."

4. The main attack on van't Hoff is contained in the second of two articles under the title, "Signs of the Times" (*J. für prakt. Chem.*, 1876, **122**, 268; 1877, **123**, 473). In the first of these articles, Kolbe had made a strenuous attack on the unnamed author of a paper on "Aromatic Compounds of Phosphorus," who had maintained very reasonably that the structural formulæ of organic chemistry formed an almost complete system, whilst the corresponding aspects of inorganic chemistry were still in a very rudimentary condition. In the second article he laments that speculative science, which had been displaced fifty years before by exact research, was now being "brought out again by sham research workers from the lumber-room in which the errors of the human mind are stored," and was trying "to smuggle itself into a society to which it did not belong, like a hussy with new clothes and freshly-powdered." As an illustration of this remarkable phenomenon he quotes the recently published paper of van't Hoff on "The Arrangement of Atoms in Space"! He suggests that any who regard his anxiety as to the progress of chemical research as exaggerated should read "if they can" this mixture of fantasy and folly. He was, however, particularly angry because van't Hoff held an appointment at the Veterinary College at Utrecht, whilst the translator of the pamphlet was an assistant at an Agricultural Institute in Heidelberg. Kolbe apparently still questioned whether any good thing could "come out of Nazareth" as represented by these two schools of applied science. He regards it as "a sign of our present poverty of and hatred of criticism" that two almost unknown chemists, occupying positions such as these, should dare to attempt a solution of the highest problems in chemistry. But he would not have deigned to take any notice of their work if Wislicenus, against whom no such devastating accusation could be made, had not "in an incomprehensible way" written an introduction to it. Moreover, instead of treating it as a joke, he had seriously recommended it as a meritorious work. By doing this, however, Wislicenus had openly withdrawn from the ranks of exact research workers, and gone over to a camp of speculative philosophers who could scarcely be distinguished from spiritualists! The same accusation was levelled against Kekulé, who, instead of "jeering at the nonsense" of van't Hoff's hypothesis of the asymmetric carbon atom, had actually included it, in his rectorial address, amongst the achievements of chemistry.

5. The passage which has gained for Kolbe the largest measure of notoriety is, however, the one in which he says that "A certain Dr. J. H. van't Hoff, who holds an appointment at the Veterinary College of Utrecht, has, it appears, no taste for exact chemical research. He has thought it easier to bestride Pegasus (probably borrowed from the Veterinary College) and to proclaim in his *La Chimie dans l'Espace* how on his bold flight to the Chemical Parnassus the atoms appeared to be arranged in space." This fantastic picture, with its irrelevant reference to van't Hoff's appointment, obviously called for some embellishment in order to do justice to the situation. By a fortunate accident, there came into the veterinary stables a horse which was wholly worthy to play the part of Pegasus. This noble animal was therefore promptly led out to be photographed, and to this day the photograph adorns the walls of the Veterinary College at Utrecht. Through the kindness of Dr. Byl, and by the courteous permission of Prof. Krediet, a copy of this photograph is reproduced as an illustration to this article, and as a souvenir of a critic who, with uncanny accuracy, succeeded every time in "putting his money on the wrong horse" and persistently failed to recognise a winner. So certain, indeed, was Kolbe's judgment that he could scarcely have paid any higher compliment to one of his contemporaries than to include his name in his "black list," with all the greatest chemists of his day from Kekulé to Fischer.

T. M. Lowry

MINING AND METALLURGY IN CANADA

An examination of the natural gas from the well at Inglewood, Peel County, Ontario, shows that it contains one per cent. helium.

The value of the mineral production of British Columbia for 1923 was \$41,304,320, as compared with \$33,153,843 in 1922. The metallic production was as follows: Gold (placer), \$420,000; gold (lode), \$3,704,994; silver, \$3,718,129; copper, \$8,323,266; lead, \$6,321,770; zinc, \$3,278,903. There was a general decline in mineral production in the northern districts, but a substantial increase in southern B.C. The gross production of coal was 2,542,987 tons, a slight decrease compared with 1922. The Fordney tariff in U.S.A. and competition of Californian oil accounts for the falling-off in demand.

The Pacific Coast mines in South Wellington district, at one time the chief producers of coal, which have been closed down for some time, will be re-opened under the control of a new group of Eastern capitalists.

INSTITUTE OF BREWING RESEARCH SCHEME

An Epistle to the Research Committee of the Institute of Brewing, the Lawes Trust Committee, the Wye College Research Committee and Agricultural Experiment Stations generally.

It is well known that a study of barley and of hops is being made on behalf of the Institute of Brewing. As an honorary brewer and a confirmed believer in beer, I naturally take an interest in the proceedings of the Institute and, therefore, have been greatly perturbed by adverse criticisms which have reached my ears of the work on barley, in particular. Those who wish to read up the subject may consult a paper on "The Barley Crop: a Study in Modern Agricultural Chemistry," by Dr. E. J. Russell, in the Journal of the Institute, Vol. XIX, new series, 1922, pp. 697—717; also two Reports by the Director of the Rothamsted Experiment Station on "Experiments carried out in 1922 and 1923" (*ibid*, Vol. XX, 624—654, Vol. XXI, 618—837). The experiments are in charge of a special sub-committee, of which the Director of Rothamsted is Chairman. Field trials have been specially made not only at Rothamsted but also at about a dozen other centres, the object, we are told, being to determine :—

1. The influence of environmental conditions (soil, season and manuring) on the yield and quality of barley;
2. The relationship of chemical composition of barley to malting and brewing value.

The same seed and the same manure is used at all the stations, so that soil and climate are the two variables affecting the results.

I will not discuss the need and value of such experiments on the yield of barley, but turn at once to the question of quality, as being of primary importance. Putting aside the fact that quality for brewing is one thing and quality for feeding another, we have first to inquire: "How is quality (for brewing) defined and determined?" The answer is blankly: "Quality is neither defined nor is it definable at present; it is a matter of mere personal judgment, depending upon experience in both maltster and brewer. Both regard what is obviously a C_1 product —a mature, well-conditioned grain—as that of highest quality. It is true, a high percentage of nitrogen is usually to be associated with immature development of the grain; given a fair maturity of growth, however, *the test of practice*, mainly that of appearance, seems to be the only recognised and public* criterion of quality.

This is the point I wish to make—in Brewing-Land "there ain't a single commandment; if a man raise a thirst, he must somehow satisfy it with a product of empiricism and art, not of science."

* I use this expression advisedly, because brewers are not all prepared to state the nature of their requirements—what constitutes quality, in their opinion. Messrs. Guinness and Co., we know, decline to make the results of their inquiries in any way public and at least one other large brewing firm assumes this attitude. Neither the farmer nor the academic student can work blindfold: the brewing industry must play the game in its entirety, if the problems of its industry are to be solved with the aid of outside scientific studies, as inquiries cannot be conducted fruitfully without a knowledge of every detail and reciprocal exchange of information.

This, I take it, is the criticism abroad of the Institute's action: it is to be feared it is valid.

The same is true of hops.

Argle: field trials, whether with barley or with hops, such as have been instituted, are of little, if any, value, so long as we are without definite criteria of quality.

Agriculturists have not the slightest need to make experiments to determine the yield without as well as with nitrogenous manure. It is long since established that an economic yield of a cereal is only possible when a sufficiency of nitrogen is presented to the plant.

We know also that the plant, like the human being, requires a complete diet—everything in due proportion, although the seed, like the infant, will drain its parent and will even flourish upon a feeble stock: so it is necessary to take into account the growth of the plant as a whole, not merely the grain. Wherever grain be grown, the condition of the soil, not merely the manurial treatment of the moment, has to be considered. Barley is generally grown in this country following a heavily manured root crop, which may or may not be folded off; if not, as a second straw crop, following wheat, after clover or a succession of green crops. In the first case there is no question of an application of nitrogen: the danger is that the land already contains an excess. In the second case, the need or otherwise of nitrogen will be determined by the strength of the land and whether it have been well manured or not for previous crops. It is inevitable that nitrogen will give a positive result in some trials, a negative in others. What general conclusion then can be drawn? The same is true of phosphates and potash: they may be wanted or not, according to the character of the soil and the previous treatment of the land. It is difficult, therefore, to see what material for the study either of yield or of quality can accrue from the observation of plots treated as described that is not already available from the Rothamsted experiments and Messrs. Beaven and Munro's study of the barleys. An altogether different type of experiment must be developed, if the problem before the grower of high-grade barley is to be elucidated—that of combining high yield with high quality.

Agriculturists have carried on tentative and crude field trials of this order long enough: the time is come to take stock of the situation and seek to develop an improved technique, one which can be termed "scientific." There is a worthy past to be considered, which merits the closest study, as affording lessons for the future; in fact, we need to retire for a time and live on the balance we have accumulated, until we have devised sure means of developing anew our attack on Nature

Turning to the brewing process, this is one of extraordinary intricacy, the grain being a plexus of variables—carbohydrates, proteins, salts, etc. It is almost a vital process; is so, indeed, in its final fermentative stage. We know that enzymes are developed during malting which are operative during mashing; these undoubtedly vary in quantity and the quality of their effect depends greatly upon the conditions to which they are subject.

Our policy is clear. The brewer must possess his soul with patience until we have ascertained something of the composition of his raw materials—and of the agents (self-contained) to which they are subject during malting and brewing; when components and agents are sorted out, their individual interactions must be studied. This is the classic method inaugurated by Emil Fischer, which has given his work its preponderating value. Starting with the foundation stone, taking care to measure and define each brick that he laid, he built up a structure of which every part was known. There is no other method.

Thirty years ago, I began to study the Rothamsted cereals. We measured everything we could: weight, density and volume of the grain, weight per thousand seeds, percentage of water, percentage of nitrogen and of ashes; then we attempted to "analyse" the grain and determine the percentage of "Starch"; but using wheat broke down hopelessly and put the work aside, hoping for better times. Before 1880, I had my suspicions of "Starch" and felt sure that several enzymes were concerned in the mashing process; the difficulty was to dissect them out; we then knew but little of such agents. The subject was constantly under discussion among us but the horizon was long obscured by clouds—my school, I am proud to say, has done not a little to lift these and now we are beginning to see daylight. Our work on enzymes has helped to make the foundations secure and hopeful methods of attack on "*Diastase*" are foreshadowed. As to "Starch," the scales are almost suddenly fallen from our eyes and we begin to see it in its true proportions, largely through the illuminating work of Prof. Ling, the head of the Midland Brewing School, perhaps the pupil of whom I am most proud. Starch, it seems, may have at least three components—*Amylose* or, as I should prefer to call it, *Amylum* (reserving the *ose* termination for reducing compounds); *Amylopectin* (or its phosphate); *Hemicellulose*. Each of these, probably, is resolved in the mash by a different enzyme. Several years ago, when my former assistant, Mr. Horton, was unable to verify the remarkable *Taka-diastase* method of determining starch elaborated by Mr. W. A. Davis, another of my pupils, it was clear that there had been some alteration with time in the character of the "Diastase"; discussing the matter together, we came to the conclusion that it was necessary to tackle the problem systematically, more or less on lines which had been successfully followed in the study of amygdalin; that the various carbohydrates in starch or producible from it should be dealt with individually and the enzymes dissected out with their aid; we had even contemplated beginning with Julian Baker's amylodextrin. The proteins must be similarly studied.

When we have accurate methods at our disposal, we shall have sufficient material in the accumulated Rothamsted samples to determine the nature of the variations due to manurial treatment and season. Then only will it be possible to go further afield and advise both farmer and brewer and consider climatic effects. It may be a long lane and one difficult to walk; still, it will have a clear and sure turning.

The same argument holds for hops. Experiments on drying probably are of value, as they serve a practical end. So much is known of the manurial treatment of the crop, however, that little can be learnt of practical value by further experiments. The trials are mainly of worth as demonstrations to growers of the special value of phosphates. As to breeding new varieties, not much can be done without clearer guiding criteria. Flavour is a matter of personal opinion. As to preservative power, Mr. Lloyd Hind's Report (*Journal of the Institute of Brewing*, Vol. XXI, p. 725) is disconcerting: "The results show," he says, "that whatever substances constituted the preservative of hops, they were not the soft resins in their entirety, neither did they form a definite proportion of the soft resins. They seem to be associated with it and roughly it might be said that high resins go with high preservative power." Clearly, as in the case of barley, further study in the brewery and the laboratory should precede exhaustive field trials. Even resistance to disease may be more a question of conditions of cultivation and growth than of any specific quality in the hop plant.

I would ask the three Committees, therefore, to take complete stock of the situation before embarking on further extensive field inquiries. I would urge the Institute, for a time, to give the Birmingham stable all the backing it needs and to be very liberal. Prof. Ling has let loose the bloodhounds of inquiry in a way that should make the pursuit of the quarry a certainty of the not too distant future. It is a strange reflexion upon the narrowness of scientific outlook, that in a city of brass—though not of "paint an' putty"—so much should have been done to probe a problem of utmost importance to the husbandry of the world and that the centres of agricultural inquiry should have shown little or no vital interest in the plant's activity. That touch of Nature which should make the laboratory kin with the fair fields has thus far been wanting: apparently, chemico-physical and biological instincts are rarely conjoined. We may well leave the soil for a time and steadily work at the plant, at which we have so long gazed but merely weighed-up. We talk big of Agricultural Chemistry but no real chemistry, no organic or natural chemistry, has thus far been put into it. We chemists, in fact, are not sufficiently mindful of our opportunities and of the call there is upon us for work of practical value. It were well for us to bear in mind the warning:—

> There is a world outside the one you know,
>   To which for curiousness 'ell can't compare.
> It is the place where wilful-missings go,
>   As we can testify for we are there.

It is nothing short of intolerable that we should have left the field of inquiry into the quality of foodstuffs generally almost untilled. The need of maintaining dyestuff works which can be used in the event of war to produce poisons is often enough instilled into us; the need of *complete* study of the nature and value of foodstuffs, never! We need now to focus our efforts upon the determination of the significant constituents. The effect of manurial treatment can then be inferred from the vast mass of material awaiting effective analysis at Rothamsted.

HENRY E. ARMSTRONG

FORTHCOMING EVENTS

Oct. 25. BIOCHEMICAL SOCIETY, School of Biochemistry, Tennis Court Road, Cambridge, at 3.30 p.m. (1) "Fractional Ultra-filtration of Serum Proteins," by A. B. Anderson. (2) "The Carbohydrates and Fat Metabolism of Yeast," by D. Hoffert and I. S. MacLean. (3) "The Isolation of Spermine and its Chemical Composition," by H. W. Dudley, and M. C. and O. Rosenheim. (4) "The Influence of Spa Waters upon Urinary Excretion," by P. C. Raiment and G. L. Peskett. (5) "On the Micro Estimation of Urea in 0·2 c.c. of Blood," by G. Thomas. (6) "The Acid-Soluble Phosphorus Compounds in Milk," by H. D. Kay. (7) "The Effect of Acidose on Calcium and Potassium in Plasma and Urine," by J. B. S. Haldane, J. Hicks, and C. Watchorn.

Oct. 25. MINING INSTITUTE OF SCOTLAND, Royal Technical College, George Street, Glasgow, at 3 p.m. "Industrial Standardisation," by Mr. C. LeMaistre.

Oct. 25. HULL ASSOCIATION OF ENGINEERS, Municipal Technical College, Park Street, Hull. "Modern Constructional Plant and its Application," by I. W. BENSON.

Oct. 28. INSTITUTION OF CIVIL ENGINEERS, Great George Street, London, S.W. 1, at 6 p.m. "The Economic Position of Great Britain," by E. Crammond.

Oct. 29. SOCIETY OF CHEMICAL INDUSTRY, *Newcastle-on-Tyne Section*, Armstrong College, Newcastle-on-Tyne, at 7.30 p.m. "The Oppau Explosion," by Prof. W. N. Haworth.

Oct. 29 and 30. SOCIETY OF CHEMICAL INDUSTRY, Nottingham Section, University College, Nottingham, at 5 p.m. Dr. W. Lawrence Balls will open a Discussion on "Textiles" with the Faraday Society.

Oct. 20. FARADAY SOCIETY, at the Institution of Electrical Engineers, Victoria Embankment, Savoy Place, W.C., at 5.30 p.m. "Electrical Precipitation," by Sir Oliver Lodge, F.R.S.

Oct. 30. UNIVERSITY OF SHEFFIELD, DEPARTMENT OF FUEL TECHNOLOGY. A course of six lectures on "Furnace Heating" will be given by R. J. Sarjant M.Sc., at St. George's Square, Sheffield, at 5.15 p.m. on successive Thursday afternoons.

Oct. 30. TEXTILE INSTITUTE, *London Section*, 38, Bloomsbury Square, London, W.C. 1, at 7 p.m. "Artificial Silk Fabrics," by R. Boettcher.

Oct. 30. SOCIETY OF DYERS AND COLOURISTS, *Midlands Section*, University College, Nottingham. "The Dyeing of Leather," by M. C. Lamb.

Oct. 30. INSTITUTION OF MECHANICAL ENGINEERS, *Birmingham Section*, Queen's Hotel, Birmingham, at 6.30 p.m. "Co-partnership in Industry," by Major S. J. Thompson.

Oct. 30. INSTITUTION OF MECHANICAL ENGINEERS, *North Western Branch*, Annual Dinner, at the Engineers' Club, Manchester, at 7 p.m.

Oct. 31. INSTITUTION OF MECHANICAL ENGINEERS, STOREY'S GATE, LONDON, S.W. 1 Informal meeting at 7 p.m. Discussion on "Engineering Novelties at the British Empire Exhibition."

Oct. 31. INSTITUTION OF MECHANICAL ENGINEERS, The University, Leeds, at 7.30 p.m. "Heat-Loss in Gas Engines," by Prof. W. T. David, M.A.

Nov. 3. SOCIETY OF CHEMICAL INDUSTRY, *London Section*, at 8 p.m. "Experiments in Protection," by W. J. U. Woolcock, C.B.E. Members may dine at the Club before the Meeting.

SOCIETY OF CHEMICAL INDUSTRY

CHEMICAL INDUSTRY DINNER

The Autumn Dinner, which will be under the auspices of the Society of Chemical Industry and the Chemical Industry Club, will be held in the Edward VII Rooms of the Hotel Victoria, Northumberland Avenue, London, W.C. 2, on Friday, November 14, at 7 for 7.30 p.m., and will be presided over by Mr. W. J. U. Woolcock, C.B.E., President of the Society.

A circular letter with further particulars and a form of application for tickets has been sent out to the members.

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

The price of Volume VIII (1923) to members of the Society is 7s. 6d., and to non-members 12s. 6d., post free in each case.

Fellows of the Chemical Society have the privilege of purchasing the volume at the price of 10s. post free.

A set of Volumes II to VIII inclusive can be purchased by a member of the Society at the price of £2 2s. 6d., and by a non-member at the price of £3 15s., post free in each case.

MEMBERS ELECTED, October 10, 1924

Carsley, Samuel H., 31, Macgregor Street, Montreal, P.Q., Canada. Instructor in Chemistry. (Queen's University).

Cash, Louis S., 36, Sinclair Street, Wollstonecraft, Sydney, New South Wales, Australia. Works Chemist.

Gibson, Alfred L., Department of Chemistry, Ontario Agricultural College, Guelph, Ont., Canada. Professor.

Hopkins, Stanley, Messrs. Ruths Steam Accumulator Co., Ltd., 45, Kingsway, London, W.C. 2. Manager.

Howell, Herbert T., Trichy Road, Coimbatore, South India. Chemist and Works Manager.

Ingledew, Arthur E., c/o Eastern Coal Co., Ltd., Bhowra Colliery, P.O. Box 102, Jamadoba P.O., Manbhum, India. Analytical Chemist.

Ingold, Christopher K., F.R.S., The University, Leeds. Professor of Organic Chemistry.

Mann, Thomas, c/o Messrs. Hellon and Mann, 40, Lowther Street, Whitehaven. Analytical Chemist.

Preen, Frank H. E., c/o Dr. Thuna, 436, Queen Street West, Toronto, Ontario, Canada. Consulting Chemist.

Staton, Rowland, The Brown-Firth Research Laboratories, Princess Street, Sheffield. Metallurgical Assistant.

Topley, John W. M., 84, Coombe Road, New Malden, Surrey. Engineer.

Tucker, Percy A., Birmingham Central Laboratories, 59, Cambridge Street, Birmingham. Metallurgical Chemist.

Wedgwood, Philip, 11, Chalsey Road, Brockley, London, S.E. 4. Gas Chemist.

Wood, Cecil Wm., National Oil Refineries, Ltd., Skewen, Glam., South Wales. Chemist.

BRISTOL SECTION

The opening meeting of the Session was held in the University Chemical Department, Mr. M. W. Jones presiding over an excellent attendance.

As the meeting was held jointly with the Bristol and South-Western Counties section of the Institute of Chemistry, the ceremony of admission for three Associates of the Institute was carried out by Mr. C. J. Waterfall.

Dr. M. Nierenstein then read a paper on the "Present Position of the Catechin Chemistry." Catechin is an astringent principle found in cutch, a substance used in the East for dyeing and tanning, and occasionally in medicine. The lecturer described the preparation of various forms of crystalline catechin, and showed the constitution of those that had been investigated. The research work had been carried out in the biochemical laboratory of the University, with the assistance of Miss Hazleton and Dr. Hooper.

Amongst those who took part in the discussion were Dr. Rixon, Dr. Mann, and Mr. Jones. Dr. Mann, who is Director of Agriculture to the Government of Bombay, provided the material used in the investigations. Speaking of the uses of cutch in India, he described the use of cutch, mixed with pan leaves and betel nut, as a masticatory esteemed by the natives as a stimulant and aid to digestion.

CHEMICAL ENGINEERING GROUP

At the meeting of the Chemical Engineering Group, held on October 23, in the Engineers' Club, two papers were read.

A paper was presented by Mr. T. V. Barker, entitled "The Development and Formation of Crystals," which gave a general account of the results accruing from the purely scientific study of crystals, without touching upon the industrial aspect of the subject. Some of the points dealt with were crystal form and symmetry, the lattice structure of a crystal, polymorphism and isomorphism, crystal mixtures, physical properties of crystals, the chemistry of the crystalline condition and the enigma of crystal form. Many diagrams were given to illustrate the various points raised, which were of particular interest, as the author restricted the discussion to topics not adequately described elsewhere.

In a paper entitled "Mechanical Crystallisation," Mr. Hugh Griffiths said very few of the researches on the dynamics of crystallisation were of interest to the chemical engineer. For this reason, crystallisation was too often regarded as a "craft," not a "science," in industry. In many chemical works the moment a crystallising process came for consideration, the stationary vessel was installed without question, because it was very cheap. It was not, however, cheap to operate, and in addition, frequently the saving in capital cost was more than counterbalanced by the enormous stock of material which had to be carried in process. Mr. Griffiths first discussed the properties of crystallising solutions, and finally dealt with (1) plants for uncontrolled crystallisation, and (2) plants for controlled crystallisation.

THE PRIESTLEY LECTURE AT BIRMINGHAM

Prof. G. T. Morgan, F.R.S., head of the Chemistry Department at the University of Birmingham, delivered the annual Priestley Lecture on October 17, at the Midland Institute, Birmingham. Reviewing Priestley's work as a chemical investigator Prof. Morgan said his earliest study began with "fixed air" or carbon dioxide. In consequence of being near a brewery, Priestley was led to experiment on the fixed air arising from the fermentation vats by studying its effects on burning candles, on living animals, and in water. He noted that water saturated with the fixed air had a pleasant acidulous taste, and he recommended this solution as a substitute for natural aerated water, communicating his discovery to the Royal Society and to the Admiralty. In this way Priestley became the founder of the mineral-water industry. The lecturer then described the discovery of oxygen, or as Priestley called it, "dephlogisticated air." Priestley suggested the new gas might prove beneficial for certain morbid conditions of the lungs, or that, being a powerful supporter of combustion, it might be used in producing high temperatures in certain metallurgical operations such as the melting of platinum. These suggestions had since been put in practice. Prof. Morgan traced the subsequent development of oxygen up to the modern process of liquefaction of air. The quantity now distributed in Great Britain in cylinders is 300 million cb. ft. a year. One per cent. of the output is used for medical purposes, 3 per cent. for limelight, and for experimental work and research; the rest of the gas is used in industry, metal-cutting representing 59 per cent., welding, 25 per cent., and the remainder being used in producing high temperatures for special metallurgical operations.

THE SPIRIT OF SCIENCE

The inaugural meeting of the Chemistry Section of the Leicester Literary and Philosophical Society on October 15 was devoted to an address by Prof. H. E. Armstrong, F.R.S., on "The Spirit of Science," of which an abstract is appended.

Indulgence, even deep indulgence, in a scientific occupation, even the possession of great scientific ability in some particular field, does not necessarily make a man scientifically sane all over. Apparently, our brains are compartmented, and the compartments are not necessarily all interlocked.

We are creatures of evolution, and under the severe conditions of nature only those have survived who could think together, work together and wonder together. Just as a man has selected certain tools suited to his daily use, so we have been selected as types, fitted to the society in which we have lived. To-day, freedom of thought is beginning to be allowed, and every kind of freak is having his chance, the scientific worker among them. Unfortunately, just as freedom is coming on, those most fitted to be free have elected to kill out their type. Freaks are admittedly dangerous, and the scientific freak has proved himself to be capable of anything—he is fast

undermining the foundations of society and has made the whole world kin. His doings and his power must be understood, if we are to reconstitute society upon a stable basis.

The human mind has a trick of tying itself into knots and prefers to follow fashion rather than reason. It is a strange mechanism, and like the mechanisms we ourselves construct, varies greatly both in kind and in perfection. Our position is aptly summed up by the most distinguished French literary man of the day in saying :—

"I know that there is no certainty outside science, but I know also that the worth of scientific truth lies in the methods of its discovery, and that those methods are not to be arrived at by the common run of mankind."

Surely our duty is to learn all we can of the method which underlies modern progress and modern practice; to do what we can to overcome the imperfections of our understanding. I believe it to be no longer merely a question of inviting people generally to become interested in science and take up the study of scientific method. No, it is a matter of immediate urgency: not only our material safety but our peace of mind, and our whole mental outlook are at stake.

The prime mission of science being the search after truth, science and pure religion—religion divested of dogma—cannot be in conflict. The Church of the future should be the first to advocate and use scientific method in the service of morality and ethics of conduct. Science has a great social constructive work before it, to demonstrate and develop the power of human understanding and our ability to trust in ourselves.

The primary need of the day is the abandonment of jargon—that cleric and scientist alike should talk in terms that can be understood of the masses.

The spirit of science is the art of calculated, reverent inquiry into all things—which we call scientific method. At present we do but educate the worser part. Adapting a writer of the day, Education may make us ignorant, but we are born inquisitive. There is no imagination, no real purpose in our system. Surely it is for us to take arms against our sea of troubles by turning our thoughts earthwards and seeking to enjoy and know what is ours, to have and to hold till death do us part, recognising that there is infinite beauty spread out for our enjoyment, satisfied to believe that we are but the present links in an ever-moving chain, and that it is our prime duty to make each link fulfil its due purpose.

ACADÉMIE DES SCIENCES

On October 13, M. Desgrez communicated a paper by MM. Caille and Viel on the transformation of chemical complexes, the particular work referring to the displacement by mercury of antimony from solutions of iodostibinate of pyridine, piperidine, theobromine, nicotine, etc., in hydrochloric acid. Prof. D. Berthelot summarised researches by M. C. Henry on the heat given out by animals at constant temperatures, showing that it is possible to apply the theoretical formulæ established for radiation from black bodies. Prof. Urbain read a paper by MM. Marie and Lejeune on the influence of colloids on surface tension. The question of the presence of colloids in certain mineral waters was raised in a paper by MM. Henrijean and Kopaczewski. The instability of bicarbonated water has already been referred to the presence of colloids, but it can be explained either by chemical reactions or by the presence of molecular complexes. In the case of the ferruginous bicarbonated water of Spa the instability is caused by colloids, for these authors have shown, with the aid of a new method, the presence of iron in colloidal form.

INSTITUTE OF PETROLEUM TECHNOLOGY

At the opening meeting of the session, held at the House of the Royal Society of Arts, October 7, the following awards of Medals and Scholarships were announced :—

The Boverton Redwood Medal.—This Medal, which has been presented to the Institution by Mr. Alexander Duckham to commemorate the late Sir Boverton Redwood, founder and first president of the Institution, is awarded to the author of the paper of the greatest merit on any subject connected with Petroleum Technology, presented to the Institution during two consecutive sessions ; preference being given to original work. The award is not confined to members of the Institution, and can be withheld if the Council consider that no paper of sufficiently outstanding merit has been presented.

It has been decided that the award should be made retrospective to 1919, the date of Sir Boverton Redwood's death, and so for the Sessions 1919–20 and 1920–21, it has been awarded to M. Paul de Chambrier, of Pechelbronn, for his paper on the "Working of Petroleum by means of 'Shafts' and 'Galleries'," which was read before the Institution on February 15, 1921. It is hoped that, if M. Paul de Chambrier can be present, the Medal will be presented to him at the seventh annual dinner of the Institution, which is to be held at the Connaught Rooms, Great Queen Street, London, on March 17 next.

As there was no paper of outstanding merit for the Sessions 1921–22 and 1922–23, no award has been made for those sessions.

Students' Medal and Prize.—This Medal and Prize, given by the Institution, is awarded to the student member of the Institution who presents the best paper on any subject connected with petroleum technology, in any one session. The Medal and Prize has been awarded to Lieut. J. H. Blakiston, R.N.R. (late student of the oil-technology course at Birmingham University), for his paper, entitled "The Oilfields of Roumania." This is the first award of this Medal and Prize.

The Institution's Scholarships.—These scholarships are awarded annually, one each to the Royal School of Mines, Imperial College of Science and Technology, London, and to Birmingham University, to a third-year student, taking the petroleum technology course who is also a student member of the Institution. The award is made on the recommendation of his

professors, and is to assist him with his fourth-year studies. The award to the student at the Royal School of Mines has been made to Mr. Ernest Clark, and the award to Birmingham University will be announced shortly.

CHEMICAL SOCIETY

At the first ordinary scientific meeting of the new session, held on Thursday, October 16, a resolution commemorating the late Sir James Dobbie was put from the Chair by the President, Prof. W. P. Wynne, and was adopted in silence by a standing vote. Reference was made to the Address which had recently been presented to the Franklin Institute and the congratulations conveyed to the Rensselaer Polytechnic Institute, Troy, on the occasion of their centenary celebrations, to the Address which would shortly be presented to the Netherlands Chemical Society and the Netherlands Society of Chemical Industry, and to the congratulatory message which had been sent to the new Indian Chemical Society. The President then announced that Dr. N. V. Sidgwick had been appointed Chairman of the Publication Committee; that the Society's representatives on the Bureau of Chemical Abstracts had been reappointed for the ensuing year; that the arrangements with the Society of Chemical Industry and the American Chemical Society regarding the price to Fellows of their publications had been renewed; and that the entrance fee of £3 had, for the present, been suspended. A meeting of the Research Fund Committee would be held in December; applications for grants and reports connected with outstanding grants must be received by December 1. Applications from Fellows would receive priority of consideration.

The following communication was then made by Dr. R. Lessing:—

The influence of catalysts on carbonisation [with M. A. Lister Banks].

THE catalytic effect of individual mineral constituents* on the carbonisation of coal, to which attention had been drawn by Lessing in 1914, has been studied. As the ash in coal cannot be reduced below a certain minimum, sugar and cellulose, practically free from ash, were investigated in the first instance. Forty catalysts have been tried, the compounds being added at the rate of 0·01 gram molecule per 100 grams of sugar or cellulose, either in solution or dry. On carbonising the material by the platinum crucible method for the determination of volatile matter in coal (for three minutes only), remarkable differences in coke yields were found, varying from 20 per cent. to 5 per cent. of the sugar or cellulose, the untreated substance being always at or near the bottom of the list. An attempt was made to group the added compounds according to the magnitude of their [illegible] effect. The quantitative variation is equalled if not surpassed by extraordinary differences in appearance and structure and particularly the swelling propensities in the case of sugar. A preliminary study of coal was made by examining the clarain and vitrain fraction of Dalton Main Coal, the ash of which was reduced to 0·86 per cent. Similar variations were obtained in the yield of coke, retort carbon and tar.

The catalytic influence of inorganic constituents on the carbonisation of coal is therefore proved.

Dr. E. K. Rideal remarked that at least four different effects could be noted from a cursory examination of the authors' results: (*a*) the gaseous catalytic removal of the elements of water by sulphur trioxide; (*b*) the solid catalytic removal of the elements of water by incompletely anhydrous alumina; (*c*) the removal ("peptisation") of the surface film of adsorbed oxygen by alkalis; (*d*) the catalytic partial oxidation of hydrocarbons at the surface of the carbon by catalysts, *e.g.*, iron or manganese, contained therein. It was possible that the catalytic gasification $C + H_2O \rightarrow CO + H_2$ and the subsequent reaction $2CO \rightleftharpoons CO_2 + C$ might also take place.

Dr. Lessing acknowledged the ingenuity of Dr. Rideal's suggestion; he doubted, however, whether there was enough oxygen present to produce the "peptisation" effect referred to. The question of the formation of charcoal which might catalyse volatile substances had been taken into consideration, and the decomposition of hydrogen peroxide by charcoal containing iron was mentioned in the paper.

Mr. R. G. W. Norrish described:—

The photosensitive formation of water from its elements in the presence of chlorine [with E. K. Rideal].

WEIGERT showed qualitatively in 1908 that when a mixture of hydrogen, chlorine, and oxygen is illuminated water is formed. This reaction has been investigated quantitatively at atmospheric pressure in the present research. It has been found that the rate of water formation is given by the expression

$$\frac{d[H_2O]}{dt} = k_1[Cl_2]\,[O_2],$$

it being independent of the hydrogen pressures over a wide range. The reaction resembles the photocatalytic decomposition of ozone in the presence of chlorine, which according to Bodenstein and Bonhoeffer is described by the equation,

$$-\frac{d[O_3]}{dt} = k_2[Cl_2]\,[O_3]$$

It would appear that in both cases chlorine molecules become active by the absorption of visible radiation, and on collision can then transfer their energy either to activate an oxygen molecule or to decompose an ozone molecule. This purely photosensitive process of water formation is regarded as independent of the simultaneous formation of hydrogen-chloride which occurs. The anticatalytic effect of oxygen on the latter reaction is attributed to a direct intervention of oxygen in the hydrogen chlorine reaction chains with their resultant shortening and the formation of a relatively negligible quantity of water.

Prof. H. Brereton Baker suggested that the absorption of hydrogen chloride by slightly moist

phosphorus pentoxide would constitute a source of error; Prof. A. J. Allmand asked whether any measurements of the quantum efficiency of the reaction had been made, and sought information regarding the thermochemical data. Dr. E. K. Rideal did not think that the error envisaged by Prof. Baker would be very great, but admitted the possibility of its existence. He then spoke of the connexion between the experiments described and the Budde effect, referring also to Christiansen and Kramers' hot molecule theory, emphasising the part played in chemical reactions by excited molecules. Dr. T. Slater Price also joined in the discussion.

In reply, Mr. Norrish referred to experiments which had indicated that absorption of hydrogen chloride did not take place; the quantum efficiency of the reaction had not been examined.

Prof. F. L. Pyman then dealt with :—

The directive influence of substituents in the glyoxaline nucleus on substitution in the benzene nucleus of phenylglyoxalines—the nitration of 2-phenylglyoxaline and its carboxylic acids [with E. Stanley].

By the mono-nitration of 2-phenylglyoxaline and its 4-mono- and 4:5-di- carboxylic acids, followed by decarboxylation in the last two cases, the isomeric nitrophenylglyoxalines have been isolated in the following yields :—

	p	*o*	*m*
From 2-phenylglyoxaline ..	50	1·5	0·2
From 2-phenylglyoxaline-4-carboxylic acid	52	—	18
From 2-phenylglyoxaline-4:5-dicarboxylic acid	19	—	52

It is suggested that the results are connected with the fact that the first two compounds form salts with mineral acids, whereas the last does not, and on this basis they may be partly systematised with the help of the theory of induced alternate polarities.

Prof. C. K. Ingold claimed equality of consideration for the alternate polarity theory and Flürscheim's theory of variable affinity in cases where the experimental results could be explained equally satisfactorily by the latter as by the former. Mr. W. E. Garner enquired whether, by working at different concentrations, the possible effect of un-nitrated molecules on the molecules undergoing nitration had been examined. Dr. B. Flürscheim was of opinion that the theory of induced polarities could not consistently explain either Prof. Pyman's experimental results or aromatic substitution in general. The theory assumed that when oxygen and nitrogen are both present, the former is the negative key-atom; thus, in the present case, if the carboxyl oxygen was the key-atom, the anticipation of increased ortho-para orientation resulting from the introduction of carboxyl groups was not borne out by experiment. According to the speaker's own theory, an unsaturated atom directly attached to the nucleus must direct to ortho- and para-substitution. Both theories predicted identical orientation whenever such an unsaturated atom chanced to be relatively electro-negative, and diametrically opposed orientation if otherwise. Where the postulates of the two theories thus disagreed, the theory of induced polarities invariably failed, the positions taken up by substituents entering nitrosobenzene, phenylpropiolic acid and 2.4-dinitroazobenzene being mentioned as examples.

Replying first to a question put by Dr. P. C. Austin, Prof. Pyman said that the fact that the yield of the ortho-compound was very small could probably be attributed to the greater difficulty of its isolation owing to its solubility, and to its greater tendency to oxidation by the nitric acid. Although the polarity theory was not necessarily exclusive in its ability to interpret his results, he considered that mutual neutralisation of the effect of the carbon atoms would be at least as probable as the parallel effect postulated by Dr. Flürscheim in the scheme :—

$$\begin{array}{l} \mathrm{H}\,\overset{-}{\mathrm{O}}\,\overset{-}{\mathrm{O}}\,\overset{+}{\mathrm{C}}\,.\,\overset{-}{\mathrm{C}}\,. \\ \qquad\qquad\;\; \| \\ \mathrm{H}\,\underset{-}{\mathrm{O}}\,\underset{-}{\mathrm{O}}\,\underset{+}{\mathrm{C}}\,.\,\underset{-}{\mathrm{C}}\,. \end{array}$$

Owing to the lateness of the hour, the reading of the paper: Investigations on the dependence of rotatory power on chemical constitution. Part XXIV. Further experiments on the Walden inversion. J. Kenyon, H. Phillips, and H. G. Turley, was postponed until the next meeting of the Society.

MINING IN FRENCH NORTHERN AFRICA

Exports of phosphates from Tunisia in August, 1924, totalled 209,137 metric tons, distributed as follows :—France, 69,630 t., Great Britain, 34,580 t., Belgium, 18,300 t., Italy, 55,377 t., Spain, 2891 t., Portugal, 5920 t., Sweden, 4399 t., and Germany, 8040 t.

In 1923, 190,000 t. of phosphates was exported from Morocco, compared with 80,000 t. in 1922 and 8000 t. in 1921. It is estimated that before very long the railroad and the Casallanca wharves should furnish the means of exporting 450,000 t. a year from Kourigha, or 1500 t. daily. Up to the present the ground actually exploited between El Borrondj and Oned Zem measured about 80 km. in length and 50 km. in breadth, and the deposit of phosphate appears to be 25 to 50 m. in thickness.

The mineral output of Algiers in 1923 amounted to 467,384 t. of phosphates, of which 373,283 t. was won by the Cie. de Phosphates de Constantine, and 59,930 t. by the Cie. des Phosphates de M'Zaita. The output of iron pyrites was 21,000 t.; that of iron ores totalled 1,448,805 t., of which 417,917 t. was extracted by the Société de l'Orienza, 381,531 t. by the Cie. des Mines de fer Magnétique de Mokkta el Hadid, 173,753 t. by the Société des Mines de fer du Zaccar, 101,851 t. by the Société des Mines de fer de Rouina, and 47,145 t. by the Beni Filkai Mining Co., Ltd. Zinc ore won amounted to 61,108 t., and lead ore to 24,475 t. Copper, all extracted by the Cie. Minière et Metallurgique de Caronte, amounted to 2600 t. In addition 1503 t. of antimony and 3562 t. of coal were produced, and the Société Algérienne des pétroles de Thouanet, the sole producers of petroleum, produced 1337 t.

CORRESPONDENCE

THE EARLY HISTORY OF ANTIMONY

Sir,—I have read with some interest Dr. Hyman's paper in *Chemistry and Industry*, dealing with the early history of Antimony in which reference is, of course, made to Basil Valentine. I do not claim to speak with any authority on this matter, but I have always felt that such a person did, in fact, exist, and there appears to be some evidence of his having been

Frontispiece to the 1677 edition of Basil Valentine's Works

born in Mayence [illegible] the end of the fourteenth century, or [illegible] fifteenth century. I have in my [illegible] of Basil Valentine's Works [illegible] published in 1677 [illegible] Hamburg, and [illegible] interesting as the frontispiece gives what [illegible] purports to be a portrait of the [illegible]. This [illegible] which is in German, contains the Tri[illegible] [illegible] y (Triumph-Wagen des Antimonii), [illegible], fairly well known. It is rather earlier [illegible] the Amsterdam edition to which Dr. [illegible], and of which you have reproduced the frontispiece, but there are others much earlier still. I have had the frontispiece photographed and enclose a copy of the photograph as I think it may interest your readers.—I am, Sir, etc.,

A. Chaston Chapman

Sir,—Readers of the article on "The Early History of Antimony," by Dr. Hyman and the subsequent letter by Prof. Partington, may be interested to learn that a copy of the first Latin translation by Kerkringius is contained in the library of the Chemical Society. The illustration reproduced in the article is common to both editions. From a curious defect in the engraving of the date, which makes 1671 to appear as 1674, it is evident that both are from the same plate.

In addition to this volume the library contains an English edition published seventeen years prior to that referred to by Dr. Hyman. The title is, "The Triumphant Chariot of Antimony, being a Conscientious Discovery of the many Reall Transcendent Excellencies included in that Minerall, Written by Basil Valentine, a Benedictine Monke. Faithfully Englished and published for the Common Good. By I. H. Oxon. Printed for Thomas Bruster, and are to be sold at the three Bibles neere the West end of Paules Church-Yard in London. 1660." This edition is very rare, and is not mentioned in any of the bibliographies, and differs from the so-called first edition of 1661 in date and publisher.

It is of interest to note that whilst the title page of the latter edition is a single leaf, that of the 1660 is a part of the first section.—I am, Sir, etc.,

F. H. Clifford

Chemical Society
Burlington House, W. 1
October 20

Sir,—I am obliged to Prof. Partington for his valued criticism of my article of October 10. The editions referred to have escaped experienced bibliographers and are of much interest. The earlier we can trace the history of these books the nearer we will arrive at a solution of their mysteries.

I also take this opportunity of correcting an error in the same paragraph. The translation by A. E. Waite was made in 1893, not 1803.—Yours, etc.,

Glasgow, H. Hyman
October 20, 1924

PERSONAL AND OTHER ITEMS

Mr. S. G. P. Plant, B.Sc., M.A., has been appointed University lecturer in organic chemistry at Oxford.

Mr. H. Lambourne M.A., M.Sc., Senior Lecturer in Organic Chemistry at University College, Nottingham, has been appointed Head of the Chemistry Department at the Borough Polytechnic Institute, London.

The degree of Doctor of Science has been conferred by the University of Glasgow on Mr. Kishori Lal Moudgill, Professor of Chemistry in the College of Science, Trivandrum, South India.

Sir Lees Knowles has been elected Master of the Plumbers' Company.

Dr. W. C. Geer, vice-president in charge of research at the B. F. Goodrich Rubber Co., Ohio, will retire from his post next year with the intention of devoting his time to research.

Dr. A. E. Dunstan has been appointed Chief Chemist to the Anglo-Persian Oil Company, Ltd.

The Institution of Automobile Engineers has awarded its Crompton medal and its "utility prize" to Dr. Aitchison for his paper on "Light alloys for pistons and connecting-rods." The Graduate's prize has been awarded to Mr. R. N. Aveline, of the Coventry Branch, for his paper entitled "Carburation."

Dr. A. T. de Mouilpied, of the British Dyestuffs Corporation, and formerly lecturer in chemistry in the University of Liverpool, has been appointed to the Professorship of Science at the Royal Academy, Woolwich.

On October 20, Prof. H. B. Dixon, honorary professor of chemistry in the University of Manchester, delivered a lecture on "The Life and Work of Ludwig Mond," in the chemistry theatre of the University. The lecture was the first of the "Ludwig Mond lectures," founded by the late Mrs. Ludwig Mond, in memory of her husband. The lectures are to be alternately on pure and applied science.

Dr. R. O. Howell has been appointed lecturer in chemistry in University College, Dundee, in succession to Dr. J. S. W. Boyle, who has become headmaster at Prestonpans. Mr. C. A. Kerr has been appointed assistant in the same chemical department.

Mr. G. J. Robertson has received the Ph.D. degree of the University of St. Andrew's for his thesis, entitled "Investigations on Cellulose."

The following candidates have passed the Examination for the Associateship of the Institute of Chemistry of Great Britain and Ireland :—General Chemistry : Allister, C. F., Heriot-Watt College, Edinburgh ; Austin, R. G., University College, Southampton ; Bell, J. L., Heriot-Watt College, Edinburgh ; Brown, J., Heriot-Watt College, Edinburgh ; Browne, T. E. W., B.Sc., University College, Bangor ; Cochrane, C. G., B.Sc., Heriot-Watt College, Edinburgh ; Firth, H., Bradford Technical College ; Fletcher, A. E., Central Technical School, Liverpool ; Hallas, C. A., B.Sc., Northern Polytechnic Inst. and King's College, London ; Lander, Miss C. M., University College, Nottingham ; McGill, A., Heriot-Watt College, Edinburgh. Ransome, G. L., B.Sc. (Lond.), The University, Cambridge ; Rumford, F., Battersea Polytechnic ; White, W. A., Sir John Cass Technical Institute ; Williams, K. A., B.Sc. (Lond.), Chelsea Polytechnic Institute. Metallurgical Chemistry : Claudet, R. A. O., B.Sc. (Lond.), King's College, London, and Sir John Cass Technical Institute.

The following candidates have passed the Examination for the Fellowship :—Branch "A," Inorganic Chemistry : Morris, E. A., B.Sc. (Lond.). Branch "D," Agricultural Chemistry : Pyne, G. T., A.R.C.Sc.I., B.Sc. (Lond.). Branch "E," the Chemistry, including Microscopy, of Food and Drugs, and of Water : Bagnall, H. H., B.Sc. Branch "G," Chemical Engineering : Sensicle, L. H., B.Sc.

On September 16, a portrait bust in bronze of Louis Pasteur was dedicated in the American Institute of Baking at Illinois. During the ceremony Dr. S. P. L. Sorensen, director of the Carlsberg Laboratories, Copenhagen, Denmark, gave an address on "Louis Pasteur."

Mr. H. Roberts, J.P., a director of Joseph Crosfield and Sons, Ltd., who died in July, left £65,179, with net personalty, £57,394.

The late Mr. C. Haslam, formerly chairman of Joseph Crosfield and Sons, Ltd., and vice-chairman of William Gossage and Sons, Ltd., left £8975, net personalty £6726.

The late Prof. Julius Wertheimer, D.Sc., principal of the Merchant Venturers' Technical College, Bristol, left property valued at £13,693 (net personalty £12,607). A sum amounting to nearly £6000 is left to the Society of Merchant Venturers to found a scholarship at the College.

We regret to announce the death, in a landslide at Kenogami, Quebec, of Sir William Price, president of Price Brothers and Co., Ltd., one of the chief lumber firms in Canada. The firm was founded by Sir William's father, who, sent to Canada from England to procure masts during the Napoleonic blockade, settled in the country and laid the foundations of the modern business, which controls many thousand square miles of pulp and timber areas. The tragic death of Sir William Price is a great loss to the development of Canadian industry, in which he had played a prominent part.

Distillation of Oil Shale in Australia

The Australian Shale Oil Corporation, Ltd., has purchased the rights to the Bronder process of distillation for Australia and New Zealand. The Corporation holds about 3500 acres of shale concessions near Murrurundi, which are estimated to contain 9 million tons of shale, averaging 60 gallons of crude oil to the ton. Five retorts are to be erected, each with a capacity of 22½ tons, and it is estimated that 1000 tons of shale can be treated per day at a cost of 67s. a ton, including charges for mining, transport, retorting and distilling, the oil being valued at over £6 per ton. The chief feature claimed for the Bronder retort is that the charge is uniformly heated, the heat being applied, not to the retort, but to a steel column containing steel tubes and connected with the retort so that the gases from the shale, heated by passing over the tubes, again pass over the shale, which attains 800° F. Initial heating is by producer gas, but when gas is given off this is used for heating.

The Use of Preservatives in Foods

According to the *Grocer*, the report of the committee appointed to inquire into the use of preservatives and colouring matter in food has been presented to the Minister of Health and will be published shortly. It appears that prohibition is recommended of the use of preservatives in food and drink offered for sale, save in specific cases, such as sausages, jam and various beverages. The term preservative is not to apply to salt, saltpetre, sugar, vinegar, acetic acid, alcohol, spices or the agents introduced by smoke-

curing. It is concluded that if preservatives are at all necessary they should consist solely in benzoic and sulphurous acids and their salts. Boric and salicylic acids and their salts, however, are stated to be "not so undesirable as formaldehyde, its derivatives, and fluorides." Most of the articles containing boric acid are said to be sold by other makers free from boric acid. The committee consists of Sir Horace Munro (chairman), Prof. W. E. Dixon, Sir A. D. Hall, Mr. J. M. Hamill, Prof. Gowland Hopkins, Mr. G. R. Leighton, Mr. A. P. Luff, Mr. C. Porter, Mr. E. Richards, and Mr. G. Stubbs.

Notification of Industrial Diseases

In pursuance of sub-section 4 of section 73 of the Factory and Workshop Act, 1901, the Home Office has issued a draft order entitled The Factory and Workshop (Notification of Diseases) Order, 1924, applying to poisoning by carbon disulphide, poisoning by aniline and its compounds, and chronic benzene poisoning occurring in a factory or workshop. The Order is to come into force on January 1, 1925. Copies of the draft Order can be obtained from H.M. Stationery Office, price 1d.

OBITUARY

EDWARD HILTON-BROWN

The death of Mr. Edward Hilton-Brown, F.C.S. which took place with dramatic suddenness from angina pectoris, on September 11, at Toronto, during a special visit to Canada, will be greatly regretted in commercial circles in England, on the Continent and in Canada, where he was highly respected both as a business man and a scientific organiser and experimenter in new methods of manufacture.

Mr. Hilton-Brown was originally a pupil of Sir William Ramsay, who considered him a very prominent student. In the year 1890 he joined the firm W. Miller and Co., of St. Petersburg, leaving them to take up a post as director on the board of Messrs. W. Ropes and Co., oil refiners and distillers, St. Petersburg. During the period 1910-12 Mr. Hilton-Brown distilled oils in what is now known as the "tumble still" with excellent results. Horizontal separators, very closely resembling those erected by one of the most prominent oil companies in England, were used. He also investigated, perfected and then carried out on a commercial scale the hydrolysis of fatty oils and the separation of glycerol by means of naphthenic sulphonic acids at this early period, and did quite a large business in this respect with sunflower-seed oil. Another process brought to the commercial stage and used by Mr. Hilton Brown was the recovery of sulphuric acid from sludge acid. After the separation of the acid tar the acid liquor was diluted and electrolysed. The organic matter present was given off during electrolysis and a water-white concentrated acid of 95 per cent. strength eventually obtained. [illegible] Mr. Hilton-Brown endeared himself [illegible] assistants and, in fact, to everybody who [illegible] contact with him, and, thanks to his genial [illegible] and [illegible] energy, work under his supervision invariably [illegible] on smoothly and well.

REVIEWS

A Systematic Course of Qualitative Analysis. By Henry W. Schimpf, Ph.G., M.D. Fourth edition, revised by Alfred I. Cone, Phar.D., Ph.G. Pp. ix+194. London: Chapman and Hall, Ltd., 1924. Price, 8s. 6d.

This book brings together in a comparatively small space the wide range of work in qualitative analysis required by students of pharmacy, for whom it is primarily intended. The present edition differs from its forerunners in the omission of "short" methods of analysis and in the addition of chapters on ionisation, law of mass action and analysis by the dry method. According to the preface to the first edition, the book is designed for the use of students who have but a few months to spend on a course of analytical chemistry, even though that course comprises the common metals and acids, fatty acids, aromatic acids, coal-tar bases, colouring matters, carbohydrates and alkaloids. This course is made to some extent possible by the care which has been taken by the author and reviser to define the condition necessary for success in the tests described, and the methods for preparing the proper reagents. The best feature of the book lies, in fact, in their definition of experimental conditions.

The section (pp. 97) on "Identification and Separation of Inorganic Acids and Bases"—which, however, deals also with the commoner organic acids—departs very little from standard practice. The reactions and tables are clearly set out, and useful notes, much fuller in many cases than is usual in books of this class, follow the tables. The section on organic analysis (pp. 50) contains a scheme for the detection of a large number of substances of pharmaceutical interest, which appears well designed for its purpose, though of little use for general organic analysis. Even for the purpose in view, the sodium fusion test for nitrogen should have been given in addition to the soda lime test, which would not succeed with several of the substances included in the scheme. In this section, equations and formulae are given only for the simplest reactions and substances, and it is evident that students using the book are expected to acquire little beyond a mechanical system of organic analysis capable of dealing with a particular set of substances.

The section devoted to "definitions and general considerations" (pp. 27) appears to be of very little use. The definitions include several which should be well-known to students before they are permitted to commence qualitative analysis, and one—"Compounds are classified as acids, bases and salts"—which is definitely misleading. The paragraphs on the electrolytic dissociation theory, the law of mass action and the solubility product are clear and concise, but these theories are not applied to explain the methods used in practice. One would hesitate to add to the burden of students who are working through the course described in the book "in a few months"; yet the paragraphs on these theories could only become valuable by the addition of a section in which they were used to explain some of the important separations.

T. S. Moore.

THE RUBBER CONFERENCE—BRUSSELS, 1924. Pp. 218. London: Rubber Growers' Association. Price 5s.

This volume published by the Rubber Growers' Association comprises a series of papers with the discussions thereon read at the Conference held during the recent Rubber Exhibition at Brussels. The subject matter covers a wide field and is mainly concerned with the production and properties of plantation rubber. Of particular note is the paper by Mr. P. J. Burgess which reviews the present-day problems of cultivation, disease, transport and packing of rubber. Prof. Blackman deals with the physiological aspects of disease in plants, an important subject in regard to the disease commonly known as Brown Bast. Dr. Maas analyses the tapping systems in Sumatra. There are two or three papers dealing with chemical and physical research, particularly the vulcanising properties, and including the results of an examination of a new type of raw rubber obtained by spraying latex in hot air. Such rubber is of interest as it is a "whole latex" rubber, whereas the ordinary coagulation process yields rubber from which serum or whey has been removed. There are two or three statistical papers. Mr. Miller deals with the adjustment of production and consumption and Mr. Macfadyen gives abundant data in regard to the development of the industry. The following papers of scientific or technical importance are also of interest, namely, Mr. Pinching on the condition of some of the trees first planted in the East; Dr. Geer (of the B.F. Goodrich Co.) on crude rubber from the consumer's point of view; Drs. Pickles and Turner on the effect of oils on the vulcanisation of rubber; and, finally, Dr. de Vries on the role of enzymes in the coagulation of the Hevea latex.

The book is well got up and clearly printed, has a table of contents and index of authors, but no comprehensive index. The subject matter is from the pen of men well known in the industry who have specialised on the subject discussed. The book should find a place on the shelves of all interested either in crude rubber or its conversion to manufactured articles.

HENRY P. STEVENS

COMPANY NEWS

CELLULOSE HOLDING AND INVESTMENT CO., LTD.

The first dividend of this company, which was formed in 1922, has been declared of 3d. per share, or 25 per cent., tax free.

YADIL PRESS, LTD.

At an extraordinary general meeting on October 21, it was decided to wind up the company, as it "cannot, by reason of its liabilities, continue its business," and to appoint a liquidator.

FORSTERS GLASS CO., LTD.

The fifth annual general meeting was held on October 15, Mr. John Forster (chairman) presiding. Despite the fact that the year had been one of gradually increasing cost of raw materials, rising wages and reduced average price of manufactured goods, the accounts for the year to March 31, 1924, showed a profit of £13,883. This had only been attained by strenuous and efficient work and observing the strictest economy. The number of articles sold during the year was 60 per cent. greater than last year, owing to the opening up of new lines of business, and better trade was expected during the coming months. By adjustments of taxation, the debit balance of £29,292 brought forward last year had been converted into a credit balance of £5529, which, together with the profit of £13,883, made a total credit balance of £19,412, which has been dealt with as follows:—£8247 written off cost of debenture issue; £5000 for depreciation of plant and machinery; £6,165 carried forward.

ROSARIO NITRATE CO., LTD.

An interim dividend of 5 per cent. less tax has been declared.

EASTERN CHEMICAL CO., LTD.

A loss of £5855 is shown by the accounts for the year ended March 31, 1924. In view of the fact that the replacement value of the plant is considerably higher than the original cost, the directors do not consider it necessary to write off any further sum for depreciation this year. Unfavourable conditions recorded in the annual report for last year have continued, and it has not been practicable to raise the prices of the company's manufactures, but very considerable economies have been made in the cost of production, the full effect of which will be felt in the current year.

ALUMINIUM CORPORATION, LTD.

At the fourteenth ordinary general meeting, Mr. Kenneth M. Clark (the chairman), who presided, said that the issued capital stood at the same figure as last year. The first debentures had been increased, after deducting the sinking fund, by £70,370, to provide a portion of the cost of extensions. The second debenture issue was unchanged, and mortgages showed an increase of £200. Loans showed an increase of £11,000 and consisted of £130,000 guaranteed or advanced by the chairman and colleagues, and the sum of £10,000 borrowed from other sources. Sundry creditors and credit balances showed an increase of £13,601, and represented about £53,000 due to ordinary creditors, £12,000 to an associated company, and £86,000 to members of the board, the balance being made up of various reserves for taxation and other contingencies. The sum of £107,903 had been expended during the year on increasing the power and plant, the depreciation reserve on plant and machinery being increased to £34,000. Sundry debtors showed an increase of £23,000, which was in accordance with the increased turnover, whilst stocks were decreased by £32,500. The year 1923 was a less difficult one than 1922, and sales were considerably increased, though, until the end of the period, prices did not improve. The demand for the Corporation's product was maintained in all directions, and the increased

capacity of its rolling mill was fully justified, last year. The Corporation had increased the water storage capacity, and had placed orders for a second and larger pipe-line to take advantage of the increased power. The works were now operating to the full capacity of the plant installed and valuable goodwill had been established. Negotiations had been completed for a tunnel to connect the Eigiau and Cowlyd Lakes, and it was hoped to place the contract for this shortly. This tunnel would greatly help storage and enable the Corporation to balance all their lakes. A dividend of 7 per cent., less income tax, on the preference stock and shares was approved. At the close of the meeting an extraordinary general meeting was held, at which a resolution was passed to convert the existing preference shares into preference stock.

BORAX CONSOLIDATED, LTD.

A dividend of 6 per cent. per annum, less tax, has been declared on the preferred ordinary shares for the half-year ended September 30, 1924. After paying the preference dividend, the preferred ordinary rank for a non-cumulative dividend of 6 per cent., the balance going to the deferred.

BABCOCK AND WILCOX, LTD.

An interim dividend is announced of 5 per cent., tax free, on the ordinary capital of £4,297,656, being the same as was distributed in November last year, when the full dividend, including a 2 per cent. bonus, totalled 12 per cent., against 20 per cent., plus a capitalised bonus of 100 per cent. paid for 1922.

MAGADI SODA CO., LTD.

A meeting was held on October 17, to consider a scheme for the resuscitation of the company, put forward by Messrs. Brunner, Mond and Co., Ltd. Under this scheme the old company would be liquidated and a new company formed which would create and issue £500,000 first mortgage debentures, carrying interest at 6 per cent., payable half-yearly, which were to be redeemable in 1945, or earlier, at six months' notice, but not before July, 1929, at £105 for each £100. The interest on those debentures for the first two financial years of the new company was to be payable out of profits. Each debenture holder was to receive debentures in the new company for the same amount as his present holding. There were various small amendments to the scheme as originally circulated, the chief of which was the redemption price of the debentures. The scheme as modified, was carried; but it was agreed by the meeting that a request should be sent to Messrs. Brunner, Mond and Co., asking them to give more favourable consideration to the deferred shareholders.

The Directors of the Midland Bank, Ltd., announce that they have elected Lord Kylsant, G.C.M.G., to a seat at their Board.

REPORT

Special Reports on the Mineral Resources of Great Britain. Vol. XXVIII. Refractory Materials: Fireclays. Analyses and Physical Tests. By F. R. Ennos, B.A., B.Sc., A.I.C., and Alexander Scott, M.A., D.Sc. Memoirs of the Geological Survey. Pp. 84. H.M. Stationery Office, 1924. Price 3s.

This volume is supplementary to Volume XIV in this series (Refractory Materials: Fireclays. Resources and Geography. Pp. 243. 1920). The data have been principally obtained from analyses at the Geological Survey Laboratories and physical tests made under Dr. Mellor at Stoke-on-Trent, but results have been incorporated which were obtained from other analysts, whose names are given.

The first chapter deals with the general nature of fireclays, which like other clays are formed from pre-existing rocks by disruption accompanied by decomposition and hydration. They may be "residual," that is, lying where formed, or "transported," carried to a fresh bed by the action of water. In the latter case they experience during the translation some sort of grading, and it is this which gives the best clays. In Great Britain the best fireclays are found in association with coal measures and appear to have formed the seat-earth on which the coal-yielding vegetation grew.

Some typical analyses of fireclays are given. They consist essentially of hydrated silica and alumina, which may be free or combined, and which constitute "clay substance," whilst as impurities occur titania, ferric oxide, magnesia, alkalis, and traces of sulphur and organic matter. Some account is given of the mineralogical constitution of clays, a subject which has not received a great deal of attention; the nature of the clay-substance is most reliably discriminated by the behaviour of the clay on heating.

The changes which occur on heating are described, together with factors which spoil the product. The importance of grain-size is mentioned, influencing as it does the rapidity of vitrification and the porosity of the resulting mass.

Chapters II, III, and IV deal respectively with the location, analysis, and results of physical tests of a large number of British fireclays. The analyses were made by the method of W. F. Hildebrand (*Bull.* 700, U.S. Geol. Survey, 1919), except that combined water and organic matter were determined more accurately. The physical tests consisted in determinations of porosity, contraction on firing and drying, and softening point with and without load.

The relation of refractoriness to chemical composition is extremely complicated; some attempts are described, however, to correlate clays of various classes with others in the same class. Clays very seldom conform to the theoretical composition of kaolinite and the silica content may often be usefully adjusted; excess alumina generally increases refractoriness without deleteriously affecting other properties, provided precautions are taken regarding shrinkage and drying. The impurities mentioned above are generally deleterious.

Attempts have also been made to determine the effect of load on refractoriness and also to find some relation between porosity and contraction on firing. The whole Report contains a mass of material of interest to users and manufacturers of bricks and refractories.

LEGAL INTELLIGENCE

ALLEGED INFRINGEMENT OF LETTERS PATENT

Mr. Justice Tomlin, in the Chancery Division on October 16, reserved judgment in an action by Dr. Meyer Wildermann, of Fellows Road, Hampstead, for an injunction to restrain F. W. Berk and Co., Ltd., from infringing his patent (No. 26,568, of 1900) for an invention relating to "improvements in electrolytic cells for the electrolysis of alkaline salts," and for damages.

Mr. Arthur Colefax, K.C. said the plaintiff was a Rumanian, and his complaint was that large quantities of caustic potash were imported which he alleged were made by the Deutsche Wildermann Werke at Luelsdorf, near Cologne, by the use of an apparatus which infringed his invention. The defendants denied infringement and said they did not know of the plaintiff's patent, and that as he was living in Germany when the purchases were made in November and December, 1919, the action was not maintainable owing to the Treaty of Peace of January 10, 1920.

Mr. W. A. Caldwell, analytical chemist, who represented the British Government in Germany in 1919, spoke as to the similarity of the Deutsche Wildermann Werke's plant to that described in plaintiff's specification.

For the defendants Sir D. Kerby submitted that there was no evidence of infringement. The process of preparing the amalgam and making the potash and chlorine, which was the chemical process concerned in this case, was general. What plaintiff had done was to make a small improvement in a cell, but they had nothing to do with that. It would be unfortunate in the public interest, if the plaintiff were to succeed. In 1919, the Government was assisting British trade by arranging sources of supply, and it granted a license to the defendants to import potash. They had no knowledge that plaintiff's patent was used in connexion with its manufacture, and he submitted that it would be harsh to penalise a firm which was simply selling an article, because that article was made by the use of a patent of which it could not have the slightest knowledge. "If I invent a new spade and somebody digs round a fruit tree with it, then anybody who buys the fruit of that tree is an infringer of the patent of my spade." That, he said, appeared to be the result of the plaintiff's argument.

The University of Oxford has agreed to pay sums out of the Government grant for a period of three years to certain college laboratories which undertook part of the University teaching in different departments of chemistry.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech. ..	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	.. £45 per ton.
Powder.. ..	.. £47 per ton.
Acid Hydrochloric	.. 3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	.. £21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric ..	.. Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali..	.. £6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder	.. Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	.. £7 10s. per ton, packages extra. Price advanced.
Borax, Commercial—	
Crystal.. ..	.. £25 per ton.
Powder.. ..	.. £26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	.. £5 17s. 6d. per ton d/d.
Copper Sulphate ..	.. £25 per ton.
Methylated Spirit 64 o.p.—	
Industrial ..	.. 2s. 7d.—2s. 11d. per gallon, according to quantity.
Mineralised ..	.. 3s. 8d.—4s. per gallon, according to quantity.
Nickel Sulphate ..	.. £38 per ton d/d. Normal business.
Nickel Ammon. Sulphate	(as above)
Potash Caustic ..	.. £30—£33 per ton.
Potass. Bichromate	.. $5\frac{3}{4}$d. per lb.
Potass. Chlorate..	.. 3d.—4d. per lb.
Salammoniac ..	.. £32 per ton d/d.
Salt Cake.. ..	.. £3 10s. per ton d/d.
Soda Caustic, solid	.. Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals ..	.. £5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	.. £24 per ton.
Sod. Bicarbonate	.. £10 10s. per ton, carr. paid.
Sod. Bichromate..	.. $4\frac{1}{4}$d. per lb.
Sod. Bisulphite Powder 60/62%.. ..	.. £17—£18 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate ..	.. 3d. per lb.
Sod. Nitrate refd. 96%	.. £13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. 60/65	About £14 10s. per ton /dd.
Sod. Sulphide cryst.	.. £9 per ton d/d.
Sod. Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	.. 6½d.—1s. 2d. per lb., according to quality.
Crimson ..	.. 1s. 4d.—1s. 6d. per lb., according to quality.
Arsenic, Sulphide, Yellow	1s. 11d. per lb.
Barytes	.. £3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	.. 3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide	.. £30—£33 per ton, according to quantity.
Carbon Black ..	.. 7d.—7½d. per lb. ex wharf.
Carbon Tetrachloride	.. £60—£65 per ton, according to quantity, drums extra.
Chromium Oxide, green ..	1s. 3d. per lb.
Indiarubber Substitutes White and Dark ..	5d.—9½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black ..	.. £48 per ton, barrels free.
Lead Hyposulphite	.. 7½d. per lb.
Lithopone, 30% ..	.. £22 10s. per ton.
Mineral Rubber "Rubpron"	.. £16 5s. per ton f.o.r. London.
Sulphur	.. £10—£12 per ton, according to quality.
Sulphur Precip. B.P.	.. £47 10s.—£52 10s. per ton, according to quantity.
Sulphur Chloride	.. 4d. per lb., carboys extra.
Thiocarbanilide ..	.. 2s. 6d. per lb.
Vermilion, pale or deep ..	5s. 1d. per lb.
Zinc Sulphide ..	.. 7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

There is a general feeling that the fall in price of acetates during the last few weeks has reached its limit. The tendency is now to stiffen again.

Acetate of Lime—	
Brown	.. £11—£11 10s. per ton.
Grey	.. £15 per ton.
Liquor	.. 9d. per gall. 32° Tw.
Charcoal	.. £7 15s.—£9 5s. per ton, according to grade and locality. Demand quiet but price steady.
Iron Liquor ..	.. 1s. 7d. per gall. 32° Tw.
	1s. 2d. ,, ,, 24° Tw.
Red Liquor ..	.. 10d.—1s. per gall. 14/15° Tw.
Wood Creosote ..	.. 2s. 9d. per gall. Unrefined.
Wood Naphtha—	
Miscible ..	.. 4s. 9d. per gall. 60% O.P.
Solvent	.. 5s. 6d. per gall. 40% O.P. Firmer.
Wood Tar ..	.. £4 5s. per ton. Very quiet.
Brown Sugar of Lead	.. £43 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals ..	.. 6¼d.—6½d. per lb. Quiet.
Crude 60's ..	.. 1s. 9d. per gall. Market flat.
Acid Cresylic, 97/99	.. 2s.—2s. 1d. per gall. Demand fair.
Pale 95% ..	.. 1s. 10d.—2s. per gall. Better enquiry.
Dark	.. 1s. 9d.—2s. per gall. Fairly steady.
Anthracene Paste 40%	.. 4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained ..	.. 6¼d.—6½d. per gall. Small demand.
Unstrained ..	.. 6d.—6¼d. per gall.
[illegible]	
[illegible] 65's ..	.. 7½d.—9d. per gall. ex works in tank wagons.
Benzole—	
Standard Motor	.. 1s. 1½d.—1s. 3d. per gall. ex works in tank wagons.
Pure	.. 1s. 5½d.—1s. 7d. per gall. ex works in tank wagons.
Toluole—90% ..	.. 1s. 5d.—1s. 5½d. per gall. Small demand for home consumption.
Pure ..	.. 1s. 8d.—1s. 9d. per gall. Small demand for home consumption.
Xylol—Coml. ..	.. 2s. 3d. per gall.
Pure ..	.. 3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	.. 8½d. per gall. Little demand.
Middle Oil .. / Heavy Oil .. / Standard Specification	5d.—6½d. per gall., according to quality and district. Fair business passing. A little more demand for export in bulk.
Naphtha—	
Solvent 90/160	.. 1s.—1s. 3d. per gall. Demand good.
Solvent 90/190	.. 11d.—1s. per gall. Fair inquiry. Local demand good.
Naphthalene Crude—	
Cheaper in Yorkshire than Lancashire. Demand rather better.	
Drained Creosote Salts	£2 15s.—£5 10s. per ton. Very dull. No demand.
Whizzed or hot pressed	£6—£9 per ton. Demand very poor.
Naphthalene—	
Crystals and Flaked	.. £12—£15 per ton, according to district.
Pitch, medium soft	.. 40s.—45s. per ton f.a.s. Plenty of inquiry. Prospects brighter. Price too low to interest the distillers.
Pyridine—90/160	.. 19s. per gall. Steady demand.
Heavy	.. 12s.—12s. 6d. per gall. Market dull.

INTERMEDIATES AND DYES

Normal business in dyestuffs has been maintained this week, and users seem to have more confidence. Slight reductions have been made in the price of a number of intermediates.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	.. 1s. 7d. per lb.
Acid H.	.. 3s. 11d. per lb. 100% basis d/d.
Acid Naphthionic	.. 2s. 2d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	.. 1s. 1d. per lb. Improved demand.
Acid Sulphanilic	.. 9d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil ..	.. 8d. per lb. naked at works.
Aniline Salts ..	.. 8½d. per lb., naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base ..	.. 3s. 11d. per lb. 100% basis d/d.
Benzyl Chloride 95%	.. 1s. 1d. per lb.
p-Chlorphenol ..	.. 4s. 3d. per lb. d/d.
p-Chloraniline ..	.. 3s. per lb. 100% basis.
o-Cresol 19/31° C.	.. 4½d. per lb. Rather quiet.
m-Cresol 98/100%	.. 2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	.. 2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline ..	.. 3s. per lb.
Dichloraniline S. Acid	.. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol ..	.. £85 per ton.
Diethylaniline ..	.. 4s. 3d. per lb. d/d., packages extra, returnable.
Dimethylaniline ..	.. 2s. 2½d. per lb. d/d. Drums extra.
G Salt ..	.. 2s. 4d. per lb. 100% basis d/d.

α-Naphthol	2s. 5d. per lb. d/d.
Dinitrobenzene	9d.—10d. per lb. naked at works.
Dinitrochlorbenzol ..	£84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine	2s. 10d. per lb. d/d.
Monochlorbenzol.. ..	£63 per ton.
β-Naphthol	1s. per lb. d/d.
α-Naphthylamine ..	1s. 3½d. per lb. d/d.
β-Naphthylamine ..	4s. per lb. d/d.
m-Nitraniline	4s. 2½d. per lb. d/d.
p-Nitraniline	2s. 2½d. per lb. d/d.
Nitrobenzene	5½d.—5¾d. per lb. naked at works.
o-Nitrochlorbenzol ..	2s. 11d. per lb. 100% basis d/d.
Nitronaphthalene ..	10½d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine ..	3s. 10d. per lb. d/d.
p-Phenylene Diamine ..	10s. 2d. per lb. 100% basis d/d.
R. Salt	2s. 4d. per lb. 100% basis d/d.
Sodium Naphthionate ..	2s. 2d. per lb. 100% basis d/d.
o-Toluidine	10d. per lb.
p-Toluidine	3s. per lb. naked at works.
m-Toluylene Diamine ..	3s. 10d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS.

Acid, Acetic 80% B.P. ..	£47 per ton. Firmer.
Acid, Acetyl Salicylic ..	3s. 1d.—3s. 3d. per lb., according to quantity. Sales steady. Price firm.
Acid, Benzoic B.P. ..	2s. 6d. per lb. Cheaper.
Acid Boric B.P.	Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric.. ..	19s.—21s. per lb.
Acid, Citric	1s. 3½d.—1s. 4½d. per lb., less 5% for ton lots. Market very weak.
Acid, Gallic	2s. 9d. per lb. for pure crystal in 2 cwt. lots.
Acid, Pyrogallic, Cryst. ..	6s. 9d. per lb. Resublimed quality 8s. per lb. Market firm.
Acid Salicylic	1s. 6d.—1s. 8d. per lb., according to quantity.
Acid, Tannic B.P. ..	2s. 10d. per lb. Market quiet.
Acid, Tartaric	1s. 1½d. per lb. less 5%.
Amidol	9s. per lb. d/d.
Acetanilide	2s. per lb. for quantity. More enquiry.
Amidopyrin	16s. 6d. per lb. for spot stocks.
Ammon. Benzoate ..	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate ..	12s. 6d. per oz. for English make.
Barbitone..	14s. 3d. per lb.
Bismuth Carbonate ..	10s. 6d.—12s. 6d. per lb.
" Citrate.. ..	10s. 3d.—12s. 3d. "
" Salicylate ..	9s.—11s. "
" Subnitrate ..	8s. 8d.—10s. 8d. "
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	Marker firm. Prices advancing.
Ammonium	1s. 6d.—1s. 9d. per lb. } According to quantity.
Potassium	1s 4d.—1s. 7d. per lb. }
Sodium	1s. 5d.—1s. 8d. per lb. }
Calcium Lactate ..	1s. 5d.—1s. 7d. per lb., according to quantity. Fair demand and steady market.
Chloral Hydrate	4s.—4s. 3d. per lb. Slightly dearer. Spot supplies short.
Chloroform	2s. per lb. for cwt. lots. Very steady.
Formaldehyde	£48 per ton in barrels, ex wharf London.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free	7s. per lb.
Glycerophosphates—	
Iron	8s. 9d. per lb.
Magnesium	9s. per lb.
Potassium, 50% ..	3s. 6d. per lb.
Sodium, 50%	2s. 6d. "
Guaiacol Carbonate ..	10s. per lb.
Hexamine	3s. per lb. Forward prices higher.
Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor ..	English make offered, 120s. per oz.
Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. "
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb.
Magnesium Carbonate—	
Light Commercial ..	£36 per ton net.
Magnesium Oxide—	
Light Commercial ..	£75 per ton, less 2½%.
Heavy Commercial ..	£25 per ton, less 2½%.
Heavy Pure	2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst, B.P. ..	55s. per lb. Price shows signs of recovery.
Synthetic	26s.—35s. per lb., according to quantity. English make. Increasing demand.
Mercurials	Market very quiet.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate ..	3s. 6d.—3s. 7d. "
White precip.	4s. 7d.—4s. 8d. "
Calomel	3s. 11d.—4s. "
Methyl Salicylate ..	1s. 10d.—2s. per lb. Seasonal increase in demand.
Methyl Sulphonal ..	24s. per lb. Slightly weaker.
Metol	11s. per lb. British make.
Paraformaldehyde ..	2s. 8d. per lb. for B.P. quality.
Paraldehyde	1s. 4d.—1s. 6d. per lb. in free bottles and cases. Supplies plentiful.
Phenacetin	5s. 9d. per lb.
Phenazone	7s. per lb.
Phenolphthalein	5s. 9d. per lb.
Potass. Bitartrate— 99/100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots.
Potass. Citrate	1s. 10d.—2s. 2d. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Steady market.
Potass. Metabisulphite ..	7½d. per lb., 1-cwt. kegs included. F.o.r. London.
Potass. Permanganate ..	7¾d. per lb. spot. Forward prices higher.
Quinine Sulphate ..	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Saccharin	63s. per lb., in 50-lb. lots.
Salol	3s. 9d. per lb. for cwt. lots.
Sod. Benzoate, B.P. ..	2s. 6d. per lb. Supplies of good quality now available.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite— Photographic	£13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.

Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.	
Sod. Nitroprusside	16s. per lb.	
Sod. Potass. Tartrate (Rochelle Salt)	75s.—82s. 6d. per cwt., according to quantity. Quiet market.	
Sod. Salicylate	Fair demand. Powder 2s.—2s. 3d. per lb. Crystal at 2s. 2d.—2s. 5d. per lb. Flake 2s. 6d. per lb.	
Sod. Sulphide—		
Pure recryst.	10d.—1s. 2d. per lb.	
Sod. Sulphite, anhydrous	£27 10s. per ton, minimum 5-ton lots, increasing according to quantity, 1-cwt. kegs included.	
Sulphonal	15s. 6d. per lb.	Little demand.
Thymol	17s. 6d. per lb.	

PERFUMERY CHEMICALS

Acetophenone	12s. per lb.	Cheaper.
Aubepine	15s. 3d. ,,	
Amyl Acetate	2s. 9d. ,,	Dearer.
Amyl Butyrate	6s. 9d. ,,	
Amyl Salicylate	3s. 3d. ,,	
Anethol (M.P. 21/22° C.)	4s. 6d. ,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 9d. ,,	
Benzyl Alcohol free from Chlorine	2s. 9d. ,,	
Benzaldehyde free from Chlorine	3s. 6d. ,,	
Benzyl Benzoate	3s. 6d. ,,	
Cinnamic Aldehyde—		
Natural	18s. 9d. ,,	
Coumarin	19s. 6d. ,,	
Citronellol	17s. ,,	
Citral	8s. ,,	
Ethyl Cinnamate	12s. 6d. ,,	
Ethyl Phthalate	3s. 3d. ,,	
Eugenol	10s. ,,	
Geraniol (Palmarosa)	33s. 6d. ,,	
Geraniol	11s. 6d.—18s. 6d. per lb.	
Heliotropine	6s. 9d. ,,	
Iso Eugenol	15s. 9d. ,,	
Linalol ex Bois de Rose	26s. ,,	
Linalyl Acetate	26s. ,,	
Methyl Anthranilate	9s. 6d. ,,	
Methyl Benzoate	5s. ,,	
Musk Ambrette	50s. ,,	
Musk Xylol	13s. 6d. ,,	
Nerolin	4s. 9d. ,,	
Phenyl Ethyl Acetate	15s. ,,	
Phenyl Ethyl Alcohol	16s. ,,	
Rhodinol	55s. ,,	Cheaper.
Safrol	1s. 10d. ,,	
Terpineol	2s. 4d. ,,	
Vanillin	25s. 6d. ,,	

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.	
Anise Oil	2s. 8d. per lb.	
Bergamot Oil	16s. 6d. per lb.	
Bourbon Geranium Oil	33s. 6d. per lb.	Cheaper.
Camphor Oil	65s. per cwt.	
Cananga Oil Java	10s. per lb.	
Cinnamon Oil, Leaf	6½d. per oz.	
Cassia Oil, 80/85%	9s. 9d. per lb.	
Citronella Oil—		
Java [illegible]%	5s. 9d. per lb.	
Ceylon	3s. 6d. per lb.	Dearer.
Clove Oil	7s. 9d. per lb.	Dearer.
Eucalyptus Oil 70/75%	2s. 3d. per lb.	
Lavender Oil—		
French 38/40% Esters	28s. 6d. per lb.	
Lemon Oil	3s. 2d. per lb.	Dearer.
Lemongrass Oil	4s. 6d. per lb.	
Orange Oil, Sweet	11s. per lb.	
Otto of Rose Oil—		
Bulgarian	40s. per oz.	
Anatolian	18s. per oz.	
Palma Rosa Oil	16s. 6d. per lb.	
Peppermint Oil—		
English	65s. per lb.	
Wayne County	30s. per lb.	Higher prices anticipated.
Japanese	18s. per lb. paid.	Practically unobtainable for spot or near delivery.
Petitgrain Oil	9s. 3d. per lb.	
Sandal Wood Oil—		
Mysore	26s. 7d. per lb.	
Australian	18s. 6d. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before Dec. 15th; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on October 30th.

I.—Applications

Freeman. Furnaces. 23,573. Oct. 6.

Harrold. Furnaces. 23,758. Oct. 8.

Hurrell. Apparatus for producing emulsions etc. 23,509. Oct. 6.

Millar. Crushing rollers. 23,805. Oct. 8.

Nyrop. Apparatus for atomising liquids. 24,078. Oct. 10.

Paterson. Apparatus for treating liquids with chemical reagents etc. 23,836. Oct. 8.

Rosencrants, and Vickers and International Combustion Engineering Co., Ltd. Furnaces. 23,572. Oct. 6.

I.—Complete Specifications Accepted

14,200 (1923). Hoevan. Mixing substances. (199,739.)

17,247 (1923). Tone. Ovens or furnaces. (200,606.)

25,093 (1923). Lilleshall Co., Ltd., and Bishop. Centrifugal filters, separators, etc. (222,676.)

15,590 (1924). Roberts. Centrifugal separator baskets. (218,321.)

II.—Applications

Crozier. Vertical retorts for distillation of shale etc. 23,689. Oct. 7.

Hérengt. Agglomerate fuel. 24,083. Oct. 11.

Hérengt. Distillation of fuel. 24,084. Oct. 11.

Laing and Nielsen. Distillation of carbonaceous materials. 24,048. Oct. 10.

Mayer (Ornstein). Manufacture of lampblack and soot. 23,739. Oct. 7.

Naamlooze Vennootschap Philips' Gloeilampenfabrieken. Precipitating chemical compounds on an incandescent body etc. 24,076. Oct. 10. (Holland, 11.10.23)

Parker and Jones. Distillation of coal etc. 23,743. Oct. 7.

Rosencrants, and Vickers and International Combustion Engineering, Ltd. Drying coal etc. 23,724. Oct. 7.

Trent. Process for producing metallurgical coke. 23,578. Oct. 6. (U.S., 6.10.23.)

Gas Light and Coke Co. and Eve. Gas scrubbers and washers. 23,717. Oct. 7.

II.—Complete Specifications Accepted

17,143 (1923). Wade (Philips' Gloeilampenfabrieken). Electrodes for electric discharge tubes. (222,561.)

17,681 (1923). Bone and Finch. *See* VII.

21,022 (1923). Christenson. *See* VII.
24,848 (1923). Kohlenveredlung Ges. Distillation of carbonaceous substances. (205,101.)
27,791 (1923). Soc. Ricard, Allenet et Cie. Fuels comprising alcohol and liquid hydrocarbon. (206,516.)
28,928 (1923). Evans (Ges. für Maschinelle Druckentwasserung). Agglomeration of coal, coke, ore, etc. (222,702.)
7483 (1924). Ramage. Low-temperature distillation. (214,222.)

III.—Application

James (Lignojen Maschinen und Apparatebau Ges.). Tar separators. 23,738. Oct. 7.

IV.—Complete Specifications Accepted

17,389 (1923). Soc. of Chemical Industry in Basle. Manufacture of sulphurised dyestuffs and intermediate products. (201,540.)
20,925 (1923). Soc. of Chemical Industry in Basle, Reber, and Froehlich. Manufacture of sulphurised dyestuffs and intermediate products. (222,624.)

V.—Applications

British Celanese, Ltd. and Ellis. Treatment of cellulose derivatives. 23,816. Oct. 8.
Ehrenthal and Scholz. Production of cottonised fibres. 23,721. Oct. 7.

V.—Complete Specification Accepted

16,963 (1923). Lilienfeld. Cellulose solutions. (217,166.)

VI.—Applications

Huebner. Finishing and ornamentation of textile materials. 23,983. Oct. 10.
Hunt, Parker, and Moscrop, Ltd. Dyeing machines. 23,990. Oct. 10.
Lord. Apparatus for treating hanks of yarn with liquids. 23,781. Oct. 8.

VI.—Complete Specifications Accepted

9192 (1923). Standard Silk Dyeing Co. Washable dye silk piece goods, and processes of dyeing same. (207,776.)
9196 (1923). Harrington. Waterproofing fabric articles. (222,292.)
17,228 (1923). Scholz. Dyeing textile fabric, paper, etc. (222,567.)
23,740 (1923). Schlumpf. Dyeing apparatus. (217,875.)
17,719 (1924). Standard Silk Dyeing Co. Washable dyed silk piece goods, and a process of dyeing same. (219,697.)
18,339 (1924). Standard Silk Dyeing Co. Dyeing silk black. (219,995.)

VII.—Applications

Cederberg. Catalytic combustion of ammonia-oxygen mixtures. 23,708. Oct. 7. (Ger., 4.12.23.)
Naamlooze Vennootschap Philips' Gloeilampenfabrieken. Manufacture of hafnium and zirconium compounds. 24,125. Oct. 11. (Holland, 15.11.23.)

VII.—Complete Specifications Accepted

17,681 (1923). Bone and Finch. Recovering ammonia from gases or vapours. (222,587.)
21,022 (1923). Christenson. Producing ammonium chloride from gases. (211,096.)
21,099 (1923). Noll. Manufacturing durable compounds containing active oxygen. (202,985.)
24,911 (1923). Angel. Making pure table salt in conjunction with electrolysis of salt solutions. (205,103).
30,874 (1923). Ewan. Manufacture of alkali metal amides. (222,718.)

VIII.—Applications

Brookes. Saggers for firing pottery. 23,875. Oct. 9.
Reynolds. Glazing of tiles etc. 24,151. Oct. 11.

IX.—Applications

Boorne and Budde. Building material etc. 24,134. Oct. 11.
Evers. Cement kilns. 23,956. Oct. 9.

X.—Applications

Brown. Extraction of metals from their ores. 23,605. Oct. 6.
Coley and Hornsey. Production of iron from iron ores. 24,000. Oct. 10.
Gerdts. Alloying metals. 23,707. Oct. 7.
Trent. 23,578. *See* II.

X.—Complete Specifications Accepted

11,759 (1923). Marks (Eureka Metallurgical Co.), Concentrating oxidised ores by flotation. (222,530.)
17,163 (1923). Jonas and Hunt. Annealing - furnaces. (222,566.)
17,417 (1923). Speck and Kennedy. Furnaces for annealing and tempering. (222,575.)
28,928 (1923). Evans (Ges. für Maschinelle Druckentwasserung). *See* II.
30,367 (1923). Heddernheimer Kupferwerk. Alloys suitable for pressed or cast bearings. (207,826.)
3670 (1924). Stehli. Apparatus for sintering and otherwise treating ores. (222,748.)
6929 and 6985 (1924). Allmanna Ingeniorsbyran H. G. Torulf. Sintering fine and pulverous ores. (220,924, 220,925.)

XI.—Application

Kalling. Electric resistance furnace. 23,593. Oct. 6.

XI.—Complete Specifications Accepted

24,911 (1923). Angel. *See* VII.
28,872 (1923). Monnot. Alkaline storage batteries. (222,701.)
2389 (1924). Tribelhorn. Filling-paste for secondary elements. (210,777.)
10,450 (1924). Ridoni, and Soc. Talco e Grafiti val Chisone. Manufacture of electrodes from natural graphites. (222,785.)

XIII.—Application

Mayor (Ornstein). 23,739. *See* II.

XIII.—Complete Specification Accepted

17,278 (1923). Lloyd, Clapp, and Campbell. Manufacture of white lead. (203,301.)

XIV.—Applications

Bezenecenet. Impregnation of material with rubber etc. 24,088. Oct. 11.
Etty and Wilby. 23,863. *See* XV.

XV.—Applications

Etty and Wilby. Production of chrome leather. 23,862. Oct. 8.
Etty and Wilby. Manufacture of rubberised hides etc. 23,863. Oct. 3.
Kaye, Lloyd, and Pickard. Production of hide and chrome leather power for tannin analysis. 23,968. Oct. 9.

XVIII.—Complete Specification Accepted

16,740 (1923). Norbury, Desborough, Thaysen, and Galloway. Treating vegetable matter by fermentation to obtain alcohol, acetone, etc. (222,549.)

XIX.—Applications

Carpmael (Bayer und Co.). Exterminating vermin. 24,065. Oct. 10.
Harold. Preparation etc. of sterilising-agents, germicides, etc. 23,748. Oct. 7.

XX.—Applications

Knoll und Co. Preparation of dihydrocodeinone from thebaine. 23,835. Oct. 8. (Ger., 7.12.23.)
Welter. Manufacture of fatty acids. 24,052. Oct. 10. (Ger., 23.10.23.)

XX.—Complete Specification Accepted

16,740 (1923). Norbury, Desborough, Thaysen, and Galloway. *See* XVIII.

XXI.—Application

Proszynski. Photographic film. 23,683. Oct. 7.

XXI.—Complete Specification Accepted

9415 (1923). Martinez. Direct - colour photography. (222,523.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department, and quoting the specific reference number :—*Argentina* : Iron and steel, cement (429) ; *Canada* : Chemicals (403) ; Rubber goods (404) ; Stainless steel sheets, talc (The Canadian Government Trade Commissioner's Office, Portland House, 73, Basinghall Street, London, E.C. 2) ; *Chile* : Tinplate, silk (430) ; *Egypt* : Iron, brass (416) ; *France* : Chemical products (411) ; *Latvia* : Copper (A.X./1371) ; *New Zealand* : Steel (406) ; *Norway* : Chemicals, oils (413) ; *South Africa* : Steel (A/1376) ; Aluminium paint (B.X./1287) ; *Spain* : Drugs, anilines, colours, chemicals (414) ; *Sweden* : Leather (415) ; *United States* : Leather (420) ; leather (425) ; *Venezuela* : Hardware (434) ; *Yugoslavia* : Tinplate (412) ; X-Ray apparatus (B.X./1276).

Notes on Plant and Products

Bells United Asbestos Co., Ltd., has issued a pamphlet (reprinted from the *Indiarubber Journal*) entitled, "The development of the asbestos industry (1871–1924)." The early uses of asbestos, and the commencement of the modern interest in asbestos are briefly dealt with, the history of the industry being reviewed up till the formation of the United Asbestos Company in 1879, by the amalgamation of the Glasgow and Italo-English Companies and the asbestos interests of Messrs. Furse Bros. Further important developments took place in 1909, when the business of Bell's Asbestos Co., Ltd., and of the United Asbestos Co., Ltd., were amalgamated under the name of "Bell's United Asbestos Co., Ltd., and the manufacturing operations of Bell's Company in Southwark Street and East Greenwich were transferred to the United Company's factory at Harefield, which was remodelled and extended to meet the new requirements. A gen[illegible]l survey of the progress which the industry ha[illegible] made during the past fifty years is also given, together with a description of the multitudinous uses of asbestos, including brake and clutch linings, and the British-Asbestos-Cement tile, a product of the Patents Act of 1907. For some years after asbestos was introduced to the engineering world (about 1871 or 1872) it was thought that where resistance to heat and steam was essential, asbestos would take the place of rubber, but experiments have proved that intelligent combination between the two articles has obtained th[illegible]est results.

The British Sul[illegible] Ammonia Federation, Ltd. announces that th[illegible] for November delivery is £14 6s. per ton, a[illegible] December delivery, £14 8s. per ton, for neutr[illegible]uality in fine friable condition, free from lumps, [illegible]sis 21·1 per cent. nitrogen, in 4-ton lots. Limited quantities of ordinary quality will be ava[illegible] in some districts, and will be sold at 23s. per t[illegible] than the above prices, basis 20·7 per cent. ni[illegible] Neutral sulphate of ammonia as describ[illegible]ve, guaranteed not to contain more than 0[illegible] cent. free acid, will be sold on the basis of 21·1 per cent. nitrogen, with no charge if over 21·1 per cent., but with a rebate of 1s. 6d. for every decrease of 0·10 per cent. of nitrogen. An allowance of 9s. 6d. per ton will be made if the content of free acid exceeds 0·025 per cent., and an allowance of 9s. 6d. will also be made, should any delivery of neutral sulphate not be in fine friable condition free from lumps. Ordinary sulphate of ammonia will be sold on the basis of 20·7 per cent. nitrogen, with no charge if over 20·7 per cent., but with an allowance of 1s. 6d. for every decrease of 0·10 per cent. of nitrogen. These qualitative deductions apply only to deliveries of two cwts. and over.

The Consett Iron Co., Ltd., is considering developments which include the duplication of the new American Fell coke works, the remodelling of the Templetown coke works, and the erection of a large by-product plant near Newcastle. The reconstruction of the steel works will be complete in January, and the Company will then employ roughly 6000 more men than in 1913.

A new artificial-silk factory is to be built for Courtaulds, Ltd., at Bushbury, Wolverhampton. It is stated that the cost will be £1,500,000.

Overseas Trade

The *Board of Trade Journal* states that the declared values of imports during the September quarter of the year were 2·5 per cent. higher than during the third quarter of 1923, and the quantities of goods imported 22·2 per cent. higher. Exports of United Kingdom goods show a small reduction in average declared values of 1·1 per cent., and an increase in quantities shipped representing in the aggregate, 10·7 per cent.

PUBLICATIONS RECEIVED

A Classified Catalogue of Works Published by Messrs. Longmans, Green and Co. Pp. xliv+196. London: Longmans, Green and Co., 1924.

The Principles of Applied Electro-Chemistry. By A. J. Allmand, M.C., D.Sc. Second edition, revised and enlarged by the author and H. J. T. Ellingham. Pp. x+727. London: E. Arnold and Co., 1924. Price 35s. net.

Distillation du Bois. By G. Dupont. Encyclopedie Leaute. Pp. xv+284. Paris: Gauthier-Villars & Cie., 1924. Price 25 fr.

The Enlarged Callendar Steam Tables (Fahrenheit Units). By H. L. Callendar, C.B.E., F.R.S. Pp. 80. London: E. Arnold and Co., 1924 Price 7s 6d.

The Corrosion of Metals. By U. R. Evans, M.A. Pp. xii+212. London: E. Arnold and Co., 1924. Price 14s.

Messrs. G. Bell and Sons, Ltd., announce the publication, in the autumn, of the following books :—"Concerning the Nature of Things," by Sir W. Bragg, and "Chats on Science," by Prof. E. E. Slosson. Books published recently by the same firm include new editions of "X-rays and Crystal Structure," by Sir W. H. Bragg and Prof. W. L. Bragg, and "Webster's New International Dictionary."

The Chemical Society, the Society of Chemical Industry, the Association of British Chemical Manufacturers, the Institute of Chemistry, the Society of Public Analysts, the Faraday Society, the Institute of Brewing, the Society of Dyers and Colourists, the Society of Glass Technology, the Iron and Steel Institute, the Ceramic Society, the Institution of Gas Engineers, the Society of Leather Trade Chemists, the Royal Photographic Society, the Mineralogical Society, the Biochemical Society, the Institute of Metals and the Royal Agricultural Society.

VOL. 43 NEW SERIES | LONDON, OCTOBER 31, 1924 | NO. 44

EDITORIAL

DR. LUDWIG MOND, the subject of Prof. Dixon's recent lecture, was a remarkable man. He was remarkable in very many respects; he was an excellent chemist with a scientific mind, and able to exercise a sound judgment when faced by a scientific problem. He was also an extremely determined man; when he made up his mind to do a particular thing, for instance to make a particular piece of plant work as it should, he did not allow difficulties—whether they took the form of men, of defects, of delays, or of ignorance—to stand in his way. He persevered with his task in the face of difficulties which were nearly insuperable until it was accomplished. He had remarkable luck; that sort of luck which consists in getting up at six o'clock in the morning, in spending half-a-crown when other men spend half-a-sovereign, and in minding your own business. We do not remember that he had any other sort of luck. He was as thorough as he was determined; he had an iron will and, until late in life, he had an iron constitution. And yet he had a kindly and generous nature; a love of art and all things artistic; an appreciation of good pictures, good music and good literature, and a certain simplicity characteristic of many of the kindly Germans who lived fifty years ago. We never knew him when in his prime; we suspect that during that period of his life he must have been singularly energetic and autocratic, as are most men who accomplish great things. He also had the gift of obtaining and keeping the friendship of other men who, very different from him in their nature and training, were invaluable in the enterprises in which they were associated. It is a good thing that his memory should be kept alive by such a scheme of lectures as that instituted by the late Mrs. Mond.

The report of the meeting of the Yorkshire Section of the Society of Chemical Industry is of unusual interest. An appeal was then made for more articles on present chemical trade problems. There may be a difference of opinion about some features of the *Journal*, for instance, the editorials, but there is no difference of opinion about articles on chemical trade problems. The Yorkshire Section wants more of these, so does the editorial department of *Chemistry and Industry*; so does the editorial department of the *Transactions*, so does, in fact, every reader of the *Journal*. It was said in old days of Lockyer that he sometimes forgot that he was the editor and not the creator of Nature! We beg our readers to remember that we are merely editors. We hear many items of news, fresh developments in industry, new processes, and so on, always accompanied by the condition that no information is to be made public until further notice. This hampers us very greatly in our sanctum; on the other hand, there are several thousand chemists engaged in industry, whose knowledge is adequate for the purpose, who could send us articles of the type we all desire. We are grateful for these; they form suitable subjects for the meetings of our sections. We have no cabinet full of such articles waiting for the day when we can rouse ourselves from our lethargy sufficiently to hand them to the printers. To put the matter baldly and bluntly, we want such articles. Had we more of them we could avoid spending time on writing rather garrulous paragraphs of hardly even ephemeral interest. If every section would send us even only one such article within the next two months we should have a supply which would keep us going until our columns are filled with accounts of York Minster, and a visit to the paint and varnish factories at Ripon, with incidental notes about Fountains Abbey and Brimham Rocks. Keep us supplied with really nutritive matter until we can refresh our minds on the banks of the Nidd or the Skell, watch the Yore tumbling down at Aysgarth,

or listen to the jackdaws disporting themselves over the Wharfe at Boston Spa.

* * *

We have in the past commented on the fact that chemists here do not take the same interest in public affairs that is taken by some other professions in which men engage. It is different, it seems, in America. The Chemists' Coolidge and Dawes Committee is hard at work there; the literature sent out by the committee appeals very strongly; we have read it and much like it. It is, however, so complicated a situation that it is not easy for the chemists over here to make up their analytical minds. Here there are two sides to every question, and our side is right and yours is wrong. Over there the problem is not so simple; we asked a friend from Virginia to explain to us the difference between a Republican and a Democrat: his answer was that every self-respecting man was a Democrat; on the other hand, two friends of ours from New York spoke of the Democrats in terms too forcible for repetition. Here we are busy with our own election and we could make a very shrewd prophecy as to the result. But as the result will be known before our prophecy can be published, it seems futile to have it set up in type. In the United States it seems that there are three candidates for the Presidency, and that unless the favourite comes out well at the top of the poll, another man who is not a candidate at all will obtain the post. President Coolidge has not sent us a bound volume of his recent election addresses; but for this omission we should gladly have picked out the salient points from his abundant eloquence and given them amphoteric comments. We trust that the American chemists will make their voices and pens heard; we can assure them that if they come to this country after the voting is all over a warm welcome is always ready for them at the Chemical Industry Club.

* * *

Prof. W. E. S. T[illegible]ner has done much to improve the technology of glass-making. He has organised an important school of research, has published many papers and has collected and disseminated information about all the improvements and new discoveries in the subject of glass technology. Sheffield is the focus in which all this work is concentrated, and Prof. Turner's paper which he read there a few days ago contains much valuable matter. Those of us who are not engaged in the manufacture of glass and glass vessels do not find it easy—nor does it concern us—to estimate at their true value the Westlake machine, t[illegible]Hartford Empire feeder, or the Fourcault process. [illegible]t does interest us is that such devices are bein[illegible]hed and described by a man of science who ha[illegible]ted special attention to the subject and faces [illegible]oblems with the advantages of an acute mi[illegible]bundant knowledge. Many other industri[illegible]n a similar manner applying scientific kn[illegible]s and scientific methods for their own advant[illegible]he flax and linen industry is one which is r[illegible]us by the announcement in the daily pa[illegible]the appointment of a committee to study the growing of flax in this country. A few years ago we met an old man who remembered the time when the valley of the River Lea was brightened by many fields of flax. A hundred and twenty years ago, we think, in almost every county in England, and in almost every parish in those counties flax was grown. We have ourselves seen flax grown in Essex, principally by Scotsmen, who in that county have been remarkably enterprising and successful. But the glass industry and the flax industry are not the only ones profiting by modern research. The Fuel Industry is continually reminding us of its research department, and holding out hopes that very shortly the inhabitants of Sheffield and Stoke-on-Trent will be able to see the sun on other days than Sunday. Most of the other industries are also taking due advantage of modern science, and of all such sciences chemistry as we well know is the one which most quickly can be made use of by existing industries.

* * *

Some time ago the Fuel Research Board made the welcome announcement that it had been empowered to make tests at the public expense of plants for the low-temperature carbonisation of coal. The object of these tests is to furnish accurate technical data on the quality and quantity of yields; the throughput, working temperatures and general ease of working; and other general information on the plant under test. The Board points out very wisely that no attempt is made to pronounce on the commercial possibilities of any plant that is tested. Now we have the results of the first tests carried out, the particular plant investigated being a standard unit of the Parker plant for the low-temperature carbonisation of coal at the works of Low Temperature Carbonisation, Ltd., at Barnsley. The account of the tests, which has been published by the Department of Scientific and Industrial Research, makes interesting reading. The chief conclusions are that the throughput of 50 tons a day with 32 retorts accorded with that claimed; that the products were satisfactory in quantity and quality; and that certain defects in the plant which became evident during the trial could be remedied in future designs. The coke was of suitable size, and of good quality, and the yields of tar, gas, ammonia and gas were high. Such conclusions are encouraging, especially as the yields were slightly better than those obtained with a similar coal on an intermediate scale at the Fuel Research Station. The commercial possibilities of the plant, however, can only be judged after it has been worked continuously over a long period and after considering all costs, but the Report of the Fuel Research Board provides a basis on which at least an opinion of the future of low-temperature carbonisation can be founded. Whether the Parker process is to prove of general application, whether it is to be used only for the treatment of waste coal, whether its products will be as valuable as is claimed in some quarters, questions such as these have still to be answered. One can at least claim that there is much to be said for it from a scientific standpoint, but processes have to submit to the operation of economic laws, and these provide the final test of survival.

A DYNAMIC HYPOTHESIS OF CHEMICAL COMBINATION

By PROF. GILBERT T. MORGAN, F.R.S.

Hitherto chemists have favoured a static conception of electrons as an explanation of the facts of chemical constitution and of stereochemistry. But the physical evidence regarding atomic structure demands a dynamic conception. The object of this note is to suggest a general explanation of chemical combination based on the view that valency electrons are in a state of orbital motion.

Two limiting types of chemical valency are now generally recognised :—electrovalency, from which polar combination results, and non-polar valency leading to non-ionised substances. The former type, which is regarded as being due to the complete migration of an electron from one atomic system to another, may be exemplified by the union of sodium and chlorine to form the electrolyte, sodium chloride, wherein the valency electron of sodium has become part of the planetary system of chlorine. In a non-polar combination there is no complete migration of an electron, the combining elements share their valency electrons, so that this mode of combination is appropriately symbolised by the single and multiple bonds or linkings which appear so frequently in organic chemistry. However, the simplest form of non-polar combination, the single bond, is generally regarded as an affair of two electrons, each element concerned in the single linking sharing one electron with its consort. The double bond of organic chemistry is frequently, although not invariably, considered to involve the sharing of four electrons, two from each of the combining elements.

The simplest example of non-polar combination is the hydrogen molecule in which two electrons are shared between the two hydrogen atoms. Another simple example is furnished by dry hydrogen chloride in which the hydrogen electron is shared between the hydrogen and chlorine atoms.

According to Bohr's theory, the electrons of a single atom revolve round its nucleus in circular orbits in such a manner that no energy is radiated during the complete circuit of any single orbit; that is, each electron must be moving along a surface which is effectively an equipotential surface.

In the hydrogen molecule, the simplest binuclear system, the two electrons are now under the influence of both nuclei, with the result that their paths will no longer be circular, but in order that no energy may be radiated during a single revolution, each electron must still move along a path traced on an equipotential surface. In order that this condition may be maintained the possible orbits will all be included in the group of curves associated with the name of Cassini, the equation for these curves referred to bipolar co-ordinates being identical with the relationship expressing a constant potential. In the present case of hydrogen this is

$$\frac{e}{r} + \frac{e}{r'} = V \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots(1),$$

where V is the potential (a constant for each curve of the series), e the charge on each nucleus and r and r′ the distances from the nuclei of any point on the curve.

The curves obtained by taking various values of V are shown in Fig. 1, from which it will be seen that the family of curves is divided into two groups by the figure of eight curve, consisting of two lobes intersecting at O midway between the nuclei A and B. This bilobed curve, the well-known lemniscate of

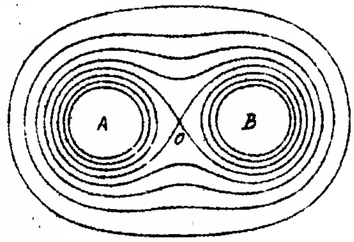

FIG. 1

Bernouilli, is a limiting curve which divides the family of Cassini curves into outer and inner series. The outer Cassini curves are continuous and encircle both nuclei. At first hour-glass in shape with a median constriction which gradually disappears as the value of the potential (V) diminishes, they approximate in the limit to elliptic and finally to circular orbits.

In non-polar combination, the path of a valency electron is an outer Cassini curve which includes both nuclei within its orbit. When two electrons are involved, as in the single bond or linking, they will move along two similar outer Cassini curves in planes inclined to one another in a manner approximating to the orbital planes of the two electrons in the helium atom.

This dynamic view of the single linking correlates the stability of saturated compounds with a similarity between their molecular structure and the atomic structure of the inert gas, helium. In methane, for instance, there is a fourfold helium arrangement of shared electrons. Round each hydrogen nucleus are revolving two electrons in outer Cassinian orbits simulating the behaviour of the stable arrangement obtaining within the helium atom. These four pairs of electrons will include the central carbon nucleus in their orbits, and the repulsion of the four positively charged hydrogen nuclei will result in a symmetrical tetrahedral arrangement which will persist in spite of the dynamic nature of the linkings.

Within the lobes of the lemniscate are the inner Cassini curves for higher values of the potential and each of these curves consists of two separated Cassinian ovals, one round each nucleus. This group of curves represents the condition of a valency electron in electrovalency; it is moving in an inner Cassinian oval round one of the nuclei. It may be remarked in passing that since any other electrons present in the two atomic systems are also under the joint influence of the two nuclei, their orbits will also be distorted from their original circular forms into

Cassinian ovals. And since this perturbation affects all the electrons in the binuclear system, it will be impossible after chemical combination has occurred to identify the electron which has either passed from one atom to the other, or which is being shared between them. This fundamental alteration in the orbits of all the electrons of the binuclear system finds a parallel in the profound and abrupt changes in physical and chemical properties which arise as a result of chemical combination. It also affords an explanation of the nascent state, of the equivalence of the four hydrogen atoms in the ammonium radical $[NH_4]$, and of the equivalence of oxygen and fluorine in Marignac's classical series, $K_2[TiF_6]$, $K_2[CbOF_5]$ and $K_2[WO_2F_4]$.

For simplicity this discussion is based on the example of two nuclei with equal charges, but the case of nuclei with different charges, although diverging from the symmetry of the Cassini curves, still preserves the fundamental principle of the movement

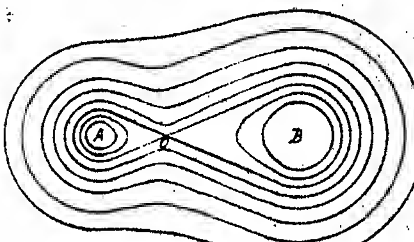

FIG. 2

of electrons along equipotential surfaces as given by the equation

$$\frac{Ne}{r} + \frac{N'e}{r'} = V \quad \ldots\ldots\ldots\ldots\ldots\ldots (2),$$

where Ne and N'e are the dissimilar charges on the two nuclei, the other terms having the same significance as in equation (1).

Fig. 2 represents the non-ionised molecule of dry hydrogen chloride; the two electrons implicated in non-polar linking rotate round both nuclei in Cassinian curves outside the modified lemniscate or figure of eight curve. When the hydrogen chloride is ionised by moisture the condition of the hydrogen electron is also shown in Fig. 2. If B is the chlorine nucleus, the hydrogen electron now revolves round this focus in an orbit which is an inner Cassinian oval comparable with those drawn within the larger lobe of the figure of eight (Fig. 2).

The foregoing figure also indicates in a similar manner the condition of the valency electron of sodium in sodium chloride. This electron is revolving in an inner Cassinian oval round the chlorine nucleus.

In more complicated examples where there are more than two nuclei, perturbations in the electronic orbits will arise owing to the mutual interactions of the va[illegible]clei, but in many instances this complication [illegible] diminished considerably by a symmetrical dis[illegible]on of these nuclei, as already indicated [illegible] of methane.

The double linking of organic chemistry corresponds with Langmuir's assumption of two co-valencies involving a sharing of four electrons between the two associated atoms. On the dynamic hypothesis now advocated this would result in the four shared electrons rotating round both nuclei in outer Cassini curves in four planes inclined approximately to each other at angles of 45°. The mutual repulsion of the electrons would, however, hinder this arrangement, and the alternative hypothesis of "mixed double bonds" advanced by Lowry (*Chem. Soc. Trans.*, 1923, **123**, 822) is, in certain instances, the more probable. In terms of the present hypothesis this alternative means that two of the four electrons rotate round only one of the nuclei in inner Cassinian ovals, whereas the other two maintain the non-polar junction by moving round both nuclei in outer Cassini curves in planes inclined to one another, as in the case of a single co-valency. This alternative agrees not only with Lowry's hypothesis of "mixed double bonds," but is also in accord with the conception of "bound ions" put forward independently by Pfeiffer in discussing the constitution of betaines (*Ber.*, 1922, **55**, 1762), and by Main Smith and myself in reference to the nature of the lakes of mordant dyes (*Chem. Soc. Trans.*, 1921, **119**, 705; 1922, **121**, 1957).

The triple linking offers similar difficulties. If three co-valencies are present, involving six shared electrons, these similarly charged particles would be moving round both nuclei along six outer Cassinian curves in planes inclined approximately at 30° to each other. The forces of repulsion thus called into play would militate considerably against the permanence of this arrangement. A more stable alternative would arise if only one pair of electrons were shared while one atom took over two electrons from the other. In this case the two shared electrons would move in outer Cassini curves round both nuclei and the two surrendered electrons would describe inner Cassinian ovals round the nucleus of the receptive atom. Such an arrangement may obtain in the acetylene molecule, and would lead to an interlacing of the electrons in the two carbon atoms which might account for the singular property possessed by the monosubstituted acetylenes, RC ⋮ CH, of yielding metallic derivatives.

As an inorganic example, the case of anhydrous chromic chloride may be cited. Insoluble and non-ionised in water, it represents a system with three non-polar linkings in which the shared electrons move in outer Cassini curves round the chromium nucleus and the chlorine nuclei. The addition of five molecular proportions of liquid ammonia first enables two of the three shared chromium electrons to be acquired by two chlorine planetary systems; two non-polar valencies become electrovalencies with two electrons derived from the chromium rotating in inner Cassinian ovals round the nuclei of two chlorine ions. The third chlorine atom is still retained in a non-polar bond until more ammonia frees it from this restraint, and the third valency electron from chromium then also describes an inner Cassinian oval round the nucleus of the third chlorine ion.

$$[CrCl_3] \rightarrow [CrCl, 5NH_3]Cl_2 \rightarrow [Cr6NH_3]Cl_3.$$

Although in the foregoing co-ordinated chromammine ions there are 21 and 24 associating nuclei respectively, these are arranged in regular order round the central chromium atom. The chromium nucleus is implicated octahedrally in six Cassinian electronic systems with six peripheral atoms consisting either of five nitrogens and one chlorine or of six nitrogens. These nitrogens are each implicated tetrahedrally in four Cassinian electronic systems, with four peripheral atoms consisting of three hydrogens and one chromium.

Although these assumed molecular arrangements are based on a conception of moving electrons, they have sufficient permanence to account for the facts of structural and steric isomerism. The persistence of these structures will result from :—

(1) The rigidity of rapid motion due to the swiftly revolving electrons in the interlocked multinuclear systems.
(2) The symmetrical distribution of the positively charged nuclei arising from their mutual repulsion.

In this way one arrives at the tetrahedral and octahedral structures which have so far been chiefly studied in stereochemistry. At the same time the dynamic conception allows to these systems the possibility of re-arrangement which is also demanded by the experimental evidence regarding racemisation, epimeric change and the Walden inversion. Under the stress of physical or chemical agents the spatial relationships of atoms in chemical compounds become modified owing to new perturbations in the orbital motions of the implicated electrons.

These electronic re-arrangements occur not only in non-polar compounds where combination is of the co-valency type, but also in the passage from the non-polar to the polar or electrolytic condition. In accordance with the dynamic hypothesis now put forward this chemical change is associated with the passage of valency electrons from outer to inner Cassinian orbits.

The fatty acids of the acetic series furnish a notable example.

$$\left[RC\begin{matrix} \diagup O \\ \diagdown OH \end{matrix} \right] \rightleftarrows \left[R.CO_2 \right]H.$$

In the pseudo-acid condition (the non-polar compound) the electron of hydroxylic hydrogen is moving in an outer Cassinian curve round both hydrogen and oxygen nuclei. In the true acid, the hydrogen electron has crossed the limiting zone of the modified lemniscate (Fig. 2), and is now moving in an inner Cassinian round an oxygen nucleus only.

Another case which illustrates the close proximity of electronic orbits to the critical lemniscate zone is seen in the behaviour of roseocobaltammine. In the chloride, three electrons from cobalt are moving in inner Cassinian curves round three chlorine ions respectively. Treatment with alkali produces an unstable triacidic base, in which these three electrons still revolve exclusively round hydroxylic oxygen, but this compound changes spontaneously into the hydroxopentamminocobaltic dihydroxide, in which only two of the three electrons persist in the inner Cassinian orbits while the third now revolves in an outer Cassinian orbit involving both cobalt and oxygen, this electron having passed from one side of the critical lemniscate zone to the other, an alteration brought about by changes in the dielectric character of the medium in which the reactive compound is placed. This medium may act catalytically, or, as is more usually the case in ionic changes, it may combine chemically with the dissociating compound.

$$\underset{\text{stable roseo salt}}{[5NH_3Co,H_2O]Cl_3} \rightarrow \underset{\text{unstable tri-acidic base}}{[5NH_3Co,H_2O](OH)_3} \rightarrow \underset{\text{stable diacidic base}}{[5NH_3Co.OH](OH)_2}$$

Many other relevant instances might be adduced but sufficient examples have been given to show how the conception of dynamic electrons in multinuclear systems may be used in explaining the facts of polar and non-polar combination, ionisation, tautomeric change and the characteristic properties of the principal types of inorganic and organic isomerism.

To those interested in the conception of dynamic electrons the following mathematical references may be useful :—

METALLURGICAL AND MINING NOTES FROM CANADA

A very rich strike of silver-lead ore has been made on Galena Hill, Keno City, Yukon Territory. The samples assay 700 oz. silver to the t. and 70 per cent. of lead.

The total output of salt, in 1923, amounted to 206,985 t., valued at $1,713,516.

The production of arsenic, calculated as As_2O_3, in 1923, was 3667·1 t., valued at $883,771.

The gold produced during the past year was 1,243,341, fine oz., valued at $25,702,139.

A shipment of 1000 t. of arsenical concentrates, from the gold-dumps of Nova Scotia, has been made to England.

The production of crude petroleum in Canada in 1923 was 170,169 barrels, valued at $522,018, as compared with 179,068 barrels, valued at $611,176, in the previous year, a decline of approximately 9000 barrels.

During the year ending June 20, 1924, the Laurentide Co. Ltd. made a net profit of $2,084,524, equal to 7·2 per cent. on the capital stock (6·2 per cent. in 1923); the working capital is $6,892,142. The amount allowed for depreciation for the past year was double that of the previous year.

A vein of rich silver ore, six feet in width, has been discovered near Fort William, Ontario.

OUR EMBASSY TO AMSTERDAM

By ONLOOKER

Our Dutch colleagues have done well to keep green the memory of their distinguished countryman, van't Hoff, by openly celebrating the Jubilee of the conception upon which the modern doctrine of stereoisomerism is based, published independently by Le Bel in France and van't Hoff in Amsterdam, in the latter part of 1874. Van't Hoff, it may be remembered, was brought up on a strange diet of Burton's *Anatomy of Melancholy*, Byron, Burns and Buckle; yet his contribution was so made and so simple that it almost forthwith gave solidity to chemists' speculations as to the character of optically active compounds in particular, and it has prevailed up to the present day, a vast amount of solid work being traceable to the influence it has had. At the public meeting, held on Saturday last, October 25, in the Aula of the Amsterdam University, the foreign visitors were first welcomed by a representative of the Netherlands Chemical Society; addresses were then delivered by Profs. Cohen and Walden. Prof. Cohen's speech was an eloquent appreciation of the two men, the section devoted to Le Bel being particularly happy in its allusions. The address is to be reproduced in *Chemisch Weekblad*. Beginning with a Shakespearian quotation:—

> "And, as imagination bodies forth
> The forms of things unknown, the (chemist's) pen
> Turns them to shape and gives to airy nothing
> A local habitation and a name"—

he asked his audience to imagine themselves in Piccadilly, London, on November 30, 1893, at the Royal Society, when Lord Kelvin presented the Davy medals, jointly awarded to J. A. Le Bel and J. H. van't Hoff.

Prof. Walden appears to have prepared a complete account of the development of Stereochemistry up to the present day, but could only summarise his conclusions. The address naturally suffered in consequence, and was less suited than Prof. Cohen's to a general audience, though it will doubtless be found to be invaluable when published.

A reception preceded the meeting, and tea followed it. Unfortunately, Le Bel could not be present. The French Chemical Society was represented by Mons. Delépine, our Chemical Society by Profs. Armstrong and Lowry, whilst Mr. Woolcock Box'd and Cox'd the parts of President of the Society of Chemical Industry and that of representative of the A.B.C.M. An American wandering in Europe had been captured to appear on behalf of the American Chemical Society. Prof. Walden was the delegate of the German Chemi[illegible] Society, and also appeared for the Russian So[illegible]; it may be mentioned that he is now Profe[illegible] Rostock; he was formerly in Riga.

In the [illegible]uct was given at the *Hôtel de l'E[illegible]* [illegible] of about 35, including the E[illegible]ador. Prof. Cohen was in the [illegible] was clear that his was the active organising [illegible] behind the celebration. The menu included [illegible]propriate lubricants):—Consommé Rumford, Turbotin Fischer, Pièce de Bœuf Liebig, Poulet en Casserole Pasteur, Bombe Berthelot. To enlighten the Saintsburys, we may say that Moët and Chandon's *White Star* was served both with the Hors D'Œuvre and the Poulet—not with the Bombe. The courses were seven, but the speeches—heavier than the courses—twice that number, taken at intervals throughout the meal. All were good and full of point. The astounding proficiency of the Dutch as linguists was very noticeable, especially in the Chairman, to whom English, Dutch, French and German seem to be but one language. He is an inveterate Byronist.

The celebration undoubtedly was very successsful. A friendly party of men, understanding one another, united to give pious effect to the feeling of gratitude which all who can appreciate the great gift our science has received from the two men in whose honour we were assembled.

Mr. Woolcock, it may be said, played the part of Pooh Bah to perfection. In his presidential capacity he was the Lord High Chancellor, advising that due economy must be observed. As (private) Secretary to the Alphabet he was always prepared "to do it well." Fate, however, was too much for him. As it is believed on the Continent that all Englishmen not in the War were stricken with knighthood, a higher honour was accorded to him, and even his hotel bill was made out to *Professor* Woolcock: the terms of the bill were in no way in accordance with the title; but there it is and must remain upon him in future. He deserves it, if only because of the able way in which, during dinner, he preached the doctrine of the inseparable state of chemical science and industry. There is no doubt that our English full recognition of the significance of the occasion was appreciated. On the other hand, it is clear that such exchanges of courtesy are of great value. These meetings, however, ever serve to remind us only too forcibly of our linguistic deficiencies.

Several of the party were privileged to attend the monthly meeting of the Dutch Academy on the Saturday morning. The Academy is limited to fifty members. A simple lunch is provided at 12-1, after which the formal meeting is held.

INDUSTRIAL FILTRATION

In the recent article on Industrial Filtration the speed of the Vickeen Separator made by the British Separators, Ltd., was given as 60 r.p.m. This number refers to the type of machine of which the actual speed is 7000 r.p.m. At this speed it is capable of purifying 200 gall. per hour of transformer oil at 50° C; the output given in the article relates to a test in which the oil flow was adjusted to the figure stated. For further information on these interesting machines, reference should be made to the catalogue (B.10) describing in detail the Vickeen Separators made by British Separators, Ltd. It should also be mentioned that the Gee Centrifugal is handled by the Centrifugal Separators, Ltd., not by British Separators, Ltd.

THE TRAINING OF CHEMISTS IN BACTERIOLOGY. II

By Dr. DAVID ELLIS

In a previous article* it was shown that the chemist who is desirous of using the microscope as a supplementary aid to his general work must approach the problem with a certain amount of care. Let him not imagine that all he has to do is to procure a microscope; and that the only thing he has to learn to do is to be able to make a focussing adjustment with the lens of the microscope. The lesson must be learnt that sensation is not perception. A better illustration for my purpose could not be adduced than the well-known fact that the dog staring at the portrait of his master in oils perceives nothing more than a mixture of various coloured smells which are not good to eat. The brute mind cannot ascend to the perception of his master's likeness in oils, although it cannot be doubted that his senses are equal, if not superior, to those of the human. This is, of course, an extreme case, but in a smaller degree, the same difference is manifest between the trained and the untrained microscopist. Any teacher whose business it is to train others in the use of the microscope will endorse the statement that there is an extraordinary difference in the perceptive powers of different people when they 'keek' through the microscope. The difference, of course, is a difference in the *perceptive* powers, and a well-developed power of observation is the result of the training which has been undergone by a naturally keen mind. This power cannot be brought into being by the mere act of buying a microscope and learning how to focus, no more than a joiner is made by buying a saw.

If we then accept the fact that a training in the power of observation is necessary, we must next enquire whether it is worth while for a chemist who has so many other things to train for. This is a question which the chemist himself must decide after a consideration of the kind of work which he will be called upon later to perform. But it must surely be a poor kind of chemist that can complete his life's work without feeling the necessity of examining the products of his reactions with other than the macroscopic methods. It seems to the writer that the research chemist must be prepared at any moment to supplement the ordinary methods of examining results, by the infinitely more delicate methods which are at his disposal when he has a microscope at hand, and knows how to work it. For example, sometimes in the *Journal* of the Chemical Society a substance is vaguely described as being in the form of prisms under the microscope. All prisms are not alike, they differ in length, breadth and thickness, some are complete, others are so incomplete that their form has to be built up by the examination of many fragments. A more familiar instance is the identification of sugars by osazones and for this identification the microscope is necessary. In certain kinds of work the microscope is indispensable as, for example, when the identification of certain alkaloids is accomplished by the microscopical examination of their salts. Many other examples might be adduced showing how comparatively simple work with the microscope can make a large difference to the accuracy of the final result. It is, however, when we come to the adulteration of foodstuffs, and particularly when we deal with the examination of bacteria, yeasts and moulds, that a comparatively long training is necessary before the student can be regarded as an adept at the work. The work in these branches is essentially more an application of biology, rather than of chemistry; but in spite of this fact the work of identification can be carried on for the most part without special knowledge of biology.

The course in microscopy that is suggested for chemists is one that begins by making drawings of gross objects which are observed under the low powers of the microscope. The inevitable sting of a bee that is used by most beginners of microscopy, may be employed to train the 'prentice eye; but better would be a section of a plant stem, or a large diatom or any one of the hundreds of objects that may be bought, mounted on slides, in which a thin slice of an object that is about a millimetre in width, and which is thin enough to be transparent, is embedded in a transparent material. The novice may not know what the object is, but for the present purpose this is immaterial. So long as he is able to show by means of a drawing that he apprehends the true structure of that which he is drawing, it does not matter much whether the drawing be good or indifferent.

When this stage has been satisfactorily passed, the student may now tackle something more difficult. A good example of the second stage is supplied by the pollen grains of flowers. A better one, and one in which the material is more accessible, is the examination of the membranous cuticles of leaves. A thin transparent sheet, about a millimetre across can easily be torn from the upper layers of a leaf and examined mounted in water. This exercise has its utilitarian aspect for, in the examination of vegetable powders, the microscopical appearance of the leaf-epidermis is a great help in the work of identification. At this stage exercises should be undertaken in the preparation of hard substances like seeds, barks, and roots for examination under the microscope. When fragments are taken from different parts of an organic structure and rendered transparent by appropriate means, and when these are examined with minute care, the best of all exercises is supplied to the mind, which is thus enabled to build up satisfactory perceptions from the sensory data. A supply of vegetable powders can be obtained from any pharmacist. These may be examined in detail and drawings made from the fragments under observation. It does not matter that the chemist cannot build up the whole organic structure from the fragments; he gains experience in the sharpness of vision that results as much from the co-ordination of his perceptions as from his optic sensations.

A fresh line of work of a similar character might then be taken by an investigation of the points which distinguish the different starches; or the crystals which form when beef-fat or lard is treated with ether may be made the basis of a useful exercise. These

*Chem. & Ind, June 6, 1924

are only suggestions of possible examples in which a combination is offered of educative, and at the same time useful, exercises, all of them trending towards a point when sufficient advance will have been made to enable the student to profit by the study of micro-organisms. At first only comparatively large organisms like yeast or some of the larger moulds should be put under observation; after which, exercises should be given to show the structure of the bacteria. This should be the culminating point, and before the study of bacteria is reached a number of organisms taken from the animal as well as from the plant world should be examined. For example, let the chemist by observation put on paper his impressions of the appearance of a volvox, a desmid, an amœba or any other of the micro-organisms that are found when an organic fluid is allowed to putrefy. Then finally let the one-twelfth oil immersion lens be brought out, and the study of the forms of the different kinds of bacteria undertaken. The steps leading up to such a culmination need not all take the same direction, except that all must work upwards. The chief feature should be a gradual ascension, the route depending on the facilities at the teacher's disposal. This is surely better than standing on the beach and trying to reach the summit of the cliff at one leap, as is done in practically every case where the chemist is put to study bacteriology as a part of his course for the degree in applied chemistry.

LIFE AND WORK OF DR. LUDWIG MOND

The inaugural lecture under a scheme established in accordance with the provisions of the will of the late Mrs. Mond, in memory of her husband, the late Dr. Ludwig Mond, was delivered on October 20, by Prof. H. B. Dixon, F.R.S., at the Manchester University. The scheme provides for the delivery, in alternate years, of lectures on pure science, applied science, and some other subjects.

The Vice-Chancellor of the University (Sir Henry Miers) in calling upon Prof. Dixon to deliver his lecture, said that, owing to the beneficence of the late Mrs. Mond, they were enabled to bring distinguished scientists to lecture, not only to the students at the University, but also to the public at large. The late Dr. Ludwig Mond was representative of both pure and applied chemistry, and he was pleased to find they were honoured by the presence of Dr. Robert Mond, the eldest son of a most distinguished father.

Prof. Dixon, in delivering his lecture on the "Life and Work of Dr. Ludwig Mond," referred to the address given by Dr. Mond at the opening of the first laboratory in Great Britain designed for the special study of organic chemistry—the laboratory built in that college as a memorial to Prof. Schorlemmer. Dr. Mond said: "Our progress is measured by the increase of our knowledge, which alone enhances our power over the forces of nature and enables us to turn them to the uses of man. Any advance in pure science is very soon followed by advances in our industries. The immense development in the practical application of electricity, for instance, which we have witnessed of recent years, we owe far more to Faraday's scientific work than to all the numberless inventors who have followed up his various discoveries and turned them to practical use." Those words were spoken in that very room nearly thirty years ago by the greatest technologist of the time. Those words were in no sense a conventional tribute paid to pure science from a successful industrialist; on the contrary, they embodied the working creed of a man who knew from experience how progress in industry could alone be achieved. The life of Dr. Ludwig Mond was modelled on this belief, his industries were founded and built on scientific study, and by his generosity he repaid what he felt to be his debt to science by creating and aiding opportunities for scientific research. In Manchester, they were grateful to him for the assistance he gave in the study of organic chemistry, and of electro-chemistry. In the fulness of time, there came also the splendid gift to the nation of the "Davy-Faraday" laboratory.

Prof. Dixon then dealt with the educational period of Dr. Mond at Cassel, Marburg, and Heidelberg, his friendship with Bunsen and Solvay and his connexion with the improvement of the Le Blanc process for the manufacture of artificial soda. The early struggles of the late Sir John Brunner and Dr. Mond in the successful foundation of the great works at Winnington were fully described. An estate of 130 acres was purchased from Lord Stanley. The old hall belonging to it was restored and divided as a residence between them. In 1874, they produced their first soda. Some conception of their initial difficulties with their plant could be gleaned from Sir John Brunner's words, when he said, "Everything that could break down did break down, and everything that could burst did burst." For some time Mond slept on a platform over the engine. He was constantly strengthening and improving the apparatus, while a no less arduous labour was that of training the workmen. Following the success of the Winnington undertaking, the most inventive years of his life began. He stabilised the ammonia process, designed the Mond gas-plant for providing smokeless fuel and power, and dealt with the loss of chlorine in the Solway process, and did much other noteworthy work. The lecturer then referred to the invaluable services rendered by the firm to the nation during the war-period, than which there could be no greater monument to the genius of the late Dr. Mond. As an employer, he was known to be just, considerate and generous to his workmen.

Prof. Dixon also dealt with that period of Dr. Mond's life which was passed in Rome, and further stated that he never sought for honours, but he gratefully accepted the distinctions offered him by universities and scientific societies. He acted as foreign secretary to the Society of Chemical Industry from its foundation until he became its President, and was President of Section B of the British Association. Again, he was long a fellow of the Chemical Society, but declined to allow himself to be nominated as President upon the ground of ill-health. In 1891, he was elected a Fellow of the Royal Society, and served upon its Council, whilst the International Congress of Applied Chemistry held in London in the

summer of 1891 he was host to the foreign chemists attending the Conference. This was the last public function he attended. His fine constitution yielded to the insistent calls he made on its strength—the mind tired out the body. In the autumn he began to sink, he passed away at the age of seventy-one, and was interred in the mausoleum he had erected at Finchley.

In conclusion, Prof. Dixon said it was not his privilege to know the late Mrs. Mond until more than twenty years after her marriage, but no one could meet her then without being struck by the alertness of her intelligence, the charm of her manner, and the quick response of her sympathy.

The vote of thanks to Prof. Dixon for the lecture moved by Dr. Robert Mond.

THE MAKING OF A COMPLEAT CHYMIST *

By HENRY E. ARMSTRONG

My text is taken from the Prologue of "King nry V":—

> For 'tis your thoughts that now must deck our kings,
> Carrying them here and there; jumping o'er times,
> Turning the accomplishments of many years
> Into an hour-glass—."

nd I,

> "prologue-like, your humble patience pray,
> Gently to hear, kindly to judge (my) play."

I was present at the opening of Mason's College 1880 and heard Huxley give his address. In ong waiting for my turn, I have learnt not a little. Huxley was the noted prize-fighter of his time but am a man of peace—though I confess to resembling im in hating parsons and all their tortuous ways subordinating freedom of thought. He spoke to e public. I am invited to address a Students' ociety. I am speaking only to a section of your University. I would appeal, however, to the wide ircle of all those who are concerned with *The earch after Truth.* I see no reason why a Barrie r a Kipling should be permitted to deliver his essage to the public through, may I say, rough oung Scots and a Chemist, talking to a body of mild Midland students, should not equally speak out to all whom his thoughts may concern. In the world of to-day *Chemistry* is at least the equal of *Courage* in importance. Indeed we live and have our being wholly and solely through the constant, regulated occurrence of chemical interchanges without which courage could not be, of which, however, carce anything worth speaking of is understood, s yet, though it is becoming more and more clear o us that, *au fond,* we are but chemical mechanisms, *pace* Dean Inge and Prof. McBride. We are such stuff as dreams are made of—interpreted by the structural chemist, this means that stuff and dreams are reciprocally related: the one cannot be without the other; *Gheist* is a function, not an entity with survival value—as the Dean claims.

* An address delivered to the University of Birmingham Chemical Society, October 20, 1924.

The chemist may be no word-slinger but he may be at least the equal of the literary man and of the man of affairs in his knowledge of matters of public importance. The world has too long bowed down before mere words—it now calls for calculated action under the direction of students of affairs who are willing to use, if not experienced in the use of, scientific method—*the* method of the future, *the only method* by which we can hope to have and hold a future. I would ask you to note my use of the term Student, not Man, of affairs—the latter being too often but a man who does things without knowing why or counting the cost and, because he sometimes succeeds, is not seen through.

Huxley's topic was Science and Culture. You may read the address in his Collected Essays, Vol. III. His thesis was that, although the culture of former periods may have been purely literary, to-day it must be based, to a great extent, mainly upon Natural Science.

My subject—The Making of a Compleat Chymist—is similar to Huxley's. I have to ask to what extent the movement has been a success which he was advocating. I have some right to speak, as I took service in the Technical Educational Movement in 1879 and have been connected with the foundation of two technical colleges, the Finsbury Technical College and the Central Technical College of the City and Guilds of London Institute. May I add that I have lived long enough to have lost, if not all sense of modesty, all sense of reverence for authority: so that I can speak out perhaps with some of the courage which Barrie advocated, which unfortunately is greatly at a discount in these subservient days. It is very necessary, if we are to hold our Empire, nay, a place at all in the world, that some of us should state our convictions.

Izaak Walton's *Compleat Angler* is a noted classic, full of literary charm as well as of the technical lore of its time. No *Compleat Chymist* has yet been written but the competent writer, if ever he be found, will have endless material at his disposal and should be able to make his story thrill with interest. Go to Wondrous Wembley and ask the meaning of the various exhibits: chemistry is behind most of them—those in the Palace of Engineering would be impossible without it; indeed, the engineer is little more than a tool of the chemist, practising a few well-proved mechanical turns upon materials handed out to him through the chemical laboratory: it's like *Ubique*, in Kipling's poem, which lacks a verse for chemistry. Had the poet been cultured up to Huxley's point, he would certainly have introduced one:—

> It serves 'Orse, Field an' Garrison as motto for a crest,
> An' when you've found out all it means I'll tell you 'alf the rest.
>
> . . . .
>
> There's nothin' this side 'Eaven or 'Ell Ubique (No Chemistry) doesn't mean.

It is the science of the materials composing the universe and of their interactions, including vital phenomena; it is the science of character. Fighting is now impossible without it and it is paramount in

peace. Yet, who cares? Your mission will be to make people care and you must qualify to this end.

The chemist may not greatly love the society of the clergy or connect himself with Episcopal families and have a natural taste for a Bishop—as the good Izaak is said to have done, according to Andrew Lang. Still, he has a duty towards Bishops—if possible, to make them persons who *can see, real feeders* of their flocks, with some respect for the beauty and truths of Nature. Bishops, in my experience—I have grown up with and known a good many—are simple, apparently harmless, people; they succeed, however, in doing much harm through their sublime disregard of all modern effort to arrive at the truth and an understanding of the world—your Bishop-Designate perhaps excepted—due partly to the fact that they have been at public schools and partly to the narrow ideals of education which prevail in their profession but chiefly perhaps to their special mentality—the duality, if not plurality, of their nature. I would here challenge Dean Inge's statement (in his essay on Roman Catholic Modernism), that there cannot be two faculties in the human mind working independently of each other. It is only necessary, in Birmingham, to mention the name of my gifted friend, Sir Oliver Lodge. Has not R. L. Stevenson, too, given us Dr. Jekyll and Mr. Hyde? Did he not mean us to accept them as types?

Now, gentlemen, if one of your future functions be the reform of Bishops, you must live up to Huxley's programme of 1880. You must first learn to express yourselves clearly in terms which Bishops can understand—without putting too great a strain upon their understanding. At present, the cloth of science speaks only in terms of conundrums "which no fellow can understand." Huxley was almost the last of the clan to use clear and concise language and could express himself in incisive terms which carried conviction even to the uninstructed. I recommend you all to study his "Life and Letters" and especially his "Collected Essays." Buy these latter, if you can. The "Jargonauts" now reign and if dropped from aeroplanes upon Babel would snow Babylon under. To keep our science from suffering the fate of that city and its tower we must refine our language and at least bring it down to the level of our own understanding. Charity begins at home. I would therefore recommend, as an exercise in construing a modern language, the translation into nursery English of Part XX. of *Researches on Residual Affinity and Co-ordination*, in the current number of the *Journal of the Chemical Society*. I read there of "chelate groups" and wonder what they are: mayhap something which only a *vorpal blade* would cut, to be found in *mimsy borogoves*; my childish mind also turns to the Zoo and the *Chetah* and I ask if perhaps Chelates are its near relatives: no amount of *uffish thought* I can give to it leads me to understand the term. This is but an example of a present-day perversity which, with the best intentions, our professors are foisting upon us. As to this matter of language, you know it is often said by Bishops, "As it was in the beginning, is now," &c.; in fact, you are what you are largely in virtue of what you were made to be at school. Your language may have been refined and acquired emphasis but your outlook in language will be mainly that put upon you at school. As man is nothing without speech, it stands to reason that speech should be his first study; but speech is to be learnt through use. Our English schools have yet to give proper training in the use of speech. I shall be told it is given and is best given through classics—in translating; but this is to postpone the training to a late period and not to give it at all to most. My view is that it should be given from the nursery onwards, through the translation of everyday action into thought—through the description of things done. The instruction can then begin as soon as the child can write. I know what can be done, because I have done it and seen it done with a considerable number of young children in schools. Parenthetically, may I suggest that Lewis Carroll wrote in anticipation of the Jargonauts—to prepare children for the pernicious language of science.

Until scientific method be really taught in schools, I believe there will be no proper training in the art of expression. Experimental work is properly done only when it is properly described; in it lies infinite opportunity to develop the powers of expression. The worker has something to write about.

As to yourselves, what practice have you in the art of writing? Very little, I fear. Writing isn't chemistry, you may say. Yes, it is; the fact that complaint is so frequently made of our writing, of our inability to express ourselves clearly and concisely, is proof of the need of such training. To my knowledge, there has been a continuous quarrel, during the past fifty years, between the Chemical Society and its contributors. The man who devised the three-column system of *Experiment, Observation, Inference*, deserves utmost execration; no more grievous misservice could have been done to our science. It is impossible to overrate the value of a well-ordered, readable note-book; it is an unfailing mirror of the worker's mind.

You must learn also to read—that is an even more valuable art. Hear what Stevenson says in his *Essays in the Art of Writing*. (Chatto and Windus. 1920):—

"The gift of reading is not very common nor very generally understood. It consists, first of all, in a vast intellectual endowment—a free grace, I find I must call it—by which a man rises to understand that he is not punctually right, nor those from whom he differs absolutely wrong. He may hold dogmas; he may hold them passionately; and he may know that others hold them but coldly or hold them differently or hold them not at all. Well, if he has the gift of reading, these others will be full of meat for him. They will see the other side of propositions and the other side of virtues. He need not change his dogma for that but he may change his reading of that dogma and he must supplement and correct his deductions from it. A human truth, which is always very much a lie, hides as much of life as it displays. It is men who hold another truth or, as it seems to us, perhaps a dangerous lie, who can extend our restricted field of knowledge and rouse our drowsy consciences. Something that seems quite new or that seems insolently false and very dangerous is the test of the reader. If he tries to see what it means, what truth excuses it, he has the gift and let him read. If he is merely hurt or offended or exclaims upon his author's folly, he had better take to the daily papers; he will never be a reader.

Not all men can read all books; it is only in a chosen few hat any man will find his appointed food; and the fittest essons are the most palatable and make themselves welcome o the mind. A writer learns this early and it is his chief upport; he goes on unafraid, laying down the law; and e is sure at heart that most of what he says is demonstrably alse and much of a mingled strain and some hurtful and very ttle good for service; but he is sure besides that when his vords fall into the hands of any genuine reader, they will be veighed and winnowed and only that which suits will be ssimilated; and when they fall into the hands of one who annot intelligently read, they come there quite silent and narticulate, falling upon deaf ears and his secret is kept as if e had not written."

If you can digest this advice you will have learnt ow to read.

I have said enough about words—let me now ass to works. When Huxley spoke it was on ehalf of the Mason College—that is long since lossomed into the Birmingham University. Other wns have done likewise. Universities now abound our country. To what extent is Chemistry the tter? How many students attending our Univeries, other than Cambridge and Oxford, have any er than professional ends in view? To what nt are the Universities meeting public needs, se of the general public and of the schools— ltural as distinct from technical needs? The swer is unsatisfactory. Professor Smithells, who always a charitable critic, who had a great oppornity of judging, during the war, in connexion th the gas-mask drill, only in January this year de the statement, in his Presidential Address to e Science Masters' Association, that:—

eneration of science teaching has produced a very disapntingly small dissemination of scientific knowledge of an ilable kind among our people. In a school in which three lions of men from all classes of society were dealt with, whom a little real knowledge of elementary science meant difference between life and death, the rudiments of such owledge were not to be found in one man among a hundred. science, so far, has edified and instructed far less than reasonably to be expected from a movement that has n carried out for so long and with such vigour.

This is a serious charge against our Universities general. The teachers are of their training and y call the pace through their entrance and other minations. In our well meant attempt to prove our educational system, we have jumped m the frying pan into the fire. Formerly, we e dominated by ecclesiasticism: now we are trolled by clericism: the teacher is neither free teach what he will nor the student to learn what may; both are confined to what will pay in examinations. *Lern* and *Lehrfreiheit* are gone. e system is the greatest curse our civilisation has ed down upon itself and the chief check to our llectual advance. I am one of the few who w up before it came into existence and so am e to appraise its consequences perhaps better n those who have never known freedom. Univeres are rapidly becoming a most potent means of reotyping and sterilising thought—they are acting s intellectual trades unions, if a trade union can be intellectual. An examination system such as we are now building up through the agency of dull conformists must, in the end, destroy freedom of thought: it has so done already.

The average value of the chemist is steadily being lowered, at the present day, through the introduction into the profession of a large class of drones who may have the acquisitive power to pass an examination but are without real intellectual ability: the burden laid upon such men—unfortunately there are many women among them—is far beyond that they can carry. The position is made worse by the attempt to standardise. Man must ever seek to mould himself after one image—his tendency is to resent all expression of individuality.

To argue the case now is impossible: I can but give my considered opinion—for what it is worth.

In the year that he came here Huxley also delivered an address at the Working Men's College on *The Method of Zadig*. I advise you all to study this. To quote his son, the text of this is—

Voltaire's story of the philosopher at the Oriental court who, by taking note of trivial indications, obtains a perilous knowledge of things which his neighbours ascribe either to thievery or magic. This introduces a discourse on the identity of the methods of science and of the judgments of common life, a fact which, twenty-six years before, he had briefly stated in the words, "Science is nothing but trained and organised common sense."

Common sense may pass as a conventional term, though, of course, what is meant is an uncommon sense. Science is a failure in our schools and Universities simply because the method of Zadig remains unpractised, both in public and private. You cannot teach for set examinations to a syllabus —always a mind-limiting compromise and behind the times—and also teach Zadig.

The method behind Science, *scientific method*, used more or less unconsciously by its devotees and all pioneers, is not a systematised, acknowledged method. The Universities do not seek to teach it; small wonder, then, if the teachers who wander into the schools in no way seek to inculcate its practice.

The Universities should be schools for the masses, in the sense that they should provide competent suitable teachers—they do not. They are all of them simply professional schools, not seats of liberal education in the first place.

It is a standing reproach to the great schools at Oxford and Cambridge especially that they make no attempt to train and Zadig-ise the plain man; they care only for the Honours student who aims at being a professional of some kind. Oxford perhaps is the lesser sinner but that probably is because it attempts least—its tendency being to bury its head mainly in the sands of the past and in words; the experimental sense is scarce developed there. It is a long time since Voltaire wrote; it is a long time since Huxley preached; we say that it is a long lane that has no turning—yet 44 years is too long a period to dwell in the wilderness, for the prophet to await the chance of a collision at the cross-roads. Huxley, in fact, was wrong in saying that science was nothing but trained and organised common sense—if he intended the implication to go with this statement that the sense was in any way common and educable. The scientific faculty seems, indeed, to be very rare.

I fear Huxley's dream has not been justified; I doubt if it ever will be. The progress of scientific discovery has been marvellous—but that is the work of the few. The spread of scientific method among the people amounts to very little. The Press has less concern with us than it had in Huxley's day: only the sensational meets with notice; strangely enough we meet with most sympathy from the most conservative of our newspapers. In the art of public thinking we are much as we were generations ago. Science can help us eventually very little, unless it help us to think straight. A political impasse like the present would be impossible, politicians would not resort to merely personal invective, were we governed by the rational exercise of thought—if we were not entirely conceited as to our individual judgments and oblivious of method, ignorant of the world's working. We in no way aim at a collective treatment of our problems.

I shall best bring my meaning home to you if I say *that you don't know what an experiment is*; that your pride of knowledge is such that you are intolerant of thought. Yours is the disease of *mental inertia*: read Faraday as to this state.

Our Universities are but at an embryonic stage of their scientific development. A vast body of fact is taught but the general principles of philosophy and scientific procedure are yet to be codified and made primary subjects of study—we are not yet arrived at the stage of making the teaching of logic a first charge upon the teacher, whatever his subject.

The *Compleat Chymist* is made only when the student can leave the University and say in Tommy's words:—

Peace is declared an' I return
  To 'Ackneystadt but not the same;
Things 'ave transpired which made me learn
  The size and meanin' of the game.
I did no more than others did,
  I don't know where the change began;
I started as a average kid,
  I finished *as a thinkin' man.*

Before my gappin' mouth could speak,
  I 'eard it in my comrade's tone;
I saw it on my neighbour's cheek,
  Before I felt it flush my own.
An' last it come to me—not pride,
  Nor yet conceit but on the 'ole,
(If such a term may be applied)
  The makin's of a bloomin' soul.

It's the bloomin' soul that counts—that may come with easy provocation to the elect. I have seen it come in a youngster who took to the game of experimental inquiry and, having solved his problem alone, by means of a few properly thought-out trials, at once wrote to tell me of his success: that he *had* slain the Jabberwock:—

O frabjous day! Callooh! Callay!
  He chortled in his joy.

He had actually *discovered* oxygen by himself. That [illegible] more than twenty-five years ago—the lesson [illegible] fruit, as he has ever since been strictly methodical [illegible] his work, far beyond the average.

(*To be continued*)

FORTHCOMING EVENTS

Nov. 1. NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS. Excursion Meeting at Horden Colliery. Train leaves Newcastle Central Station at 10 a.m.

Nov. 3. SOCIETY OF CHEMICAL INDUSTRY, *London Section*, at the Chemical Society's Rooms, Burlington House, Piccadilly, 8 p.m. "Experiments in Protection," by W. J. U. Woolcock, C.B.E. Members may dine at the Chemical Industry Club before the Meeting.

Nov. 3. ROYAL INSTITUTION, Albemarle Street, Piccadilly, W., at 5 p.m. General Meeting.

Nov. 3. INSTITUTION OF ELECTRICAL ENGINEERS, The Public Library, Alexandra Road, Swansea, at 6 p.m. Discussion on "Power Factor Improvement" opened by R. G. Isaacs.

Nov. 3. UNIVERSITY OF BIRMINGHAM CHEMICAL SOCIETY, Chemical Lecture Theatre, Edgbaston, Birmingham, at 5.30 p.m. "Application of Science to the Production of Gems," by J. R. Dolphin.

Nov. 3. INSTITUTION OF THE RUBBER INDUSTRY, Engineers' Club, Coventry Street, London, W., at 8 p.m. "Gutta Percha: Preparation and General Properties," by C. W. H. Howson.

Nov. 4. INSTITUTION OF PETROLEUM TECHNOLOGISTS, the House of the Royal Society of Arts, John Street, Adelphi, W.C. 2, at 5.30 p.m. "The Oilfields of Argentina," by C. M. Hunter.

Nov. 4. MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY, 36, George Street, Manchester, at 6.30 p.m. "The Phosphorescent Flame of Carbon Disulphide," by the President.

Nov. 4. INSTITUTE OF METALS, *North-East Coast Section*, Armstrong College, Newcastle-on-Tyne, at 7.30 p.m. "Structure of Metals in its Relation to Elastic Failure" (Part II), by W. E. W. Millington.

Nov. 4. INSTITUTE OF METALS, *Birmingham Section*, Chamber of Commerce, New Street, Birmingham, at 7 p.m. "Brazing," by A. R. Page.

Nov. 4. WEST YORKSHIRE METALLURGICAL SOCIETY, The George Hotel, Huddersfield, at 7.30 p.m. Discussion on "Influence of Casting Temperature on the Physical Properties of Non-Ferrous Alloys."

Nov. 4. MANCHESTER UNIVERSITY SCIENCE FEDERATION, Chemistry Lecture Theatre, Manchester, at 5 p.m. "Some New Problems in Therapeutics," by Dr. H. H. Dale.

Nov. 4. INSTITUTION OF CIVIL ENGINEERS, Great George Street, London, S.W. 1, at 6 p.m. Address by the President, B. Mott, C.B.

Nov. 5. INSTITUTION OF CHEMICAL ENGINEERS, University College, Gower Street, London, W.C. 1, at 8 p.m. "Water Gas Process," by Dr. M. W. Travers. (This meeting is in place of the one proposed for November 12.)

Nov. 5. SOCIETY OF CHEMICAL INDUSTRY, *Nottingham Section*, University College, Nottingham, at 7.30 p.m. "The Testing of Bates in the Laboratory," by Dr. C. E. Pickard.

Nov. 5. INSTITUTION OF ELECTRICAL ENGINEERS, Savoy Place, Victoria Embankment, London, W.C. 2, at 6 p.m.

Nov. 5. INSTITUTION OF SANITARY ENGINEERS, Annual Dinner at the Holborn Restaurant, London, W.C. 1, at 7.30 p.m.

Nov. 5. SOCIETY OF PUBLIC ANALYSTS, The Chemical Society's Rooms, Burlington House, Piccadilly, W. 1, at 8 p.m. (1) "On Certain New Methods for the Estimation of Arsenic and its Occurrence in Fish and Urine," by H. E. Cox. (2) "The Estimation of Cadmium in Brass," by A. T. Etheridge. (3) "The 'Hoyberg' Method of Milk and Cream Testing," by N. C. Wright and J. Golding. (4) "An Apparatus for the Catalytic Dehydrogenation of Alcohols," by S. G. Willimott.

Nov. 6. SOCIETY OF DYERS AND COLOURISTS, *West Riding Section.* "Photography in Dyestuff Testing," by T. Thorne Baker.

Nov. 6. UNIVERSITY OF LONDON, St. Thomas's Hospital Medical School, Albert Embankment, London, S.E. 1, at 4.30 p.m. "Enzymes," by Prof. J. Mellanby.

Nov. 6. SOCIETY OF CHEMICAL INDUSTRY, *Bristol Section,* The University, Woodland Road, Bristol, at 7.30 p.m. "The Present Position of the Geber Problem," by E. J. Holmyard.

Nov. 6. INSTITUTION OF MECHANICAL ENGINEERS, *Glasgow and West of Scotland Section,* Royal Technical College, Glasgow, at 7.30 p.m. "Steels and their Selection," by Prof. J. H. Andrew.

Nov. 6. INSTITUTION OF MECHANICAL ENGINEERS, *North-Western Section,* Engineers' Club, Albert Square, Manchester, at 7 p.m. "The Missing Pressure in Gas-Engines," and "Heat Loss in Gas-Engines," by Prof. W. T. David.

Nov. 6. THE CHEMICAL SOCIETY, Burlington House, Piccadilly, W. 1, at 8 p.m. (1) "Investigations on the Dependence of Rotatory Power on Chemical Constitution. Part XXIV. Further Experiments on the Walden Inversion," by J. Kenyon, H. Phillips, and H. G. Turley. (2) "Studies of Valency. Part V. The Mechanism of the Walden Inversion," by T. M. Lowry. (3) "A Spectroscopic Study of the Luminescent Oxidation of Phosphorus," by H. J. Emeléus and W. E. Downey.

Nov. 6. FINSBURY TECHNICAL COLLEGE, *Streatfeild Memorial Lecture,* in the Chemical Theatre of the College, Leonard Street, City Road, London, E.C. 2, at 4 p.m. "The Chemist and the Fermentation Industries," by J. L. Baker.

Nov. 7. INSTITUTION OF MECHANICAL ENGINEERS, *Midland Section,* Chamber of Commerce, New Street, Birmingham, at 7.30 p.m. "Pulverised Coal," by K. C. Barrell.

Nov. 7. INSTITUTION OF MECHANICAL ENGINEERS, *The Thomas Hawksley Lecture* at the Institution, Storey's Gate, St. James's Park, London, S.W. 1, at 6 p.m. "The Trend of Development of Marine Propelling Machinery," by Engineer Vice-Admiral Sir G. G. Goodwin.

Nov. 7. UNIVERSITY OF LONDON, King's College, Strand, London, at 5.30 p.m. "The Ideal Aim of Physical Science," by Prof. E. W. Hobson.

Nov. 7. INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND, *Manchester Section,* Joint Meeting with the Manchester Sections of the Society of Chemical Industry, Society of Dyers and Colourists, and Literary and Philosophical Society, at Textile Institute, St. Mary's Parsonage, Manchester, at 7 p.m. "The Influence of Chemical Research on Medicine and Forensic Medicine," by Sir W. H. Willcox.

Nov. 7. SOCIETY OF PUBLIC ANALYSTS, Manchester Literary and Philosophical Society, 36, George Street, Manchester, at 3 p.m., to discuss the formation of a North of England Section.

SOCIETY OF CHEMICAL INDUSTRY

CHEMICAL INDUSTRY DINNER

The Autumn Dinner, which will be under the auspices of the Society of Chemical Industry and the Chemical Industry Club, will be held in the Edward VII Rooms of the Hotel Victoria, Northumberland Avenue, London, W.C. 2, on Friday, November 14, at 7 for 7.30 p.m., and will be presided over by Mr. W. J. U. Woolcock, C.B.E., President of the Society.

A circular letter with further particulars and a form of application for tickets has been sent out to the members.

SUSPENSION OF ENTRANCE FEE

As an inducement to chemists to become members, the Council has resolved that no entrance fee shall be paid by members joining the Society in 1925.

A form of application for membership was inserted at the end of this Section in the issue of the Journal for October 17, and it is hoped that it may be used to introduce a new member for next year.

ANNUAL REPORTS OF THE PROGRESS OF APPLIED CHEMISTRY

VOL. IX (1924)

This volume is in course of preparation, and an order form will be sent out in due course with the application for the annual subscription for 1925.

The list of subjects dealt with and the names of the authors is as follows:—

Plant and Machinery	S. G. M. Ure.
Fuel	J. W. Cobb and H. J. Hodsman.
Gas—Destructive Distillation—Tar Products	W. B. Davidson.
Mineral Oils	S. J. M. Auld.
Colouring Matters and Dyes	E. H. Rodd.
Fibres, Textiles, Cellulose, and Paper	S. H. Higgins.
Bleaching, Dyeing, Printing, and Finishing	A. J. Hall.
Acids, Alkalis, Salts, etc.	P. Parrish.
Glass	E. A. Coad-Pryor.
Ceramics, Building Materials, and Refractories	W. J. Rees.
Iron and Steel	C. O. Bannister.
Non-Ferrous Metals	C. A. Edwards.
Electro-Chemical and Electro-Metallurgical Industries	J. N. Pring.
Oils, Fats, and Waxes	H. M. Langton.
Paints, Pigments, Varnishes, and Resins	C. A. Klein.
Indiarubber	D. F. Twiss.
Leather and Glue	D. M. McCandlish.
Soils and Fertilisers	H. J. Page.
Sugars, Starches, and Gums	L. Eynon and J. H. Lane.
Fermentation Industries	H. L. Hind.
Foods	G. W. Monier-Williams.
Sanitation and Water Purification	J. H. Johnston.
Fine Chemicals, Medicinal Substances, Essential Oils	H. King.
Photographic Materials and Processes	W. Clark.
Explosives	J. Weir.

GLASGOW SECTION

The opening meeting of the session was held on October 22, and a cordial welcome was given to Mr. D. A. MacCallum on taking the chair as the chairman of the section.

The chairman, before introducing the lecturer for the evening, appealed for the active support of the members of the Section in an effort to strengthen the membership of the Society. A paper on "Process Records and their Bearing on Plant Efficiency" was then read by Mr. J. Adam Watson, A.C.G.I., of the North British Rubber Co.

The lecturer first directed attention to the value of daily returns of the output of any manufacturing plant in order to discover the efficiency of the operations and of applying remedial measures where unprofitable working was evident. Process returns could be discussed under three headings—(1) the objects to be attained; (2) the information required; and (3) the method of using the information gained in order to attain the ends aimed at. There were many points in the working of a process upon which information was required, and these might be summarised as (1) the average efficiency of the plant as a whole; (2) the average efficiency of the individual parts of the plant in as great detail as might be desired; (3) the maximum efficiency under working conditions; (4) the possible and probable output; (5) the incidence of loss of efficiency; (6) the cost of the whole process in materials, labour and power; (7) the cost of the individual operations; (8) the variation of cost with changes in labour rates and value of materials.

In elaborating his points, Mr. Watson maintained that the over-all efficiency of a plant could be more easily obtained from daily or weekly returns than from stock sheets prepared at intervals of six or twelve months. The kind of information required to prepare the reports and estimates included records of the amount of material handled in each department, the amount of plant working, the number of hands employed and, where possible, the readings of power meters.

It would obviously be somewhat difficult to obtain these reports from foremen at first, but the system, once satisfactorily established, not only worked well but smoothly. Having obtained such returns, it was imperative to present the returns in a form that would appeal to the management. This was attained by reducing the mass of figures to a form known as the flow-sheet. The flow-sheet presented in terms of unit quantity of the final product, the quantities of material used at each stage of the process together with details of the process. The examination of regularly prepared flow-sheets revealed the interdependence of different sections; the lack of supervision at any particular stage; and enabled the management to concentrate upon the defects which may thus be rendered evident. The conversion of flow-sheets prepared in terms of material to a tabulated statement of cost was easy, and the system was elastic in application.

Many of the difficulties which arise in compiling the flow-sheet—such as allocation of power consumption—were discussed. Once such a system had been in operation for some time the advantages became obvious, and the system afforded a basis upon which instructions could be issued to the buying department; upon which suggestions may be made regarding suitable raw materials; and upon which research could be instituted.

The system adopted at H.M. Factories was used to illustrate the method of recording and the formulation of flow-sheets; and the report used by the Explosive Propellant Supply Department was quoted to show the large economy such a system made possible.

In the discussion, several speakers indicated the benefits which they had derived from the introduction of a system of process records. An interesting point was raised as to the effect of such a system of process records on the attitude of managing directors towards research work, and especially if such records were applied to the output of a works research laboratory.

Amongst other points raised in discussion were the payment of bonus according to records, the psychological effect of introducing a recording system and the attitude of Trade Unionism towards these records.

YORKSHIRE SECTION

Dr. L. L. Lloyd presided at the annual general meeting held in Leeds on October 20, when the following officers were elected:—*Chairman*, John Evans; *Vice-Chairman*, B. A. Burrell; *Hon. Local Secretary and Treasurer*, Prof. Comber, and the vacancies in the committee were filled by Dr. Forster, Prof. Ingold, Dr. L. L. Lloyd, D. McCandlish, and W. McD. Mackey. Mr. John Evans then took the chair, and a vote of thanks was passed to the past chairman and committee.

The section was favoured by an address from the President, Mr. W. J. U. Woolcock, C.B.E., on the present position and responsibilities of the Society. He said that, in view of the fact that the annual meeting was to be held in Leeds next year, he was pleased to be there and to have a frank talk with the Section. The responsibility on the Section was a heavy one, but the Society occupied a unique position and its development was of considerable importance to the community and the chemist. He initially dealt with finance which had been giving the Council a good deal of anxiety. £5000 had been taken from the accumulated funds and devoted to the development of the *Journal*—a policy which could be submitted with confidence to any member of the Society. This year the Council had looked very closely and estimated that they would finish with an expenditure of £4000 less than in the previous year—not a bad record for twelve months' work. There was in existence a House Committee having no definite place, date or duty, but which at the call of the President watched the whole of the business interests of the Society. As to the *Journal*, which was one of the principal reasons for the existence of the Society, the establishment of the Bureau of Abstracts, in conjunction with the Chemical Society, had resulted in a saving to the two Societies. The Transactions

initially depended on the Sections, and he had noted there were not many contributions from Yorkshire recently. No really suitable paper was ever refused publication. He had been told, in violent language, opinions on *Chemistry and Industry*. The Council did not start it with the idea that there was plenty of room for a new *Journal*, but it had a duty to carry to all members a certain amount of scientific information, and to do this required careful organisation. The cost of the 52 numbers for 1923 was just about 4 guineas, for 1924 the estimate was £3 10s.—for a subscription of 50s. From these figures the importance of providing a *Journal* which would carry advertisements and appeal to firms was apparent, and he stated that by establishing *Chemistry and Industry* the Council was satisfied that they were on right lines, and that firms advertising thought it better than the *Review*. The President, after referring to the racy Editorials, stated that the Market Report was so good that other papers were pleased to copy it, a tribute to the *Journal*. The correspondence columns were fairly well used and the papers which, although not suitable for the Transactions, were frequently very good. He appealed, however, for more news of the Sections to be sent to Dr. Miall.

The Council had taken the definite step of suspending for 1925, the Entrance Fee, to give sections the opportunity of getting a large influx of new members, and this was looked for especially in Yorkshire, in view of the forthcoming Annual Meeting in Leeds. Progress would depend on the work of the Sections, and the duty of organising to promote public appreciation of the value of the British Chemical Industry was one of the main methods which made progress possible. The Section had a wonderful opportunity to help, and he thought that the next Annual Meeting would be one of the best, if not the very best ever held. The date fixed provisionally was July 14, and Prof. Cobb had been appointed Conference Secretary. The President's final advice, was not to overdo the functions; let them be good, but no 8 a.m. to 2 a.m. days.

The ensuing discussion was as frank as the President's talk. Prof. Cobb, Messrs. Branson, Read and Burrell asked for further information on the decision to publish weekly, as there was a distinct impression that it was a mistake. The present form of the Abstracts was dealt with by Dr. Forster, and Messrs. Pickering and Robertson. Mr. Finn was doubtful as to the multiplication of chemical activities and referred especially to the Chemical Engineering Group, and this multiplication of Societies was referred to as one of the difficulties in securing members. The question of electing associate members as a method of interesting young chemists was raised by Dr. Parker; the circulation of *Chemistry and Industry* was asked for, and the matter was criticised; it was emphasised that articles on present chemical trade problems would appeal far more to industrialists than ones on alchemy or the early history of antimony, and funny Editorials were deprecated.

In reply to the discussion, the President stated that they had to consider many factors in publishing to keep within the postal rate, and to preserve the balance of the various parts, but the main reason for doing what they did was to carry information quickly to members in a form which would stop the decline in advertisement revenue, and the result of the 25 per cent. increase covered the extra cost in publishing weekly. It was infinitely better to have the Chemical Engineering Group inside the Society; they were exceedingly energetic and frequently brought new members. He looked forward to a decrease in the subscription when trade improved, and the Abstracts were produced by the co-operation of all chemical societies. The Bureau would develop, but certain difficulties had first to be overcome. The insufficiency of the Abstracts in Analysis he would bring before the Council.

The meeting concluded with a hearty vote of thanks to Mr. Burrell for his many years of service as Local Secretary.

EDINBURGH AND EAST OF SCOTLAND SECTION

During the Session 1924–25 all the meetings of this Section will be held jointly with the local Section of the Institute of Chemistry.

The first joint meeting was held in Edinburgh on October 21, at 8 p.m., Dr. Alexander Lauder, Chairman of the Section, presiding.

Mr. W. J. U. Woolcock, C.B.E., President of the Society of Chemical Industry, delivered an address on "Co-operation in Chemical Science." Mr. Woolcock gave an account of the activities of the various chemical bodies in organising the exhibits in the Chemical Hall at the British Empire Exhibition, and pleaded for a closer co-operation, not only between industrialists and chemists, but also between the various Societies.

Dr. J. P. Longstaff, General Secretary of the Society, described the activities of the Society and outlined the possible modes of expansion. In the interesting discussion which followed various suggestions were put forward for further co-operation between the various societies interested in chemistry.

Prior to the meeting Mr. Woolcock, Prof. G. G. Henderson, F.R.S. (President of the Institute of Chemistry), and Dr. Longstaff were the guests of the Section at a dinner in the North British Station Hotel.

OTTAWA SECTION

On October 14, the occasion of the brief visit to the Section of Dr. E. F. Armstrong, Past-president of the Society, a hurried luncheon meeting was held at the University Club, with fifteen members present. After the luncheon Dr. Armstrong clearly outlined the position of the Society in England, and emphasised the interest of the parent Society in the Canadian Sections, indicating that the Council was prepared to assist the local Sections, in every possible way, to meet their difficulties. Several of the members present offered suggestions which might tend to increase the interest in and usefulness of the Society. The Section felt honoured in this

visit of Dr. Armstrong, and it is confidently expected that it will stimulate interest in the activities of the Section. The chairman, Dr. A. E. Macintyre, expressed to Dr. Armstrong the thanks of the Section for his visit.

ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS

The Council met at the offices of the Association on October 9, 1924. There were present Mr. D. Milne Watson (in the chair), Sir Harold Boulton, Bart., Sir John Brunner, Bart., Mr. W. H. Dawson, Mr. E. V. Evans, Mr. C. A. Hill, Sir Max Muspratt, Bart., Sir William Pearce, Mr. R. G. Perry, Dr. Alfred Ree, Rt. Hon. J. W. Wilson, Mr. R. M. Bewick, Mr. E. J. Boake, Mr. N. H. Graesser, Mr. T. Miller-Jones, Mr. A. Ross Mitchell, together with the General Manager.

Trade Marks, Patents, and Designs Federation.—Dr. Ree reported that he had gone carefully through a memorandum which had been received from the Trade Marks, Patents, and Designs Federation, but did not consider the proposals of sufficient importance to call a meeting of the Patents Committee. He had, however, consulted a number of the members through the post, and their opinion was that until the project of an International Patent Law was closer to realisation the time was not ripe for these proposals. The Council adopted this view and decided to inform the Federation accordingly.

British Trade Propaganda in Scandinavia and Northern Europe.—The General Manager reported that he had had an interview with Mr. Everard Fry, who is at present in England, endeavouring to interest British firms in British trade propaganda in Scandinavia and Northern Europe. He understood that the Dutch, French, Swiss and Belgians had already made an intensive propaganda to capture the trade lost by Germany, with the result that the British proportion has declined from 27 per cent. to 16 per cent. The British trade propaganda is being carried out through the *Berlingske Tidende*, the official organ for shipping and industry. The Council instructed the General Manager to bring this to the notice of members in the Proceedings of Council, and to ask any firms interested to communicate with him.

Census of Production.—The General Manager read a letter from the Board of Trade with regard to the census of production which is to be taken for the year 1924, and asking for the observations of the Association on the draft schedule. The Council referred the matter to a committee consisting of the Chairmen of the Groups or their nominees.

Films for Ch[illegible]cal Industry.—The Council received and accepted [illegible]eral Manager's report as to the publicity w[illegible]een given to the films, "Coal and its Pr[illegible]d "Heavy Chemicals." He stated tha[illegible]s had already been shown in over 100 cl[illegible] over the Kingdom, and, in addition, he [illegible]ing frequent requests for the loan of the[illegible]m various scientific bodies and individual fir[illegible]

Federation of British Industries Grand Council.—The Council received an application from the Federation of British Industries to nominate 13 representatives to the Grand Council for Section I of Main Group 9. It was stated that Sir John Brunner and Sir Max Muspratt had already been nominated to represent the individual firms. The Council nominated last year's representatives, as follows:—Dr. E. F. Armstrong, Sir Harold Boulton, Bart., Messrs. F. H. Carr, Kenneth Chance, W. H. Dawson, E. V. Evans, C. A. Hill, D. Lloyd Howard, Dr. P. C. C. Isherwood, Messrs. T. Miller-Jones, R. G. Perry, A. Ross Mitchell and W. J. U. Woolcock.

British Empire Exhibition.—The General Manager stated that he was still unable to say definitely whether the Exhibition would be continued next year.

Committee on Industry and Trade.—The General Manager stated that he was endeavouring, through the various groups, to get the necessary evidence, and drew particular attention to Group IX Report. It was agreed that this report should form the basis of the Memorandum of the Association, and the Council instructed the General Manager to continue to collect evidence and write to the Secretary of the Committee saying that this could not be ready until the beginning of December.

Factories Bill.—The Council considered that although, in view of the present political situation, the Factories Bill was not likely to come before Parliament in its present form, similar legislation would undoubtedly be brought forward in the future. It was, therefore, decided that the matter should not be dropped, but that the General Manager should continue to get the considered views of the members.

Methanol.—The Council instructed the General Manager to take such action as was possible to bring the word "Methanol" as a substitute for "Methyl Alcohol" into common use.

INSTITUTE OF CHEMISTRY

A meeting of the Huddersfield Section was held on October 20, Dr. H. H. Hodgson in the chair, and there was an attendance of 28.

The business of the annual general meeting was first disposed of. It was unanimously decided to present five guineas from the balance in hand to the Benevolent Fund of the Institute. Dr. A. E. Everest and Dr. L. G. Paul, the two retiring members of the Committee, were re-elected for a period of three years. Certificates were presented to the following new local associates by the chairman: Messieurs. J. A. Edge, J. T. Howarth, C. F. Myers and L. [illegible] Scorah. The chairman then called upon Mr. M[illegible] the assistant secretary of the Institute of C[illegible] to give his talk on "Chemists' Contracts—[illegible] and Privileges."

Mr. Marlow opened his remarks by stating [illegible] unemployment among members of the Institut[illegible] considerably decreased in the last few months. [illegible] then outlined the essentials of a contract of ser[illegible] showing that it involved promise and acceptance, [illegible] consideration, and that it should be in writing u[illegible]

the work was to be completed in a year or less. The form of the writing was not important except that a contract with a Corporation should usually be under the seal of the Corporation. He also dealt with contracts between partners and so-called co-partnership. A clause requiring whole-time service was only binding when it was specifically stated that no time must be given to other employment. Clauses relating to trade secrets and binding clauses restraining future activities were dealt with fully. With regard to the termination of a contract Mr. Marlow showed that the question of fair notice of dismissal must depend upon the circumstances of each individual case. Other modes of termination were discussed—bankruptcy, dissolution of partnership, illness, death or default. An expired contract continued until it was definitely terminated. Contracts should be stamped within fourteen days of being made. Any restraint on future activities must be balanced by consideration, and the restraint should be reasonable.

A discussion followed in which Messrs. Tatum, Morley, Jones and Foster took part. In answer to Dr. Morley, Mr. Marlow stated that the period of restraint on future activities dated from the cessation of employment, and not from the expiry of contract. Mr. Foster suggested that a Committee of the Council of the Institute should consider contracts with binding clauses with a view to rectifying hardships. Dr. Paul, in proposing a vote of thanks to Mr. Marlow, paid a tribute to his handling of a difficult subject. [illegible] Simmons, in seconding the vote of thanks, urged [illegible]t the adaptability of the chemist would, if gener[illegible]wn among employers, considerably reduce [illegible] hardship of binding clauses restricting future activities. Dr. Everest enlarged upon the adaptability of the chemist. A properly trained chemist who kept himself reasonably up to date need not limit himself to the branch of the science in which he had been employed for a term of years. The vote was put and passed with acclamation.

BIOCHEMICAL SOCIETY

A meeting was held in the School of Biochemistry, Cambridge, on October 25, and the following papers were read:—

1. The Fractional Ultrafiltration of Plasma Proteins, by A. B. Anderson. An account of preliminary experiments in which human plasma was ultrafiltered through collodion membranes of differential permeability, the proteins in the filtrate and residual fluid being estimated quantitatively. Membranes were obtained permeable to globulin to a large extent, and impermeable or only very slightly permeable to albumin.

2. The Carbohydrate and Fat Metabolism of Yeast, by Dorothy Hoffert and Ida Smedley MacLean.

3. The Isolation of Spermine and its Chemical [illegible]position, by H. W. Dudley, M. C. Rosenheim, [illegible]O. Rosenheim. The base spermine has been [illegible]d as phosphate by a variety of methods from [illegible] (0·006 per cent.), ovary (0·014 per cent.), [illegible] (0·011 per cent.), pancreas (0·018 per cent.), [illegible]d (0·003 per cent.), thymus (0·006 per cent.), [illegible] (0·007 per cent.), and distillers' yeast (0·007 per cent). Attempts to find it in serum, blood, milk and bakers' yeast gave negative results. The free base is a crystalline, hygroscopic solid, melting between 40 and 50° C., and boiling *in vacuo* without decomposition. It is fairly volatile with steam. The most important salt of spermine is the phosphate, which is characterised by extreme insolubility in water. Analyses of this salt and of the hydrochloride (m. pt. 310°), picrate (m. pt. 250°), gold salt (m. pt. 225°), platinum salt (m. pt. 245°), and benzoyl derivative (m. pt. 155°), indicate that spermine is an isomer of cadaverine ($C_5H_{14}N_2$). Determinations of the molecular weight of the benzoyl derivative by Beckmann's and Rast's methods agree, however, with the formula, $C_{10}H_{26}N_4$ for the base.

The identity of the spermine from animal organs with that from semen has been proved by chemical and crystallographic methods.

4. The Influence of Mineral Waters upon Urinary Excretion, by G. L. Peskett and P. C. Raiment. The object of the experiments described was to find whether the ingestion of spa water had any effect upon the volume or the nitrogenous content of the urine of healthy subjects. Four subjects were taken and the results were given for two periods, in the first of which no mineral waters were given; in the second the mineral waters were taken by two of the subjects, the other two being retained as controls. The first period lasted for six days, the second for eleven. Nothing contained in the figures obtained justifies the attribution of any specific effect to the ingestion of mineral waters.

5. The Acid-Soluble Phosphorus Compounds in Milk, by H. D. Kay. It has been found that two phosphoric esters, similar in their behaviour towards heat, enzymes, acids and alkalis to the phosphoric esters found in blood corpuscles, are present in milk, one (the more readily hydrolysable) being present in important quantities. Both esters are present in cow's, goat's, and human milk. In mg. phosphorus per 100 c.c. milk, the more readily hydrolysable ester is present to the average extent of at least 4·6 mg. in cow's milk, 13·5 mg. in goat's milk, and 3·7 mg. in human milk. In the last two milks, these esters account for at least 20 per cent. of the total phosphorus of the milk. Both the more and the less easily hydrolysable ester pass readily through a collodion dialysing membrane which holds back proteins, and which allows methylene blue to diffuse slowly. The identity of these esters is under investigation.

6. The Effect of Ammonium Chloride Acidosis on the Calcium and Potassium of Human Blood Plasma and Urine, by C. S. Hicks, J. B. S. Haldane, G. A. Reay, and E. Watchorn. The ingestion during three days of 80 g. of ammonium chloride, which by conversion of the ammonia into urea liberated 55 g. of hydrochloric acid, doubled the rate of calcium excretion, and quadrupled that of potassium excretion, the latter followed by a period of retention. The serum calcium rose by 5 per cent., and later fell by the same amount; the potassium rose by 25 per cent., and then fell 20 per cent., but the parallelism between serum concentration and urinary output was incomplete.

SOCIETY OF GLASS TECHNOLOGY

The first meeting of the session was held in Sheffield on October 15, the president, Col. S. C. Halse, in the chair.

An address entitled "The Present Position of the Glass Industry in North America" was given by Prof. W. E. S. Turner, D.Sc., who observed that in America the period of trade depression had not been continuous, as was the case in the United Kingdom. In the autumn of 1922, American trade began to improve, and 1923 was a very good year. In February, 1922, trade in general began to fall off, and a very dull period still persisted. The cut-glass industry had almost entirely died out in America, but coloured glass was finding a place more and more. There was a distinct improvement in American taste for glassware. At the Steuben works of the Corning Glass Co. some very fine artistic work was being manufactured. Prof. Turner next referred to the gradual disappearance of pot furnaces in favour of tank furnaces. The latter were now being used even for the manufacture of green and blue signal lights, and for selenium ruby glass. Electric-light bulbs, except very small or very large bulbs, were now practically all made by machines fed from tank furnaces, the glass being of the soda-lime-magnesia type.

Several noteworthy advances in the glass industry were then noted. During the past few years there had been a very distinct development in the use of blowing machines or press and blow machines. Reference was made to the Westlake machine for thin-walled tumblers, the Hartford-Empire machine for electric-light bulbs, and the great development in the manufacture of light-walled tumblers.

Dealing with sheet glass, Prof. Turner remarked that the Fourcault process had not as yet achieved any considerable success in America. The cylinder process was still in active operation. An epoch-making operation was that developed at the glass works of the Ford Motor Co. This process marked an absolute departure from the use of pot furnaces, as the glass was melted in tanks, and there was continuous rolling between a pair of rollers, the sheet passing down a lehr about 440 ft. long and, subsequently, in sheets, traversed long tables in a continuous belt, where the grinding and polishing were done.

Regarding bottle machines, there was a tendency to replace the Owens machine in favour of the feeder-fed type. There were no striking advances in feeding devices, the Hartford Empire feeder being the most in favour, followed by the W. J. Miller. One novelty in operation was the use of a rotating plunger, especially when making large ware.

Prof. [illegible]ner then dealt with the problems of furnac[illegible] furnace efficiency. This was one of the fore[illegible] problems discussed by glass manufac-tur[illegible] average life of a tank furnace operated [illegible] was 11 to 13 months. A table was [illegible]wing for a number of factories the [illegible] rate of fuel consumed to glass melted. [illegible]eral fa[illegible]es could show ratios as low as 0·6. Finally, a de[illegible]ription was given of heatless lehrs.

PERSONAL AND OTHER ITEMS

The Centenary of the Physikalisch Verein at Frankfurt was celebrated on October 24. The history of the Verein is associated with well-known names such as those of R. Böttger, who carried out his work on gun cotton, and on the derivatives of anthracene, in the Institute; of Bernard Lepsius; and of Martin Freund, who carried out his researches on the alkaloids when at Frankfurt. In addition, Richard Lorenz was the first to occupy the chair of physical chemistry founded by the Verein in 1909.

The degree of D.Sc. has been conferred by the University of London on Mr. G. E. Foxwell, for his thesis entitled "The Flow of Fluids treated Dimensionally," and on Miss F. M. Hamer, for a thesis entitled "The Synthesis of an Azocyanine," and other papers.

Prof. H. B. Baker has been appointed to represent the Faculty of Science on the Senate of the University of London, in place of Dr. A. N. Whitehead, resigned.

The late Mr. J. Maddocks, a director of the Firth-Brearley Stainless Steel Syndicate, Ltd., left estate of the gross value of £63,933, with net personalty, £58,466.

Mr. P. K. Malin has succeeded Mr. E. D. Winkworth as president of the Semet Solvay Co., the Solvay Process Co., and the Atmospheric Nitrogen Co., all companies which are subsidiaries of the Allied Chemical and Dye Corporation.

Mr. J. R. Withrow has been appointed professor of chemical engineering and head of the new department of chemical engineering at Ohio State University, Ohio.

Mr. E. Barclay Hoare has been elected master of the Distillers' Company, and Mr. O. Satchell has been elected master of the Painters' Company.

Mr. J. P. Cockcroft, M.Sc., has been appointed lecturer in electrochemistry in the Faculty of Technology of the University of Manchester.

Mr. G. A. Reay (University of Aberdeen) has been elected to a research studentship in biochemistry at Emmanuel College, Cambridge.

We regret to announce the death of Mr. J. W. Spence, a member of the Society of Chemical Industry since 1883.

Mineral Production of New South Wales, 1923

The annual report of the Department of Mines for 1923 shows the record figure of £16,291,416, an increase of £2,016,646, as compared with 1922. The following are the figures of production for 1923:—Alunite, 998 tons; arsenic, 11,493 t.; asbestos, 204 t.; bismuth (metal and ore), 6 t.; chrome, 1192 t.; clays, 64,653 t.; coal, 10,487,513 t.; coke, 580,374 t.; copper (ingots, matte and ore), 1261 t.; diamonds, 175 carats; dolomite, 5059 t.; gold, 18,833 oz. fine; iron, 94,350 t.; iron oxide, 2716 t.; lime, 40,669 t.; limestone flux, 131,843 t.; magnesite, 6130 t.; manganese ore, 2556 t.; marble, 225 t.; molybdenite, 9·5 t.; platinum, 586 oz.; portland cement, 223,852 t.; silica, 18,623 t.; silver, 107,682 oz.; silver-lead ore, concentrates, etc.,

241,761 t.; oil shale, 1207 t.; tin (ingots and ore), 896 t.; wolfram, 2 t.; zinc concentrates, 426,049 t. Coal represents half the total value, silver-lead, zinc, portland cement and iron being the next most important products.

American Symposium on Corrosion

At the Baltimore meeting of the American Chemical Society, which will be held during Easter week, the Division of Industrial and Engineering Chemistry will hold a symposium on Corrosion. At the present time the tentative outline of the symposium is as follows:—(1) Submerged Corrosion of Metals: (*a*) Iron and Steel; (*b*) Non-ferrous metals. (2) Atmospheric Corrosion. (3) Corrosion of special alloys. It is hoped that the scope of the papers of this symposium will cover the problems of corrosion in the heavy chemical industry, in the special chemical industry, in the marine world, in ordnance equipment, in the oil, mining and other industries. Papers relating to any of these subjects or sub-divisions will be welcomed by the chairman of the symposium, who is Robert J. McKay. Anyone who wishes to present a paper before this symposium should communicate at once with Mr. McKay or the Secretary of the Division.

The Phenol Industry in France

The production of phenol was started in France during the war, and considerable improvements have been made in extraction. A preliminary purification of the tar oil has been found to result in an increased yield, over 88 per cent. of the crude phenols being obtainable as against 19 per cent. in previous practice. Carbon dioxide from lime kilns is also being used instead of sulphuric acid to liberate the phenol from the sodium phenate, the gas passing in counter current with the sodium phenate at 100° C. to avoid the formation of sodium bicarbonate. In investigations on the synthesis of phenols, observations on the changes taking place during the distillation of coal in horizontal retorts have given results unfavourable to the theory of Berthelot, who considers that the synthesis takes place during the distillation. In fact, if inclined chambers are substituted progressively for the horizontal retorts an increased quantity of tar is obtained per ton of coal distilled, whilst the content of phenic acid decreases. It thus appears that considering the low rate at which the temperature increases in the centre of the charge, a part at least of the mass is really distilled at a low temperature, and that thanks to the rapid extraction of the gas formed, and to the relatively low temperature of the mains, subsequent changes take place less freely than in the retorts.

The Fuel Congress at Paris

This Congress opened on October 2, under the presidency of Prof. D. Berthelot. The first paper, by M. Roszak, showed how Berthelot's method of hydrogenation had made possible the synthesis of various hydrocarbons, and thus led the way for further work. M. A. Kling discussed the production of synthetic paraffin by the Bergius process and then discussed results obtained by himself and other workers in investigating its claims. The opinion was expressed that the process is sufficiently developed for application on a large scale in France to tar, and other similar fluid products, and that it could yield large amounts of petrol, diesel oils and the like, representing no small fraction of the requirements of the country. The application of the process to coal and similar fuels seemed less advanced but it was thought that the difficulties related largely to the designing of suitable plant.

M. Mailhe, who was one of the first to deal with the problem in France, read a paper on the manufacture of motor fuels from vegetable and animal oils by means of a series of synthetic changes. In the first experiment, linseed oil was treated in the presence of electrolytic copper associated with alumina as catalyst, and the latest work was devoted to the catalytic decomposition of fatty acids. By using magnesium chloride as catalyst M. Mailhe has obtained 68 per cent. of synthetic fuel from a mixture of linoleic, linolenic and arachic acids, from which he has isolated various products ranging from petrol to heavy and thick oils, products consisting of formenic and ethylenic hydrocarbons. Industrial manufacture presents no difficulty but the economics of the process remains to be investigated. It is claimed that from a ton of oil, saponification produces 98 kg. of glycerine and 902 kg. of fatty acids, the fatty acids yielding, by the Mailhe process, 630 kg. of hydrocarbons that yield 15 per cent. of petrol, 20 to 25 per cent. of paraffin, 15 to 20 per cent. of heavy oils, 20 to 25 per cent. of thick oils, and 15 to 20 per cent. of solid oils, worth 1526 francs, or, valuing the 98 kg. of glycerine at 400 francs, a total of 1926 francs per metric ton of oil. As the cost of manufacture is not high the ton of oil must not cost more than 1500 francs, whereas at present low-grade oils are worth over 3000 francs per ton. The industrial application of the process thus seems only possible with very cheap vegetable oils. Synthetic fuel has also been obtained from beeswax and chlorophyll, this last result suggesting that in time a new branch of the cellulose industry will be established.

M. E. Goutal, describing the Andry-Bourgeois and Olivier process, stated that starting from water-gas derived from lignite coke, these authors obtained liquid and gaseous hydrocarbons. The interest of the process lies rather in the nature of the catalysts employed and the arrangement of the plant. Worked on a semi-industrial scale, the process has yielded a synthetic fuel which after hydrogenation gives a light petrol of density 0·76 and with a heat value of 11,539 calories per kg.

On October 3, M. G. Lumet spoke on the use of vegetable oils as motor fuel, and the various aspects of the problem of a national fuel in relation to agriculture were considered by various speakers. M. du Boistesselin stated that better management of French forests would increase the production of wood charcoal by 450,000 tons, an increase which would obviate the necessity for importing petrol. M. Herbillon observed that in Morocco there was an over-production of wood charcoal as the forest companies were obliged by law to carbonise all the waste from working. M. Auclair described the use

of charcoal-gas generators on lorries and pointed out that this application only had the result of raising the price of charcoal. M. Goutal suggested that wood charcoal could be replaced by wood briquettes, which, after successive carbonisation would fetch a lower price than charcoal, but being six times more dense would yield 250 calories more per kg. than the charcoal. M. R. Duchemin pointed out that industrial carbonisation necessitated the sale of by-products if charcoal were to be sold cheaper; whereas the industry already felt the competition of synthetic acetic acid. The difficulties of estimating the world resources of petroleum were discussed by M. Pineau, who thought it was premature to assign any date when the deposits would be exhausted. There was no reason to suppose that new deposits would not be discovered.

Other papers read were by M. Gramme on "Colloidal Fuel," and by M. Guiselin on the "Mechanism of the Catalytic Manufacture of Synthetic Fuels."

Smoke Abatement Conference

This Conference, to be held in the Town Hall, Manchester, from November 4–6, will open with a business meeting in the City Hall, Deansgate, Manchester. The opening of the Exhibition will take place on November 4, at 11.30 a.m., by the Rt. Hon. the Lord Mayor of Manchester, and lunch for municipal delegates at the Town Hall will commence at 1 p.m. The following papers will be read at the Conference:—"Air Pollution," by Dr. J. S. Owens; "Diagrams on Measuring Atmospheric Pollution in a Lancashire Town," by Dr. J. R. Ashworth; "Effect of Atmospheric Impurities on Buildings," by Sir F. Baines; "The Work of the Departmental Committee on Smoke Abatement," by Prof. J. B. Cohen, F.R.S.; "A Description of the Smokeless Fuel Plant for Glasgow," by R. Maclaurin; "Some New Aspects of Low Temperature Distillation," by H. Nielsen; "Coalite" (Standard Smokeless Fuel), Town Gas and Oil Supply, by the Rt. Hon. G. H. Roberts, and P. C. Pope; "Smoke Legislation in England and America," by J. W. Graham; "The Possibilities of Smoke Prevention under the P.H.A., 1875," by R. M. Rowe; "The Effect of Light on Health," by Prof. L. Hill and Dr. R. Veitch Clark; "Complete Gasification of Coal: its bearing upon Smoke Prevention and Fuel Economy," by T. R. Wollaston; "Pulverised Coal," by Dr. J. T. Dunn; "The Smoke Inspector and the Cost of Production," by H. G. Clinch; "Smoke Abatement and Boiler Room Economies in relation to the training of Boiler Firemen," by J. T. Hodgson; "Boiler Design," by W. H. Casmey; "Gas Undertakings as Fuel Providers," by Sir A. Duckham; "The Fuel of the Future," by F. W. Goodenough; "Gas Coke—In relation to Industrial and Domestic Smoke Prevention and Fuel Economy," by E. W. L. Nicol; "How Electricity can help in Smoke Abatement," by J. Frith; "The Influence of Electricity on the Domestic Smoke Problem," by J. W. Beauchamp; "The Use of Power other than that produced by Coal," by Prof. Miles Walker; concluding with a Popular Lecture by Ex-Bailie W. B. Smit[illegible] on "The Cost of a Smoky At[illegible]

REVIEW

Modern Cereal Chemistry. By D. W. Kent-Jones, B.Sc. Pp. IX+324. Liverpool: Northern Publishing Co., Ltd., 1924. Price 25s. net.

For generations millers have made good flour and bakers good bread, but their methods have been mainly empirical. Many scientists have worked at flour and bread problems, and much scientific information has been acquired, but no one had been able to state in scientific terms the ultimate cause or causes of good quality. In this connexion much attention has been given to the percentages of nitrogen, gluten, gliadin, glutenin, soluble extract, soluble phosphates, acidity measured by titration, the ratio of gliadin to glutenin, diastatic capacity and so on, but no one of these points, or all of them in combination, accounted satisfactorily for the results obtained in practice. The author, who is a keen and enthusiastic worker attached to a mill, does not appear to have evolved any new or striking conception on fundamentals, but has, in a very readable way, collated a great number of recent publications, mainly American, German, and British, and has done much work in testing and applying the new theories. He says that flour is not merely a powder to be analysed for its constitutent parts but a "coarse dispersion of a dried up hydrogel." Put shortly, the fundamental change in ideas is the recognition that flour, dough, and bread are "substances in the colloidal state." He quotes Mohs as follows:—"It is possible to get two flours having approximately the same percentage of dried albumin hydrogel (protein or gluten roughly) and having almost similar other constituents, and yet the two flours will have very different baking powers, due to the different swelling properties of the hydrogels contained." He attaches the utmost importance to hydrogen-ion concentration and writes thus:—"The importance of acidity in flour and doughs has always been realised, but somehow the old titration results of chemists did not seem to lead to any useful or definite conclusions. This was because chemists were then reporting on the quantity of acid, rather than the intensity of acid, which recent work has shown to be the thing that matters." He elaborates this point to show its importance in practice, and describes at length Bailey's electrometric method of measuring hydrogen-ion concentration. He provides a very useful indicator of how this method of measuring acidity differs from the older ones, by stating that measured by titration "low grade flours showed high percentages of acid" and high grade flours low ones, whereas "the hydrogen ion concentration is the reverse, it being high in the patent (high grade) flours and low in the lower grades." He shows that the so-called ripening of the doughs in baking, hitherto not fully defined, is due, at least mainly, to an increase in hydrogen-ion concentration. Furthermore he explains how several so called "improvers" used in milling and baking operate and justifies them by their effect on this concentration, which in turn affects the colloidal properties of flour and dough. He devotes a chapter to "Vitamins and Flour," another to "Bleaching

and Flour Improvers, and in an appendix gives a very valuable list of "Approved and Tentative Methods of Analysis" approved in August, 1922, by the American Association of Cereal Chemists. When he, a chemist, deals with flour milling technology, he makes mistakes on details. The Indian wheats we get are not "flinty," nor are they nowadays "very dirty"; cockle is not one of the chief impurities in Manitoba, Northern Spring, and Hard Winter wheats—for corn cockle as distinct from seeds, chiefly wild buck-wheat, is almost entirely absent; nor do Pacific wheats as a class yield very white flour, for Wallas, at least, yield very yellow flour. Apart from relatively unimportant errors such as these, the book is most interesting to "cereal chemists and progressive millers," for whom it was primarily written, and should be read by them. The title of the book, however, may be misleading, for beyond very slight references to rye, it deals only with one cereal, wheat and its derivatives.

A. E. Humphries

COMPANY NEWS

ELECTROLYTIC ZINC CO. OF AUSTRALASIA

With the completion of the constructional pro-mme, the capital expenditure will show a marked ine. During the year the capital expenditure £600,000. The output was 44,768 tons of trolytic zinc, in addition to which 154 tons of mium were recovered, together with residues m cadmium plant operations containing 257 tons pper. Supplies of raw material were drawn inly from Broken Hill, and a steadily increasing nage is being derived from the company's Read ebery Mines, Tasmania. The gross profit for year was £456,820, against £401,808 in 1922-23, the net profit was £341,350, against £285,406. is, added to £78,262 brought forward, made ailable £419,612, which has been appropriated as llows:—Debenture sinking fund reserve, £11,560; ation reserve, £40,000; special amortisation , £100,000; dividends Nos. 4 and 5, £169,131 st (£149,115) absorbed last year by dividends 1, 2 and 3; and balance carried forward, 21. Since the close of the period a further end (No. 6) on all preference and ordinary res, absorbing £95,346, has been paid.

RUBBER ROADWAYS, LTD.

The n annual general meeting was held on tober 22, Sir Stanley Bois, chairman, presiding. e activities of the company during the year were viewed by the chairman, who said it was gratifying record that in addition to substantial gifts of rubber ceived from producing companies for laying rubber blocks in Whitehall round the Cenotaph, two companies had given 1000 lb. and 2000 lb. of rubber, respectively, to be applied to experimental purposes. It was regrettable that the rubber blocks laid in Whitehall had to be removed after a test of eight months, the reason being that whereas similar blocks used for the roadways in Holborn and Southwark had proved satisfactory, they were not suitable for a wide thoroughfare like Whitehall where the traffic was not only heavy but very rapid. But whilst such setbacks are inevitably disappointing, each test carried out proved a source of fresh information. Two of the important advantages of rubber roads were the reduction of vibration and noise. The company has liquid assets totalling £34,652 (War Loan £17,455, cash at bank £6709), and its liabilities are apparently limited to deferred shareholders (who are to be allotted further deferred shares in satisfaction) and £2141 on open account.

CELLULOSE HOLDINGS AND INVESTMENT CO.

The net profit in the year to June 30 last amounted to £14,830 (against £4360 in 1922-23). A sum of £534 brought forward is added. The balance of new issue expenses (£851) has been written off, leaving £14,514 to be dealt with. The proposed dividend of 3d. per share, or 25 per cent., free of tax (against nil), will absorb £13,256, and £1257 is to be carried forward. In the revenue account the item "dividend" interest and "Royalty" amounts to £83,972, whilst the last accounts showed "interest and royalty" at £36,987.

LEEDS FIRECLAY CO., LTD.

The net profit for the year ended June 30 was £30,827, after providing for debenture interest, compared with £38,197 for the previous year. A dividend of 5 per cent. is proposed, carrying forward £9704.

CHINA CLAY PRODUCERS, LTD.

An association, with the object of furthering the interests of china-clay producers, has been formed and registered as a company limited by guarantee without share capital, each of the 100 members being liable for £10 in the event of winding-up. No member of the China Clay Producers, Ltd., will be qualified to hold office as a director who is the owner of any business producing British china clay and has not entered into a producer's agreement, or who holds a controlling interest in any company, or is a member of any firm producing British china clay which is not a member of the company.

BRITISH CYANIDES CO., LTD.

At the annual meeting, held on October 15, Mr. Kenneth M. Chance dealt with the causes which resulted in the Company making a loss of £24,991 during the year ended April 30, 1924, the chief reason being the sudden fall in the market value of cyanogen products. When the question of quality was regarded by consumers as being of first-rate importance, the Company was the pioneer in the manufacture of a high-grade sodium cyanide, which was then universally used in the gold-mining industry; but now an American company produced a low-grade cyanide which was sold at a price far below that of the high-grade cyanide, and, with the aid of a tariff of 33 per cent., the American company had captured practically the whole of that trade. The

British Cyanides Co., therefore, had to find a new outlet for the raw material obtained from the gas-works, and had practically to build up a new business, with the result that a great deal of research work had been done and rapid developments had taken place in the process of fixing atmospheric nitrogen, which yielded a chemical which could be used in the vulcanisation of rubber. The new plant for this had been extraordinarily inexpensive to erect, and if it proved successful would overcome all difficulties in connexion with financing the capital outlay required for converting the whole of the Company's sulpho-cyanide into this new chemical. Referring to the liquidation of the British Potash Co., Ltd., Mr. Chance said that he was convinced that the chemical trade in this country would remain incomplete until a potash industry was formed and developed on lines approved by the leading chemical manufacturers of this country and the British Government.

ERINOID, LTD.

The net profits for the year ended August 31 amounted to £27,171 (£17,125 in 1922-23), and £6417 were brought forward. It is proposed to pay a dividend of 7 per cent., less tax (against 4 per cent., less tax), to transfer £10,000 to general reserve (against £5000), and to transfer £4000 to reserve for income tax, leaving £6497 to be carried forward. An agreement has been entered into with the Casein Co. of America to form a company to manufacture Erinoid in the United States. The company will take over the goodwill and connexion of Erinoid, Ltd., in the United States in exchange for an allotment of fully-paid shares representing one-third of the common stock of the new company.

VAL DE TRAVERS ASPHALT CO., LTD.

An intermin dividend for the half-year ended June 30 of 6d. per share, or 2½ per cent., has been declared on shares Nos. 1 to 196,000, payable on November 3.

REPORT

REPORT ON THE ECONOMIC CONDITIONS IN FRANCE. Revised to June, 1924. By J. R. CAHILL, Commercial Counsellor, Paris. Department of Overseas Trade. Pp. 224. H.M. Stationery Office, 1924. Price 6s.

The economic revival which occurred early in 1922 shows no sign of failing (*cf. Chem. and Ind.*, 1923, 700). The reconstruction of devastated areas is practically complete and industries are fully active here an[illegible] other parts; the chief difficulty is a short[illegible] labour, which is being partially met by im[illegible]. The industrial capacity of the country [illegible]ly superior to what it was before the [illegible]ards both natural resources and also m[illegible]ing power. Efforts have been made to im[illegible]ublic finances, and taxation is now nearly thre[illegible]es as heavy as in 1919.

Th[illegible]aluc of imports into France in 1923 was 32,615 mill. fr., and of exports 30,431 mill. fr., each about 50 per cent. greater than in 1923, though the actual bulk increased only by about 8 per cent. in each case. There has been a considerable change since the war in the character of French trade. The recovery of Alsace and Lorraine has rendered unnecessary much of the importation previously made from Germany, such as ores, potash, and textiles. Chemical, metallurgical, and engineering industries have made such progress that imports in these branches are steadily declining, and in several other industries home-produced articles are extending their markets. The woollen trade has been much favoured in its exports by the depreciation of the franc. Great Britain and Belgium continue to be the most important customers of France, each taking exports valued at 4400 mill. fr. Of the imports Great Britain supplied 16·1 per cent. and the United States 15·5 per cent. In both these cases expansion of trade was hampered by fluctuations in the value of the franc.

The coal industry has enjoyed a period of prosperity since the beginning of 1922; output rose from 31·94 mill. t. in 1922 to 38·54 mill. t. in 1923. This is expected to show a further increase and may reach 55 to 60 mill. t. in a few years, so that there will be a big decrease in imports; these reached 30·66 mill. t. last year, of which 18·5 mill. t. came from Great Britain. The danger of stoppage of German supplies had the effect of increasing considerably the home production of metallurgical coke which amounted to 2·3 mill. t. Iron ore production recovered in the middle of the year from the effect of uncertain supplies of coke and still continues satisfactory; 95,000 t. was exported from Lorraine and 230,000 t. from Normandy. The production of iron and steel rose considerably in 1923 to 5·4 and 5·1 mill. t. respectively. The aluminium industry has been very busy during the past two years and is building up a considerable export trade. Before home demands for reconstruction purposes cut down exports, France was one of the principal world's suppliers of cement; with these demands now practically satisfied, and a production in 1923 of 5·9 mill. t., the country will no doubt again enter her old markets. Dyestuff and other chemical industries have made great progress, and home-produced dyestuffs are now thoroughly established. Among heavy chemical exports the chief is potassium chloride. All branches of textiles, except linen and lace, had a prosperous year. The increased demand for artificial silk has led to a great extension of the industry, which now produces at the rate of 3200 t. per annum.

MINERAL OUTPUT IN WESTERN AUSTRALIA, 1923

In Western Australia the value of the mineral output in 1923 was £2,657,950, being £143,676 less than for the previous year. The output was as follows:—Asbestos, 115 cwt.; clay, 34 tons; coal, 420,714 t.; copper ore, 3394 t.; copper ingot, matte, etc., 1057 t.; gold, 504,511 fine oz.; iron ore, 2 t.; lead and silver lead, 3172 t.; lead (pig), 20 t.; magnesite, 22 t.; silver, 109,005 f. oz.; tantalite, 5 t.; and tin, 131 t.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech. ..	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder..	£47 per ton.
Acid Hydrochloric ..	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
mmonia Alkali.. ..	£6 15s. per ton, f.o.r. Special terms for contracts.
leaching Powder ..	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
isulphite of Lime ..	£7 10s. per ton, packages extra.
orax, Commercial—	
Crystal..	£25 per ton.
Powder..	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
alcium Chloride ..	£5 17s. 6d. per ton d/d.
opper Sulphate	£25 per ton.
ethylated Spirit 64 o.p.—	
Industrial	2s. 7d.—2s. 11d. per gallon, according to quantity.
Mineralised	3s. 8d.—4s. per gallon, according to quantity.
ickel Sulphate .. .. / ickel Ammon. Sulphate	£38 per ton d/d. Normal business.
ash Caustic	£30—£33 per ton.
ss. Bichromate ..	5⅞d. per lb.
s. Chlorate.. ..	3d.— ' ' per lb.
lammoniac	£32 per ton d/d.
t Cake.. ..	£3 10s. per ton d/d.
oda Caustic, solid ..	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
oda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton, carr. paid.
Sod. Bichromate.. ..	4¼d. per lb.
Sod. Bisulphite Powder 60/62%..	£17—£18 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. 60/65	About £14 10s. per ton /dd.
Sod. Sulphide cryst. ..	£9 per ton d/d.
Sod Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt. kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	6¼d.—1s. 2d. per lb., according to quality.
Crimson	1s. 4d.—1s. 6d. per lb., according to quality.
Arsenic, Sulphide, Yellow	1s. 11d. per lb.
Barytes	£3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide ..	3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide ..	£30—£33 per ton, according to quantity.
Carbon Black	7d.—7½d. per lb. ex wharf.
Carbon Tetrachloride ..	£60—£65 per ton, according to quantity, drums extra.
Chromium Oxide, green..	1s. 3d. per lb.
Indiarubber Substitutes White and Dark ..	5d.—9½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black	£48 per ton, barrels free.
Lead Hyposulphite ..	7½d. per lb.
Lithopone, 30%	£22 10s. per ton.
Mineral Rubber "Rubpron"	£16 5s. per ton f.o.r. London.
Sulphur	£10—£12 per ton, according to quality.
Sulphur Precip. B.P. ..	£47 10s.—£52 10s. per ton, according to quantity.
Sulphur Chloride ..	4d. per lb., carboys extra.
Thiocarbanilide	2s. 6d. per lb.
Vermilion, pale or deep ..	5s. 1d. per lb.
Zinc Sulphide	7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

There is a general feeling that the fall in price of acetates during the last few weeks has reached its limit. The tendency is now to stiffen again.

Acetate of Lime—	
Brown	£11—£11 10s. per ton.
Grey	£15 per ton.
Liquor	9d. per gall. 32° Tw.
Charcoal	£7 15s.—£9 5s. per ton, according to grade and locality. Demand quiet but price steady.
Iron Liquor	1s. 7d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor	10d.—1s. per gall. 14/15° Tw.
Wood Creosote	2s. 9d. per gall. Unrefined.
Wood Naphtha—	
Miscible	4s. 9d. per gall. 60% O.P.
Solvent..	5s. 6d. per gall. 40% O.P. Firmer.
Wood Tar	£4 5s. per ton. Very quiet.
Brown Sugar of Lead ..	£43 per ton.

TAR PRODUCTS

Acid Carbolic—	
Crystals	6¼d. per lb. Quiet.
Crude 60's	1s. 8d.—1s. 10d. per gall. Market flat.
Acid Cresylic, 97/99 ..	2s.—2s. 1d. per gall. Demand steady.
Pale 95%	1s. 9d.—2s. per gall. Better enquiry.
Dark	1s. 8d.—1s. 10d. per gall. Fairly steady.
Anthracene Paste 40% ..	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained	6½d.—7½d. per gall. Small demand
Unstrained	6d.—6½d. per gall.

Benzole—

Crude 65's	7½d.—9d. per gall. ex works in tank wagons.
Standard Motor	1s. 1½d.—1s. 3d. per gall. ex works in tank wagons.
Pure	1s. 5½d.—1s. 7d. per gall. ex works in tank wagons.
Toluole—90%	1s. 5d.—1s. 5½d. per gall. Small demand for home consumption.
Pure	1s. 7d.—1s. 9d. per gall. Small demand for home consumption.
Xylol—Coml.	2s. 3d. per gall.
Pure	3s. 3d. per gall.

Creosote—

Cresylic 20/24%	8d.—8½d. per gall. Little demand.
Middle Oil / Heavy Oil / Standard Specification	5¼d.—6¼d. per gall., according to quality and district. Fair business passing. A little more demand for export in bulk.

Naphtha—

Solvent 90/160	1s.—1s. 3d. per gall. Demand good.
Solvent 90/190	11d—1s. per gall. Fair inquiry. Local demand good.

Naphthalene Crude—

Cheaper in Yorkshire than Lancashire. Demand rather better.

Drained Creosote Salts £3—£5 per ton. Demand slightly better.

Whizzed or hot pressed £6—£9 per ton. Demand very poor.

Naphthalene—

Crystals and Flaked	£12—£15 per ton, according to district.
Pitch, medium soft	42s. 6d.—60s. per ton according to district. Plenty of inquiry. Prospects brighter.
Pyridine—90/160	19s. per gall. Steady demand.
Heavy	12s.—12s. 6d. per gall. Market dull.

INTERMEDIATES AND DYES

Business in dyestuffs has been very well maintained this week. Slight reductions have been made in the price of a number of intermediates.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95%	1s. 7d. per lb.
Acid H.	3s. 11d. per lb. 100% basis d/d.
Acid Naphthionic	2s. 2d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	1s. 1d. per lb. Improved demand.
Acid Sulphanilic	9d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd.	1s. per lb. d/d.
Aniline Oil	8d. per lb. naked at works.
Aniline Salts	8½d. per lb., naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base	3s. 11d. per lb. 100% basis d/d.
Benzyl Chloride 95%	1s. 1d. per lb.
p-Chlorphenol	4s. 3d. per lb. d/d.
p-Chloraniline	3s. per lb. 100% basis.
o-Cresol 19/31° C.	4d.—4½d. per lb. Rather quiet.
m-Cresol 98/100%	2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline	3s. per lb.
Dichl[illegible]ine S. Acid	2s. 6d. per lb. 100% basis.
p-D[illegible]benzol	£85 per ton.
D[illegible]niline	4s. 3d. per lb. d/d., packages extra, returnable.
[illegible]ethylaniline	2s. 2½d. per lb. d/d. Drums extra.
[illegible]	2s. 4d. per lb. 100% basis d/d.
α-Naphthol	2s. 5d. per lb. d/d.
Dinitrobenzene	9d.—10d. per lb. naked at works.
Dinitrochlorbenzol	£84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine	2s. 10d. per lb. d/d.
Monochlorbenzol	£63 per ton.
β-Naphthol	1s. per lb. d/d.
α-Naphthylamine	1s. 3½d. per lb. d/d.
β-Naphthylamine	4s. per lb. d/d.
m-Nitraniline	4s. 2½d. per lb. d/d.
p-Nitraniline	2s. 2½d. per lb. d/d.
Nitrobenzene	5½d.—5¾d. per lb. naked at works.
o-Nitrochlorbenzol	2s. 11d. per lb. 100% basis d/d.
Nitronaphthalene	10½d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	3s. 10d. per lb. d/d.
p-Phenylene Diamine	10s. 2d. per lb. 100% basis d/d.
R. Salt	2s. 4d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 2d. per lb. 100% basis d/d.
o-Toluidine	10d. per lb.
p-Toluidine	3s. per lb. naked at works.
m-Toluylene Diamine	3s. 10d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	£47 per ton. Firmer.
Acid, Acetyl Salicylic	3s. 1d.—3s. 3d. per lb., according to quantity. Sales steady. Price firm.
Acid, Benzoic B.P.	2s. 6d. per lb. Cheaper.
Acid Boric B.P.	Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 3½d.—1s. 4d. per lb., less 5% for ton lots. Market still weak.
Acid, Gallic	2s. 9d. per lb. for pure crystal in 2 cwt. lots.
Acid, Pyrogallic, Cryst.	6s. 9d. per lb. Resublimed quality 8s. per lb. Market firm.
Acid Salicylic	1s. 6d.—1s. 8d. per lb., according to quantity. Slightly firmer.
Acid, Tannic B.P.	2s. 10d. per lb. Market quiet.
Acid, Tartaric	1s. per lb., less 5%.
Amidol	9s. per lb. d/d.
Acetanilide	2s. per lb. for quantity. More enquiry.
Amidopyrin	15s. per lb.
Ammon. Benzoate	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	14s. 3d. per lb.
Benzonaphthol	5s. 3d. per lb. spot.
Bismuth Carbonate	10s. 6d.—12s. 6d. per lb.
„ Citrate	10s. 3d.—12s. 3d. „
„ Salicylate	9s.—11s. „
„ Subnitrate	8s. 8d.—10s. 8d. „
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	Market exceedingly firm and prices advancing. Raw materials dearer.
Ammonium	1s. 8d.—1s. 11d. per lb. } According to quantity.
Potassium	1s. 6d.—1s. 9d. per lb. } According to quantity.
Sodium	1s. 7d.—1s. 10d. per lb. } According to quantity.
Calcium Lactate	1s. 6d.—1s. 8d. per lb., according to quantity. Fair demand and steady market.

Chloral Hydrate	4s.—4s. 3d. per lb. Slightly dearer. Spot supplies short.
Chloroform	2s. 6d. per lb. for cwt. lots. Price advanced by 6d. per lb.
Formaldehyde	£46—£49 per ton in barrels, ex wharf London.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free	7s. per lb.
Glycerophosphates—	
Iron	8s. 9d. per lb.
Magnesium	9s. per lb.
Potassium, 50%	3s. 6d. per lb.
Sodium, 50%	2s. 6d. „
Guaiacol Carbonate	10s. per lb.
Hexamine	3s. per lb. Forward prices higher.
Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor.	English make offered, 120s. per oz.
Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. „
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb.
...nesium Carbonate—	
...ht Commercial	£36 per ton net.
...esium Oxide—	
...ht Commercial	£75 per ton, less 2½%.
...avy Commercial	£25 per ton, less 2½%.
...vy Pure	2s.—2s. 3d. per lb., according to quantity. Steady market.
...ol—	
...B.R. recryst, B.P.	60s. per lb. Market much firmer.
...nthetic	26s.—35s. per lb., according to quantity. English make. Increasing demand.
...urials	Market very quiet.
...d oxide	5s. 3d.—5s. 4d. per lb.
...rrosive sublimate	3s. 6d.—3s. 7d. „
...hite precip.	4s. 7d.—4s. 8d. „
...lomel	3s. 11d.—4s. „
...hyl Salicylate	1s. 10d.—2s. per lb. Seasonal increase in demand.
...hyl Sulphonal	24s. per lb. Slightly weaker.
...l	11s. per lb. British make.
...formaldehyde	2s. 8d. per lb. for B.P. quality.
...aldehyde	1s. 4d.—1s. 6d. per lb. in free bottles and cases. Supplies plentiful.
...nacetin	5s. 9d. per lb.
...nazone	6s. 9d. per lb. Slightly lower. Supply exceeds demand.
...olphthalein	5s. 9d. per lb.
...s. Bitartrate—	
.../100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots.
...ass. Citrate	1s. 10d.—2s. 2d. per lb.
...tass. Ferricyanide	1s. 9d. per lb. Quiet.
...otass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Steady market.
...tass. Metabisulphite	7½d. per lb., 1-cwt. kegs included. F.o.r. London.
...ass. Permanganate	7½d. per lb. spot. Forward prices higher.
...uinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. 3d.—5s. 6d. per lb.
Saccharin	63s. per lb., in 50-lb. lots.
Salol	3s. 9d. per lb. for cwt. lots.
Silver Proteinate	9s. per lb. for satisfactory product, light in colour.
Sod. Benzoate, B.P.	2s. 6d. per lb. Supplies of good quality now available.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite—Photographic	£13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.
Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside	16s. per lb.
Sod. Potass. Tartrate (Rochelle Salt)	75s.—82s. 6d. per cwt., according to quantity. Quiet market.
Sod. Salicylate	Fair demand. Powder 2s.—2s. 3d. per lb. Crystal at 2s. 2d.—2s. 5d. per lb. Flake 2s. 6d. per lb.
Sod. Sulphide—Pure recryst.	10d.—1s. 2d. per lb.
Sod. Sulphite, anhydrous	£27 10s. per ton, minimum 5-ton lots, increasing according to quantity, 1-cwt. kegs included.
Sulphonal	15s. 6d. per lb. Little demand.
Thymol	16s. per lb.

PERFUMERY CHEMICALS

Acetophenone	12s. per lb.
Aubepine	15s. 3d. „
Amyl Acetate	2s. 9d. „
Amyl Butyrate	6s. 9d. „
Amyl Salicylate	3s. 3d. „
Anethol (M.P. 21/22° C.)	4s. 6d. „
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 9d. „
Benzyl Alcohol free from Chlorine	2s. 9d. „
Benzaldehyde free from Chlorine	3s. 6d. „
Benzyl Benzoate	3s. 6d. „
Cinnamic Aldehyde—Natural	18s. 9d. „
Coumarin	19s. 6d. „
Citronellol	17s. „
Citral	8s. „
Ethyl Cinnamate	12s. 6d. „
Ethyl Phthalate	3s. 3d. „
Eugenol	10s. „
Geraniol (Palmarosa)	33s. 6d. „
Geraniol	11s. 6d.—18s. 6d. per lb
Heliotropine	6s. 9d. „
Iso Eugenol	15s. 9d. „
Linalol ex Bois de Rose	26s. „
Linalyl Acetate	26s. „
Methyl Anthranilate	9s. 6d. „
Methyl Benzoate	5s. „
Musk Ambrette	50s. „
Musk Xylol	13s. 6d. „
Nerolin	4s. 9d. „
Phenyl Ethyl Acetate	15s. „
Phenyl Ethyl Alcohol	16s. „
Rhodinol	55s. „
Safrol	1s. 10d. „
Terpineol	2s. 4d. „
Vanillin	25s. 6d. „

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.
Anise Oil	2s. 8d. per lb.
Bergamot Oil	16s. 6d. per lb.
Bourbon Geranium Oil	33s. 6d. per lb.
Camphor Oil	65s. per cwt.

Cananga Oil Java	.. 10s. per lb.	
Cassia Oil, 80/85%	.. 10s. per lb.	Dearer.
Cinnamon Oil, Leaf	.. 6½d. per oz.	
Citronella Oil—		
Java 85/90% ..	.. 5s. 10½d. „	Dearer.
Ceylon	.. 3s. 8d. per lb.	Dearer.
Clove Oil	.. 7s. 9d. per lb.	
Eucalyptus Oil 70/75%	.. 2s. 3d. per lb.	
Lavender Oil—		
French 38/40% Esters	32s. 6d. per lb.	Dearer.
Lemon Oil ..	.. 3s. 2d. per lb.	
Lemongrass Oil ..	.. 4s. 6d. per lb.	
Orange Oil, Sweet	.. 11s. per lb.	
Otto of Rose Oil—		
Bulgarian ..	.. 40s. per oz.	
Anatolian ..	.. 18s. per oz.	
Palma Rosa Oil ..	.. 16s. 6d. per lb.	
Peppermint Oil—		
English ..	.. 70s. per lb. Dearer.	
Wayne County	.. 30s. per lb. Higher prices anticipated.	
Japanese ..	.. 18s. 6d. per lb. paid. Practically unobtainable for spot or near delivery.	
Petitgrain Oil ..	.. 9s. 3d. per lb.	
Sandal Wood Oil—		
Mysore	.. 26s. 7d. per lb.	
Australian ..	.. 18s. 6d. per lb.	

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before Dec. 22nd; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on Nov. 6th.

I.—Applications

Ablett, and Shaw and Co. Grinding and/or mixing etc. machines 24,535. Oct. 16.

Armstrong (N. V. Algem. Chemische Productenhandel). Separation of vaporised organic substances from gaseous mixtures. 24,795. Oct. 18.

Coley and Hornsey. Rotary furnaces etc. 24,184. Oct. 13.

Coley and Hornsey. Sealing rotary kilns etc. 24,185. Oct. 13.

General Electric Co., Ltd. Treatment of crystalline substances. 24,384. Oct. 14. (Ger., 3.5.24.)

Heberlein. Prevention of scale etc. in boilers etc. 24,616. Oct. 16.

Imray (Raymond Bros. Impact Pulverizer Co.). Pulverizing mills. 24,607. Oct. 16.

Marks (Maschinenbau-Anstalt Humboldt). Grinding etc. apparatus. 24,274. Oct. 13.

Mongereau et Cie. Pulverising machines. 24,518. Oct. 15. (Belgium, 15.10.23.)

Rigby. Drying. 24,524. Oct. 16.

Stone. Retorts. 24,609. Oct. 16.

Wilputte. Continuous tunnel kiln. 24,181. Oct. 13.

I.—Complete Specifications Accepted

17,667 (1923). [illegible]g. Binding granular and other substances. (200,[illegible])

24,850 (1923). [illegible]ttings and Bodman. Rotary drying apparatus. (223,0[illegible]2.)

II.—Applications

Fairbrother (Jackson Research Corporation). Gasification of coal. 24,231. Oct. 13.

Fairbrother (Jackson Research Corporation). Distillation of carbonaceous material. 24,232. Oct. 13.

Marks (Carbide and Carbon Chemicals Corporation). Processes of rectifying hydrocarbon mixtures. 24,833. Oct. 18.

Weber. Manufacture of briquettes from coke smalls. 24,259. Oct. 13.

II.—Complete Specifications Accepted

17,497 (1923). Sutcliffe. Fuel. (222,931.)

18,705 (1923). Cummins. Gas-retort settings. (222,987.)

20,741 (1923). Hinchley, Greenwood, and White. Rapidly drying peat. (223,011.)

23,259 (1923). Annaratone. Preparing liquid fuels for internal-combustion engines. (217,873.)

28,699 (1923). V. L. Oil Processes, Ltd., Lucas, and Lomax. Methods of refining hydrocarbons. (223,066.)

7509 (1924). Records. Liquid fuel. (223,140.)

10,311 (1924). British Thomson-Houston Co. *See* X.

III.—Application

Marks (Carbide and Carbon Chemicals Corporation). 24,833. *See* II.

III.—Complete Specification Accepted

28,699 (1923). V. L. Oil Processes, Ltd., Lucas, and Lomax. *See* II.

IV.—Applications

Carpmael (Farbenfabr. vorm. F. Bayer & Co.). Manufacture of azo dyestuffs. 24,592. Oct. 16.

Farbenfabriken vorm. F. Bayer & Co. Manufacture of dyestuffs. 24,753. Oct. 17. (Ger., 18.10.23.)

Hefti and Schnorf. Production of acridine derivatives etc. 24,305. Oct. 14.

Morton, Harris, Jones, Wilson. Wylam and Morton Sundour Fabrics, Ltd. Dyes and dyeing. 24,608. Oct. 16.

IV.—Complete Specifications Accepted

17,822 (1923). Barnard. Manufacture of dyestuffs. (222,947.)

20,045 (1923). Eberlein. Manufacture of silicates of the basic dyestuffs. (201,940.)

V.—Complete Specifications Accepted

14,571 (1923). Lilienfeld. Manufacture of cellulose solution. (212,864.)

6125 (1924). Akt.-Ges. für Anilin Fabrikation. Washi[illegible] artificial silk. (212,911.)

13,899 (1924). Hartogs. Spinning viscose. (223,171.)

VI.—Applications

Brandwood. Dyeing etc. yarns in wound form. 24,54[illegible] Oct. 16.

Morton, Harris, Jones, Wilson, Wylam and Morto[n] Sundour Fabrics, Ltd. 24,608. *See* IV.

Soc. Alsacienne de Produits Chimiques. Dyeing of artifici[al] silk. 24,843. Oct. 18. (Fr., 3.11.23.)

VII.—Applications

Coke and Gas Ovens, Ltd., and Pearson. Neutralisin[g] free acid in sulphate of ammonia. 24,493. Oct. 15.

Coley and Hornsey. Production of magnetic oxide o[f] iron. 24,188. Oct. 13.

Evans. Recovery of ferrous sulphate from waste pickle. 24,171. Oct. 13.

Soc. d'Étude des Agglomérés. Production of pure oxide of zirconium. 24,468. Oct. 15. (Fr., 17.10.23.)

VII.—Complete Specifications Accepted

21,136 (1923). Cooksedge. Manufacture of sodium carbonate. (223,015.)

30,988 (1923). Deguide. Manufacture of barium cyanide. (223,082.)

854 (1924). Comp. Gén. des Produits Chimiques de Louvres. Manufacture of zinc sulphide. (209,757).

3763 (1924). N. V. Stikstofbindings Industrie Nederland. Manufacture of ammonia from products containing cyanides. (211,857).

VIII.—Applications

General Electric Co., Ltd. Readily fusible glasses and enamels. 24,392. Oct. 14. (Ger., 5.5.24.)

Guy. Manufacture of saggers. 24,165. Oct. 13.

Soc. d'Etude des Agglomérés. Refractory products. 24,469. Oct. 15. (Fr., 17.10.23.)

Soc. d'Etude des Agglomérés. 24,470. *See* IX.

X.—Applications

Girouard. Manufacture of Portland cement. 24,343. Oct. 14.

Mitchell. Manufacture of cement. 24,763. Oct. 18.

Soc. d'Etude des Agglomérés. Refractory cement. 24,470. Oct. 15. (Fr., 29.10.23.)

Stone. Manufacture of Portland cement. 24,610. Oct. 16.

.—Complete Specifications Accepted

17,238 (1923). Caccia. Manufacture of lime-sand concrete. 22,923.)

17,484 (1923). Douzal. Manufacture of artificial marble. 07,497.)

—Applications

Coles. Recovery of zinc from zinc residues. 24,563. t. 16.

Coley and Hornsey. Manufacture of iron from iron ores. 189, 24,190, 24,191, 24,194. Oct. 13.

oley and Hornsey. Manufacture of steel. 24,172. . 13.

oley and Hornsey. Manufacture of alloys. 24,193, 96. Oct. 13.

oley and Hornsey. Manufacture of iron. 24,195, 24,197. 14.

vans. 24,171. *See* VII.

ournié. Production of iron and steel. 24,287. Oct. 13.

Vado (U.S. Smelting, Refining and Mining Co.). Purifying onial lead alloys etc. 24,595. Oct. 16.

omplete Specifications Accepted

221 (1923). Barker (Vegetable Oil Securities Co.). ratus for making metal catalyst. (222,922.)

,311 (1924). British Thomson-Houston Co. Malleable ductile tungsten composition or alloy suitable for the facture of lighting bodies or filaments. (215,348.)

pplications

kaldy. Anodes. 24,584. Oct. 16. (U.S., 16.10.23.)

vy. Dry batteries. 24,508. Oct. 15.

Nitt. Electrolysing fused baths. 24,265. Oct. 13.

—Complete Specifications Accepted

2,383, 12,715 (1923). Soc. Anon. le Carbone. Liquid-t coating on porous bodies of electrodes of batteries or trolysing-apparatus. (198,656 and 206,471.)

.—Complete Specifications Accepted

502 (1923). Bollinghame. Emulsive and detersive agents, d the manufacture thereof. (222,602.)

17,221 (1923). Barker (Vegetable Oil Securities Co.). e X.

III.—Application

Farbenfabriken vorm. F. Bayer und Co. Manufacture of thopone. 24,754. Oct. 17. (Ger., 30.11.23.)

XIII.—Complete Specification Accepted

19,595 (1923). Naugatuck Chemical Co. *See* XX.

XIV.—Application

Fraser, Rissik, Fraser and Co., and Shaw and Co. Producing rubber etc. solutions. 24,534. Oct. 16.

XVII.—Application

Carpmael (Farbenfabr. vorm. F. Bayer und Co.). Manufacture of esters of saccharides etc. 24,835. Oct. 18.

XIX.—Application

Krempf. Treatment of protein matter. 24,511. Oct. 15.

XIX.—Complete Specifications Accepted

21,018 (1923). Sauer. Purifying and sterilising liquids and gases. (202,654.)

21,270 (1923). Siebert. Separating scale-forming salts from boiler feed-water. (204,027.)

1861 (1924). Rushen (Siemens-Schuckertwerke Ges.). Treatment of green fodder. (223,010.)

XX.—Applications

Bloxam (Haco-Ges. Akt.-Ges.). Manufacture of compounds of alkaloids. 24,377. Oct. 14.

Carpmael (Kaiser). Manufacture of formaldehyde. 24,755. Oct. 17.

Vidal. Preparation of fatty acids etc. 24,822. Oct. 18. (Fr., 19.10.23.)

XX.—Complete Specifications Accepted

19,595 (1923). Naugatuck Chemical Co. Manufacture of formaldehyde condensation products of aliphatic amines, and products obtained thereby. (207,499.)

27,613 (1923). Pollak. Manufacture of condensation products from formaldehyde and urea, thiourea, or their derivatives. (206,512.)

GENERAL NOTES

Official Trade Intelligence

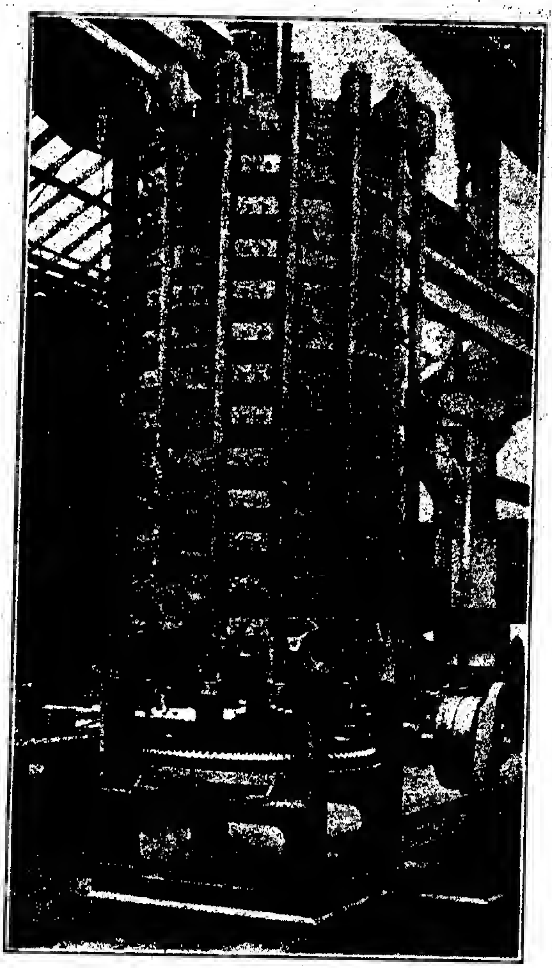
The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number:—*British India*: Steel (Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E. 1). *Egypt*: White metal (Inspecting Engineer, Egyptian and Sudan Governments, Queen Anne's Chambers, London, S.W. 1, Ref. No. E.S.R./4331). *Italy*: Copper clad and chrome nickel wire (444). *Netherlands*: Glass (445). *Poland*: Tin, tinplate, steel (448); Chemicals, rubber (449). *South Africa*: Indiarubber (441). *Sweden*: Paper (450). *Turkey*: Leather, hides, oils (451).

Notes on Plant and Products

Messrs. Thomas Tyrer & Co. have issued the October, 1924, edition of their price-list of "Sterling" Brand Chemicals. A wide range of products is stocked, including A.R. Chemicals, volumetric solutions, and a large variety of inorganic salts both pure and commercial, and organic compounds such as benzaldehyde, ethers, and hydrogen peroxide. The list gives prices for quantities ranging from 1 lb. to 1 cwt.

An Oil Cooler of novel design is now being made by Messrs. A. F. Craig & Co., Ltd., Caledonia Engine Works, Paisley, for which several advantages are

claimed over the ordinary type of plant. The machine, which is due to Mr. J. Moore, the superintending engineer of the Burmah Oil Company's refineries, operates continuously, is extremely compact and embodies every refinement that can pass the test of practice. It consists of a vertical series of shallow circular cells (the number depending on the capacity), bolted together and supported on a frame which carries gearing and a scraping device.



THE "MOORE-BURMAH" OIL COOLER

Each cell comprises an upper and lower chamber, the upper chamber being closed above by the bottom of the next higher cell. The oil to be cooled flows through the upper chambers only, in series from top to bottom, whereas the cooling medium, brine, flows through the lower chambers in series in the reverse direction. The paraffin or other wax (the coolers being suitable for treating any mineral, animal, or vegetable oil) is deposited on the smooth inner surfaces of the cylinder, and is scraped off as it forms by well-designed, adjustable spring scrapers. If required, refrigeration can be saved by using some of the top cells as a heat interchanger (as in tubular coolers), the cold filtered oil being pumped through the brine cells in place of brine. This cooler is claimed to give a much higher unit transfer of heat than any other cooler, and a 12-cell unit has actually cooled as much as 1500 gallons of heavy oil and paraffin per hour, though it should be noted that the capacity depends so much on the nature of the oil and the content of paraffin or stearine which is to be extracted.

Glass Carboys have not sufficient strength in themselves to hold together without bursting when filled with a heavy liquid. For this reason a carboy is always provided with a hamper which, if of sound design, should follow the contour of the glass as closely as is possible. The pioneer manufacturers of carboys in this country are Messrs. R. and H. Leigh and Sons, Ltd., of Bolton, a firm which was the original patentee and inventor of the carboy hamper in 1876. The ordinary carboy makes a somewhat top-heavy package, and when used singly or in small numbers, some provision is necessary to prevent falling over. To meet this difficulty Messrs. Leigh and Sons originated the "Safety Crate" for the Railway Clearing House. This safety crate has been widely adopted and with certain adaptations, such as the "chinaman hat hoods," can be used for the transport of dangerous liquids, such as acetic anhydride. An accessory essential to the user of carboys is a carboy stand and tilter, which Messrs. Leigh and Sons supply either in stationary or portable types, in addition to the invaluable carboy barrow. Everything relating to carboys is supplied by this Bolton firm, even down to smaller gear such as carboy stoppers made of acid-resistant fire-clay.

The Eastman Chemical Co., of Rochester, N.Y., has issued a twelfth list of Eastman Organic Chemica... The list contains the names of over 1800 chemic... kept in stock, and more are continually being add... Three groups are available :—"Eastman's" chemic... of the highest purity obtainable, "Practical" che... cals of sufficient purity for laboratory work, a... "Technical" chemicals as obtained from large sc... manufacturers. In addition, many biological dy... vital stains and indicators are stocked. Data showi... the purity of the plant products are supplied ... request, and the company states that it would be gl... to hear of new organic compounds available f... purchase, or new sources of supply, and of chemica... required as it desires not only to prepare material... but to act as a medium for the mutual assistance ... organic chemists.

PRESENT-DAY PROBLEMS IN CROP PRODUCTION*

By SIR E. JOHN RUSSELL, F.R.S.

The visits of the British Association to Canada have hitherto very appropriately coincided with definite stages in the progress of agricultural science and practice. It was at the Montreal Meeting of 1884 that Lawes and Gilbert presented their well-known paper on the sources of the fertility of Manitoba soils which ended the first great period of the development of agricultural science. This period had lasted eighty years; it had been ushered in with the precise and scientific work of de Saussure published in 1804; its outstanding features had been the foundation of agricultural science by Boussingault in 1834, its enrichment by Liebig's brilliant essay of 1840, and its systematic development by Lawes and Gilbert at Rothamsted from 1843 onwards. The whole purpose of the scientific workers of the period was to feed the plant: in Gilbert's own words the message of the crops on the Rothamsted plots was, "If you won't feed us we won't grow." The success of the new science was remarkable; its great triumph was the discovery of artificial fertilisers and their introduction into farming practice, and the workers had the great joy of seeing the crop yields rise considerably as the direct and recognised result of their labours. The problems were largely chemical, and agricultural science was regarded as simply a branch of chemistry. Gilbert's paper in 1884 was read before the Chemical Section, and it presented soil fertility as essentially chemical; a fertile soil, he argued, is one containing much plant food, especially nitrogen; it is one "which has accumulated within it the residues of ages of natural vegetation, and it becomes infertile as this residue is exhausted." At the time of the Toronto Meeting in 1896 a new period had begun, quietly and unnoticed, but growth was so rapid that at the Winnipeg Meeting in 1909 the subject had grown right away from chemistry; it had become a definite subsection, and its importance was so widely recognised that a recommendation was passed asking the Council to set it up as a full section, which was subsequently done.

In this second period the purpose was not to feed the crop but to study it; to discover what factors are concerned in the growth of crops and how they operate. This period, which may be called the period of free exploration, since the workers were not usually tied down to any particular technical problem, began almost simultaneously in the United States, in France, and in Germany. As soon as agricultural science was studied in the United States it became evident that the cultivation of the soil was at least as important as the feeding of the crop. This fact had, of course, been fully recognised in the English experiments, but the English farmer was so skilled in cultivation that he could be taught but little by science. The early American work as developed by Kedzie at Michigan, King at Wisconsin, Hilgard, and Whitney, was largely physical, and it greatly widened the outlook of agricultural investigators, opening the way to the extensive physical and physico-chemical studies which have now become so characteristic a feature of American work. The French investigators, particularly Schloesing, Muntz, Berthelot, and Déhérain, and the brilliant Russian, Winogradsky, then in Paris, revealed a new world of soil micro-organisms, the wonder and mystery of which appealed to the imagination of the younger workers in a way that none of the older utilitarian work had done. The Germans methodically explored the fields thus opened up; Hellriegel and Wollny accumulated a mass of data as to plant growth and soil changes which still remains of value to the student. These pioneers were succeeded by a host of followers whom it would be impossible to enumerate at length, and from whom it would be invidious to select a few. Moreover, the chemists and physicists of the old school were no longer left in sole possession; van Bemmelen introduced the conception of colloids, and at a later date Mitscherlich, Baule, and others developed the idea of mathematical expressions for the data of agricultural science. Sachs and his pupils in Germany, Déhérain, Maquenne and Demoussy in France, joined up the new science of plant physiology with agricultural science. The plant breeder also came in; Gregor Mendel's work, after lying hidden for forty years, was revealed to the world by Bateson and was at once turned to agricultural use in England by one of Marshall Ward's pupils, R. H. Biffen; and in the United States by Webber and others. The selection method was developed to a high pitch of perfection in Canada by William Saunders, a revered leader in our science, whose dignified presence and kindly words of greeting remain as a vivid recollection of our visit fifteen years ago. His mantle has fallen on his son Charles, who has continued and developed the work.

The result of all this effort has been the accumulation of an enormous mass of information covering a very large part of the field with which agriculture has to deal. It has been essentially a pioneer period, with all the advantages of keen individual interest, controversy, sometimes even of excitement; but also with the disadvantages of a certain lack of perspective, failure to follow up important issues and some narrowness of outlook inevitable when a single individual is working alone at a great subject.

Generalisations that have emerged

But in spite of these drawbacks several important generalisations have emerged. One of the most pregnant in possibilities for the future is the recognition that the plant is a very plastic organisation and can be modified to a considerable extent within certain limits. Two methods are adopted: breeding, which may be on observational lines or on the Mendelian method of picking out the desired unit characters from plants in which they occur and assembling them in a new plant; and selection, in which a desirable plant is caused to produce seed from which stocks are multiplied. The scientific problems fall within the province of the science of genetics;

* Presidential Address before Section M (Agriculture) of the British Association, Toronto.

The practical significance of the work lies in the fact that it greatly simplifies the agricultural problem by providing plants more or less suitable to the existing natural conditions where otherwise the expert would have the difficult, if not impossible, task of making the conditions suit the available plants. The work has proved extraordinarily fruitful and has given astonishing results even in our own time. It has played no small part in the amazing development of wheat growing in Canada. When the British Association went to Winnipeg in 1909 we were all impressed by the fact that Canada had then passed the 160-million bushel mark in production, but who would have thought that within fourteen years the production would exceed 474 million bushels? Even in England, where wheat has been grown for 2000 years, and where farmers have a long traditional knowledge of the crop, the new varieties introduced by Biffen have increased the yields and the certainty of yields. The triumphs of Webber and others in the United States, of Nielson Ehle with cereals in Sweden, Jeffreys in standardising the quality of cotton in Egypt, the Howards in producing wheats for India, to mention only a few, are still fresh in our minds. In the first period in the development of agricultural science the honours in the matter of practical applications lay with the chemists for the artificial manures, but in the present period we must admit that they lie with the plant breeders and selectors who, indeed, are only on the threshold of what they may yet accomplish. And this great practical purpose of finding or producing varieties of crops specially suited to local conditions would be further advanced if the work were done in co-operation with plant physiologists who could precisely define the modifications required. Much saving of time and effort could be effected if it were possible to set up some international garden where small quantities of the plant breeders' productions could be grown, including those which each one has rejected as being unsuitable to his particular requirements. Many of these unwanted outcasts might prove of value in other conditions.

A second generalisation is that the soil is not a fixed, constant thing, but is pulsating with change. It contains a great population of micro-organisms which, among other activities, decompose the dead plant residues, producing nitrates, humic and other substances of great importance in crop production. But the numbers of these organisms fluctuate continually; and the bacteria at least change hourly; the nitrates suffer equally rapid changes in amount. Even the mineral part of the soil is not constant in composition. Modern research work shows that many of the properties determining fertility in soils are due to the soil colloids, and some of the most important are attributable to calcium complexes. These are unstable and are affected by the soil water. If the water is free from salts but contains carbon dioxide, the calcium may be replaced by hydrogen, and an acid soil results; if the water contains sodium chloride, the calcium is replaceable by sodium and the resulting complex may readily give rise to an alkali soil. So far as is known, the changes are governed by the ordinary stoichiometric laws, the equilibrium following the usual course expected when a colloid is concerned. But the important fact emerges that any soil not well supplied with calcium contains within itself the possibility of becoming acid and therefore infertile, or alkaline and probably sterile, according to the nature of the soil water soaking through it. The various biological and chemical changes tend to alter the composition of the soil solution. Apparently, however, the colloids have a steadying or "buffering" effect, reducing the degree of acidity caused by the production of acids and absorbing or precipitating various ions that might otherwise cause disturbances.

TABLE I

Soils of similar types as regards mechanical analysis, but varying greatly in fertility by reason of climatic differences

	Rich in finer fractions				Rich in coarser fractions	
	Waste land very difficult of cultivation	Fertile soil, millet & cotton	Poor farm land difficult to cultivate	Good prairie soil, Wheat	Waste land, Norfolk	Market garden, Anglesey
	Lias clay, Oxfordshire	Sudan	Weald clay, Kent	Brandon	22 in. rain	35 in. rain
Coarse sand, 2·0 to 0·2 mm.	0·7	7·6*	1·5	2·5	62·4	93·7
Fine sand, 0·2 to 0·04 mm.	2·0	20·9	11·0	15·4	25·7	2·8
Silt, 0·04 to 0·01 mm.	6·4	12·6 (silt and fine silt together)	19·6	17·7	0·2	0·5
Fine silt, 0·01 to 0·002 mm.	22·0		26·8	16·1	1·8	0·4
Clay (below 0·002 mm.)	41·0	55·9	22·1	29·2	0·6	Nil

* Mainly black nodules of calcium carbonate

A third important generalisation that has emerged is that the relations of the plant and the soil are not rigidly fixed but are capable of considerable variation, being profoundly influenced by a third factor, the climate. A soil moderately fertile in one set of conditions may be relatively unproductive in another. This happens repeatedly with soils containing much clay or much coarse sand. In Table I are given the mechanical analyses of two soils, one of which, the Lias clay from England, is quite unworkable and remains derelict under our conditions of cool temperature and moderate but frequent rainfall, by reason of its high content of clay and fine silt; while the other, which contains even more clay, is capable of carrying good crops of grain and cotton under the hot dry conditions

of the Sudan. The Western prairie soil is of similar physical type to that of the English Weald soil, but while the prairie soil under its climatic conditions of warm dry summer and cold dry winter is, and is likely to remain, a fertile wheat producer, the Weald soil, under the wetter conditions of England, is less fertile. In hot dry conditions the clay is no disadvantage and may even be an advantage, but in wet conditions it becomes a serious drawback; indeed, it might be possible to find some mathematical relationship between rainfall and degree of objectionableness in clay.

It appears then that if a fertile soil were carried from one country to another its productive power would not necessarily be carried with it. Its fertility is, to a considerable extent, dependent on the fact that it fits in with the climatic factors in producing conditions favourable to good growth of desirable crops.

Complexity of the Problem: *Methods of Attack*

The agricultural investigator is thus confronted with three closely interlocking agencies—the plant, the climate, and the soil—each of which is variable within certain limits, and each playing a large part in the crop production which it is his business to study.

Confronted with a problem of this degree of complexity there are two methods of procedure: the empirical method of field observations and experiments, in which there is no pretence of great refinement and no expectation that the same result will ever be obtained twice, it being sufficient if over an average of numerous trials a result is obtained more often than would be expected from the laws of chance; and the scientific method, in which the factors are carefully analysed and their effects studied quantitatively; a synthesis is then attempted, and efforts are made to reconstruct the whole chain of processes and results. The scientific method is, of course, the one to which we are naturally attracted. But common truthfulness compels one to admit that up to the present the greatest advances in the actual production of crops have been effected by the empirical method, and not infrequently by men who are really artists rather than men of science, in that they are guided by some intuitive process which they cannot explain, and that they have the vision of the result before they obtain it, which the scientific man commonly has not.

The best hope for the future lies in the combination of the empirical and the scientific methods. This is steadily being accomplished by the recent strong infusion of science into the art of field experimentation, which has much enhanced the value of the field work and the trustworthiness of its results. Modern methods of replication, such as have been worked out at Rothamsted, and in the United States by Harris of the Carnegie Trust (Cold Spring Harbour), Kiesselbach in Nebraska, Myers and Love of Cornell, and others, constitute a marked improvement in plot technique. And the figures themselves, besides being more accurate, can be made to yield more information than was formerly the case.

Great advances have been made in the methods of analysing the results. The figures are never the same in any two seasons, since the climatic conditions profoundly affect the yields. A few men, like J. H. Gilbert, have the faculty of extracting a great deal of information from a vast table of figures, but in the main even the trained scientific worker can make very little of them. The reason is that he has been brought up to deal with cases where only one factor is varying, while the growth of plants involves the interaction of three variable factors: the plant, the soil, and the climate. It is impossible to apply in the field the ordinary methods of the scientific investigator where single factors alone are studied; very different methods are needed, adapted to the case where several factors vary simultaneously.

Fortunately for agricultural science, statisticians have in recent years worked out methods of this kind, and these are being modified and developed by R. A. Fisher and Miss Mackenzie for application to the Rothamsted field data. It so happens that this material is very suitable for the purpose, since a large number of the field experiments have been repeated every year for seventy or eighty years on the same crop, and on the same piece of land, using the same methods; the field workers also remain the same for many years, the changes being rare and without break in continuity. Although the statistical investigation is only recently begun, mathematical expression has already been given to the relationship between rainfall and yield of wheat and barley under different fertiliser treatments, and precision has been given to some of the ideas that have hitherto been only general impressions. If on an average of years a farmer is liable to a certain distribution of rainfall, it is becoming possible to advise as to fertiliser treatment which enables the plant to make the best of this rainfall.

Unfortunately, few other Experimental Stations possess such complete masses of data as Rothamsted. Methods are now being devised, however, both by Fisher and by the able English investigator who modestly conceals his identity under the pseudonym "Student," for the study of smaller numbers of data, and it is hoped that these or others equally effective will be applied to the results of field experiments accumulated at various Experimental Stations throughout the world. A massed attack by a competent band of statisticians on the whole of the data of the best Experimental Stations, dealing with yields of crops under different conditions of nutrient supply, temperature, rainfall and other factors that go to make up the aggregate called season, would yield information of extraordinary value.

Investigations of this kind, however, are necessarily slow, and they do not themselves afford complete information; their value lies in the fact that they reduce a very complex problem to a set of single-factor problems of the type with which the scientific investigator is already familiar. In the meantime, while this work is proceeding, much is being done by observational methods. At Rothamsted the field plots are under continual observation by a group of three workers, a physiologist, an ecologist, and an agriculturist, who study such factors as rate or habit of

growth, earliness of starting or maturing, degree of resistance to insect or fungus attack; their observations are fully recorded and brought before the chemical, physical and botanical departments at regular and frequent intervals. Certain of the experiments are repeated at other centres on closely similar lines for purposes of comparison. In consequence our old field plots, which have been studied for the past eighty years by Lawes, Gilbert, Warington, and Hall, and might have been supposed to have no further tales to tell, are found to be still yielding results of great interest in agricultural science and practice.

The Results Obtained: Alterations in the Plant

We shall begin with the results obtained by effecting alterations in the plant. Reference has already been made to the changes brought about by the plant breeder, and we need not stop to argue whether the great improvements in crops made in pre-Mendelian days by the Suttons and Findlay in potatoes, by Chevalier in barley, by the Gartons in oats, Vilmorin in sugar beet, and others, should be labelled empirical or scientific. There are certain other changes in plants, however, of a purely temporary nature, which have been induced by changes in conditions. It is a commonplace among farmers that certain soil conditions influence not only the yield but also the quality of crops. The leaf and root are more easily affected than the seed. The case of mangolds has been investigated at Rothamsted; the sugar content of the root, an important factor in determining feeding value, was increased by increasing the supply of potassium to the crop. Middleton at Cockle Park showed that grass increased in feeding value—quite apart from any increase in quantity—when treated with phosphates. Potatoes are considerably influenced by manuring; increasing the supply of potassium influences the composition of the tubers and also that much more impalpable quality—the cook's estimate of the value of the potato; while we have found at Rothamsted that a high-class cook discriminated between potatoes fertilised with sulphate of potash and those fertilised with muriate of potash, giving preference to the former.

Grain is more difficult to alter by changes in environmental conditions; indeed, it appears that the plant tends to produce seed of substantially the same composition whatever its treatment—with the important exception of variation in moisture supply. Mr. Shutt has explored the possibilities of altering the character of the wheat grain by varying the soil conditions, and finds that increases in soil moisture decrease the nitrogen in the grain. Similar results have been obtained in the United States.

On the other hand, in England the reverse seems to hold, at any rate for barley. This crop is being fully investigated at the present time under the Research Scheme of the Institute of Brewing, because of its importance in the preparation of what is still Britain's national beverage. Increased moisture supply increases the percentage of nitrogen in the grain, and so also does increased nitrogen supply, though to a much less extent; on the other hand, both potassic and phosphatic fertilisers may decrease the percentage of nitrogen, though they do not always do so; the laws regulating their action are unknown to us.

The practical importance of these problems of regulating the composition of the plant lies in the fact that the farmer can control his fertiliser supply, and also to some extent his moisture supply, so that it lies within his power to effect some change should he wish to do so.

The following are the nitrogen contents and the valuations of barley grown in the same season from the same lot of seed on farms only a few miles apart:—

Effect of Moisture

	Drier soil	Moist land
Nitrogen per cent. in grain	1·44	1·80
Valuation per quarter of 448 lb.	52s. 5d.	41s. 6d.

Effect of Nutrients

	No nitrogenous manure	Nitrogenous manure
Nitrogen per cent. in grain	1·379	1·464
Valuation per quarter of 448 lb.	53s.	52s.

At present we know but little about the matter, and we are not in a position to advise the farmer as to how he may use these facts to the full advantage. The complete study of the problem necessitates the co-operation of a plant physiologist.

There is another direction also in which alterations in the plant would be of great value if only we knew with certainty how to bring them about.

In agricultural science one sometimes thinks only of the crop and the factors that affect its growth. But in agricultural practice there is often another partner in the concern: a pest or parasite causing disease. The amount of damage done by pests and diseases to agricultural crops is astounding; in Britain it is probably at least 10 per cent. of the total value of the crops, and the loss is probably some £12,000,000 sterling per annum; in some countries it is considerably more. Indeed, the number of insect pests and of harmful fungi and bacteria that skilled entomologists and mycologists have found in our fields might almost lead us to despair of ever raising a single crop, but fortunately the young plant, like the human child, grows up in spite of the vast number of possible deaths. The saving fact seems to be that the pest does harm only when three sets of conditions happen to occur together: the pest must be present in the attacking state; the plant must be in a sufficiently receptive state; and the conditions must be favourable to the development of the pest. It is because this favourable conjunction of conditions comes but rarely that crops manage to survive. And this gives us the key to control if only we knew how to use it. Complete control of any of these three conditions would end all plant diseases. Unfortunately, control is never complete even in glasshouse culture, still less out of doors. But even partial control would be very helpful. All these pests go through life cycles, which are being studied in great detail all over the world,

and especially in the United States. Somewhere there occurs a stage which is weaker or more easily controlled than others, and the pest would become harmless if the chain could be broken here or if the cycle could be sufficiently retarded to give the plant a chance of passing the susceptible stage before it is attacked.

The plants themselves, as we have just seen, are in some degree under control, and if they could be pushed through the susceptible stages before the pest was ready they would escape attack. Barley in England is sometimes considerably injured by the gout fly (*Chlorops tæniopus*). The larvæ emerge in spring from the eggs laid on the leaves and invariably crawl downwards, entering the young ear if, as usually happens, it still remains ensheathed in leaves. J. G. H. Frew, at Rothamsted, has shown that early sowing and suitable manuring cause the ear to grow quickly above the track of the larvæ, and thus to escape injury. E. A. Andrews, in India, has found that tea bushes well supplied with potassic fertiliser escape attack from the mosquito bug (*Helopeltis*) for the rest of the season, apparently because bushes so treated become unsuitable as food to the pest. And further, the conditions are alterable. H. H. King, in the Sudan, has effected some degree of control of the cotton thrips (*Heliothrips indicus*) by giving the plant protection against the drying North wind and so maintaining a rather more humid atmosphere—a condition in which the plant flourishes more than the pest. Tomatoes in England suffered greatly from *Verticillium* wilt till it was found that a small alteration of temperature threw the attack out of joint. They are also much affected by stripe disease (*B. lathyri*), but they become more resistant when the supply of potash is increased relative to the nitrogen. It has recently been maintained, though the proof is not yet sufficient, that an altered method of cultivating wheat in England will afford a good protection against bunt. These cultural methods of dealing with plant diseases and pests offer great possibilities, and a close study jointly by plant physiologists and pathologists of the responses of the plant to its surroundings, and the relationships between the physiological conditions of the plant and the attack of its various parasites, would undoubtedly yield results of great value for the control of plant diseases. Again, however, the plant breeder can save a world of trouble by producing a variety resistant to the disease; or there may fortunately be found an immune plant from which stocks can be had, as in the case of the potatoes found by Mr. Gough to be immune to the terrible wart disease.

Control of Environmental Factors

It thus appears that, if only plant breeders and plant physiologists could learn to alter existing plants or to build up new plants in such a way that they should be well adapted to existing soil and climate conditions, and not adapted to receive disease organisms at the time the organisms are ready to come—if only they could do this all agricultural land would become fertile and plant diseases and pests would become ineffective: at any rate until the pests adapted themselves to the new plants. Although no one can set limits to the possibilities of plant breeding and plant physiology, we cannot assume that we are anywhere near this desirable achievement or that we are likely to be in our time. There will always remain the necessity for altering the environmental conditions to bring them closer to the optimum conditions for the growth of the plant. No attempt is yet made in the field to control two of the most important of the factors: the light and the temperature, though it is being tried experimentally. There is a great field for future workers here; at present plants utilise only a fraction of the radiant energy they receive. At Rothamsted attempts have been made by F. G. Gregory to measure this fraction; the difficulties are considerable, but the evidence shows that our most efficient plants lag far behind our worst motor-cars when regarded as energy transformers for human purposes. One hundred years ago the efficiency of an engine as transformer of energy was about 2 per cent.; now, as a result of scientific developments, it is more than 30 per cent. To-day the efficiency of the best field crops in England as transformers of the sun's energy is about 1 per cent.*; can we hope for a similar development in the next hundred years? If such an increase could be obtained an ordinary crop of wheat would be about 400 bushels per acre, and farmers would feel sorry for themselves if they obtained only 200 bushels. But we are only at the beginning of the subject. Increases in plant growth amounting to some 20 or 25 per cent. have been obtained by V. H. Blackman in England under the influence of the high-tension electric discharge, which presumably acts by increasing in some way the efficiency of the plant as an energy transformer. Possibly other ways could be found. It needs only a small change in efficiency to produce a large increase in yield. Much could be learned from a study of the mass of data which could be accumulated if agricultural investigators would express their results in energy units as well as in crop yields as at present.

Interesting results may be expected from the attempts now being made in glasshouse culture both in Germany and at Cheshunt to increase the rate of plant growth by increasing the concentration of the carbon dioxide in the atmosphere.

Control of the Soil Factors

The soil factors lend themselves more readily to control and much has been already achieved. Water supply was one of the first to be dealt with. Civilisation arose in the dry regions of the earth, and as far back as 5,000 years ago irrigation was so advanced as a practical method that it came into the ordinances drawn up by the great Babylonian king Hammurabi. The chief problems at the present time are to discover effective means of economising water and to ascertain, and if possible control, the relationships between the soil, the

* The remaining energy being largely used up in transpiration. This figure refers to the total radiation received by the leaf, and not to the fraction received by the chloroplast surface. For this latter the value is much higher.

water, and the dissolved substances in the water. Economical use of water is necessary because it allows larger areas to be irrigated, and because water beyond a certain amount injures the soil and asphyxiates the plant roots. This part of the problem is largely one of engineering and police control. The more serious problem, perhaps the most serious confronting agricultural science to-day, is that presented by the soluble matter in the water and the soil. The terrible spectre of alkali looms ahead of every irrigation project; it may be kept under control for a longer or shorter time or it may completely wreck the scheme. Instances could be multiplied of schemes started with great expectations of results yet yielding only disappointment and loss. A volume could be filled with the tragedies of the alkali problem. Neutral salts, particularly sodium sulphate, are not harmful to plants unless their concentration exceeds a certain critical value; indeed, some of the heavy soils in dry countries, as in Egypt and the Sudan, become unworkable if washed with pure water; they remain flocculated only because some soluble salts are present. Chlorides beyond a critical concentration are more harmful to the plant, but sodium carbonate is deadly, and there is no certain way at present of overcoming its effects.

The empirical method has apparently gone as far as it can, and nothing more can be expected until some fresh opening is discovered by scientific workers.

Almost equally important is the more efficient utilisation of water in districts where the rainfall is sufficiently high to obviate the need for irrigation, but insufficient to allow of any wastage of water. The practical work of the Utah agriculturists as exemplified by Widstoe, and the laboratory results of Keen at Rothamsted, all indicate that something can be done. It is legitimate to hope that the next great advance will come from Canada, where in the West there are admirable opportunities for studying the problem.

Inseparably bound up with water supply are the questions of cultivation and of drainage, which affect not only the water but the air supply to the roots. This former subject is now attracting considerable attention: the great need is to discover means for expressing cultivation in exact physical and engineering units. The measurements of Keen and Haines at Rothamsted, and the chemical work of A. F. Joseph, N. Comber and others on clay, and of Odén, Page, and others on humus, indicate the possibility of finding exact expressions and of effecting co-operation with the workers in the new fields of agricultural engineering.

Another soil factor which readily lends itself to some degree of control is the amount of plant nutrients present. The possibility of increasing this by means of manure has been so frequently explored in field trials that it has sometimes been regarded as almost a completed story; indeed, Rothamsted tradition affirms that Lawes himself once gave orders to have the Broadbalk field experiments discontinued because they had nothing further to tell; it was only the earnest persuasion of Gilbert that caused him to countermand the order. So far from the subject being exhausted, it still bristles with problems. The new nitrogenous fertilisers, resulting from war-time activities in nitrogen fixation; the need for reducing the cost of superphosphate; the change in character of basic slag; and the Alsatian development in potash production are producing changes in the fertiliser industry the full effects of which are not easy to foresee. Economic pressure is driving the farmer to derive the maximum benefit from his expenditure on fertilisers, lime, farmyard manure and other ameliorating agents, and is compelling a more careful study of possibilities hitherto disregarded, such as the use of magnesium salts, silicates, and sulphur as fertilisers, and, above all, a much more precise diagnosis of soil deficiencies than was thought necessary in pre-war days.

But there are more fundamental problems awaiting solution. It is by no means certain that we know even yet all the plant nutrients. The list compiled by Sachs many years ago includes all needed in relatively large amounts, but Gabriel Bertrand has shown that it is not complete and that certain substances—he studied especially manganese— are essential, although only in very small amounts. Miss Katherine Warington, working with Dr. Brenchley at Rothamsted, has shown that leguminous plants fail to develop in the so-called complete culture solution unless a trace of boric acid is added. Mazé has indicated other elements needed in small amounts.

Another problem needing elucidation is the relationship between the quantity of nutrients supplied and the amount of dry matter produced. Is dry matter production simply proportional to nutrient supply, as Liebig argued, with the tailing off beyond a certain point, as demonstrated by Lawes and Gilbert, or is it always less than this, as indicated by Mitscherlich's logarithmic curve, or is the relationship expressed by one of the more complex sigmoid curves as there is some reason to suppose? We do not know; and the problem is by no means simple, yet it governs the "diminishing returns" about which farmers now hear so much. Again, very little is known of the relationship between nutrition and period of growth. One and the same quantity of a nitrogenous fertiliser, for example, may have very different effects on the plant according as it is given early or late in life; not only is there a difference in quantity of growth, but also in the character of the growth. Late dressings cause the characteristic dark-green colour to appear late in the season, and thus affect the liability to fungoid diseases; they increase the percentage of nitrogen in the grain and they may give larger increases of crop than early dressings.

Investigations are needed to find the best methods of increasing the supply of organic matter in the soil and its value for the different crops in the rotation.

All these problems will sooner or later find some solution. But there remains a greater problem of more importance than any of them: the linking-up of plant nutrition studies with those of the soil solution. As our cousins in the United States were the first to emphasise, the fundamental agent

in the nutrition of the plant is the soil solution, and they have made a remarkable series of investigations into what appeared at one time a hopeless proposition—the physico-chemical interactions between the soil and the soil water. Whitney and Cameron began the work, and it has gone on with much controversy—as important scientific investigations always do—and it is now being attacked with much vigour by some of the younger scientific workers, particularly in the Californian school; Burd, Hoagland, Kelley, Lipman, Stewart, Sharp, and others. There is also some valuable work by Gola and other Italians. The natural soil solution is not always the best for the growth of plants. It is reasonable to suppose that the most efficient method of using fertiliers would be for making up the soil solution to the optimum composition and concentration for each stage of the growth of the crop. Unfortunately, this cannot yet be done. The added fertiliser does not simply increase the concentration of the soil solution to the precise extent that might be expected; there are interactions, absorptions, and base exchanges of the kind studied first by Way, much later by van Bemmelen and by Gedroiz, and more recently by Hissink and by Wiegner. Further, the plant relationships are not constant; there is apparently—though this is not certain—more response to certain nutrients at one time of its life than at another. A great advance in crop production may be expected when the soil chemists have discovered the laws governing the soil solution, when the plant physiologists can give definite expression to the plant's response to nutrients, and when someone is able to put these results together and show how to alter the soil solution so that it may produce the maximum effect on the plant at the particular time. The new soil chemistry will yet have its triumphs.

The Soil Micro-organisms: Can they be Controlled?

It is now more than forty years since the discovery of the great importance of micro-organisms in determining soil fertility. Practical applications necessarily lag far behind; but already three have been made each of which opens out great possibilities for the future. The long-standing problem of inoculation of leguminous crops with their appropriate organisms has already been solved in one or two of its simple cases, chiefly lucerne on new land, and the new process has helped in the remarkable extension of the lucerne crop in the United States and in Denmark. We believe at Rothamsted that the more difficult English problem is now solved also. Interesting possibilities are opened up by the observation that a preliminary crop of Bokhara clover seems to facilitate the growth of the lucerne.

The organisms effecting decomposition are now coming under control, and are being made to convert straw into farmyard manure (or a material very much like it) without the use of a single farm animal. The process was worked out at Rothamsted, and is being developed by the Adco Syndicate, who are now operating it on a large scale and are already successfully converting some thousands of tons of straw annually into good manure.

The third direction in which control of the soil organisms is being attempted is by partial sterilisation. This process is much used in the glasshouse industry in England, and it has led to considerable increases in crop yields. The older method was to use heat as the partial sterilising agent, and this still remains the most effective, but owing to its costliness efforts have been made to replace it by chemicals. Considerable success has been attained; we have now found a number of substances which seem promising. Some of these are by-products of coal industries; others, such as chlor- and nitro-derivatives of benzene or cresol, are producible as crude intermediates in the dye industry.

The Need for Fuller Co-operation

Looking back over the list of problems it will be seen that they are all too complex to be completely solved by any single worker. Problems of crop production need the co-operation of agriculturists, plant physiologists, soil investigators, and statisticians. Even plant breeding necessitates the help of a physiologist who can specify just what the breeder should aim at producing. And this gives the key-note to the period of agricultural science on which we have now entered—it is becoming more and more a period of co-operation between men viewing the problem from different points of view. Good individual work will, of course, always continue to be done, but the future will undoubtedly see a great expansion of team work such as has already led to important results in medical research, and such as we know from our experience at Rothamsted is capable of giving admirable results in agricultural science.

The team work should not be confined to individuals working at the same institution. The world would gain greatly if co-operation such as now exists between the Imperial College Botany School and Rothamsted could be effected between other great institutions devoted to agricultural science in the various countries of the world. To take only one illustration: how much could be accomplished in the study of the very difficult alkali problem if it were possible to organise a team representing such great agricultural stations as, for instance, California and Utah, the Departments of Agriculture of India and other of the great Dominions affected, Rothamsted, Hissink's school, with power to lay down experiments anywhere and money to carry them out. And if extended co-operation of this kind should prove impossible of attainment, much could be done by fostering co-operation between the Agricultural Institutions of the Empire. There are certain great problems which are common to large parts of the Empire where the experience of one part would be of great value to the rest. The institutions in Britain, for example, have experience of problems connected with land long since settled and brought into cultivation, where men must produce 40 or more bushels per acre of wheat and 6 to 10 tons per acre of potatoes to make these crops pay, and where animal husbandry must be run on sound and economic lines. Canada has an unrivalled experience with wheat, and

in the Western provinces has a magnificent chance for studying one of the most important problems of the day—the water supply to the crop. Australia, New Zealand, South Africa, East, West, and Tropical Africa, India, the West Indies—to mention only a few in the great family that forms the British Empire—all have their special lines in agricultural development; each has some achievement that can be shown with pride and in the certainty that its study will benefit others. The Empire has already its Conference of Premiers, why should it not have its conference for agricultural science and practice?

With fuller co-operation both of men and of institutions we could do much to overcome the present difficulty in regard to utilising the information we already possess. In the last thirty years an immense stock of knowledge has been obtained as to soils and crops—knowledge that ought to be of supreme value in interpreting the facts of Nature as shown in the field. It is stored in great numbers of volumes which line the shelves of our libraries, and there much of it rests undisturbed in dignified oblivion. In the main it consists of single threads followed out more or less carefully; only rarely does some more gifted worker show something of the great pattern which the threads compose. But even the most gifted can see but little of the design; the best hope of seeing more is to induce people to work in groups of two or three, each trained in a different school and therefore looking at the problem from a different point; each seeing something hidden from the rest. Unlike art, science lends itself to this kind of team work; art is purely an individual interpretation of Nature while science aims at a faithful description of Nature, all humanistic interpretation being eliminated. There is certainly sufficient good will among the leaders of agricultural science to justify the hope of co-operation; there are probably in existence foundations which would furnish the financial aid.

And that leads to my last point. What is the purpose of it all? Team work, co-operation, the great expenditure of time and money now being incurred in agricultural science and experiment—these are justified only if the end is worthy of the effort. The nineteenth century took the view that agricultural science was justified only in so far as it was useful. That view we now believe to be too narrow. The practical purpose is of course essential; the station must help the farmer in his daily difficulties—which again necessitates co-operation, this time between the practical grower and the scientific worker. But history has shown that institutions and investigators that tie themselves down to purely practical problems do not get very far; all experience proves that the safest way of making advances, even for purely practical purposes, is to leave the investigator unfettered. Our declared aim at Rothamsted is "to discover the principles underlying the great facts of agriculture, and to put the knowledge thus gained into a form in which it can be used by teachers, experts, and farmers for the upraising of country life and the improvement of the standard of farming."

This wider purpose gives the investigator full latitude, and it justifies an investigation whether the results will be immediately useful or not—so long as they are trustworthy. For the upraising of country life necessitates a higher standard of education for the countryman; and education based on the wonderful book of Nature which lies open for all to read if they but could. How many farmers know anything about the remarkable structure of the soil they till, of its fascinating history, of the teeming population of living organisms that dwell in its dark recesses; of the wonderful wheel of life in which the plant takes up simple substances and in some mysterious way fashions them into foods for men and animals and packs them with energy drawn out of the sunlight—energy which enables us to move and work, to drive engines, motor-cars, and all the other complex agencies of modern civilisation? No one knows much of these things; but if we knew more, and could tell it as it deserves to be told, we should have a story that would make the wildest romance of human imagination seem dull by comparison, and would dispel for ever the illusion that the country is a dull place to live in. Agricultural science must be judged not only by its material achievements, but also by its success in revealing to the countryman something of the wonder and the mystery of the great open spaces in which he dwells.

THE TORONTO MEETING OF THE BRITISH ASSOCIATION

August 6—13, 1924

By unanimous consent the British Association's meeting has been this year a brilliant and stimulating function. No one who has been fortunate enough to attend the Conference can doubt its vitality or the importance of its task in educating the public as to the real meaning and value of science. The Canadian public, moreover, was only too ready to appreciate the benefits which have accrued to humanity, and to Canada in particular, from the disinterested labours of many generations of scientists. The twentieth century could not have been "Canada's century," without the numerous discoveries which have enabled its vast resources of water power and mineral wealth to be profitably utilised. Hence the very hearty welcome which British Scientists have received throughout their journey.

This is the fourth time the British Association has met in Canada, the last occasion having been in Winnipeg in 1909.

Over 500 members crossed the Atlantic, the Cunard liner *Caronia* alone carrying a party of about 250—and, together with the Canadian and American contingent, the number of those attending the Conference exceeded two thousand. It is greatly to the credit of the Local Organising Committee, under the chairmanship of Prof. J. C. McLennan, O.B.E., F.R.S., that all arrangements in connexion with the location of such an enormous number of visitors have proceeded smoothly. Many of the overseas visitors were privately entertained, whilst others were housed at residential colleges.

The extensive grounds and buildings of the University of Toronto which, according to the cautious *Baedeker*, are "perhaps the finest *ensemble* of college architecture in the Western hemisphere," formed a delightful centre for the activities of the Association. At this remarkable gathering not only England and Canada, but many other parts of the British Empire, including India and South Africa, were represented. There was, in addition, what amounted to an invasion of U.S. scientists; in the chemical and physiological sections one noticed Prof. E. W. Washburn, Prof. J. H. Bancroft (Cornell Univ.), Profs. Kendell, Shearman and Eddy (Columbia Univ.), Dr. van Slyke (Rockefeller Inst.), Prof. Underhill (Yale Univ.), Prof. Bloor (Rochester Univ.), Dr. Voegtlin, Dr. Clowes, and many other eminent chemists and bio-chemists.

The cosmopolitan appearance of the meeting was further emphasized by the presence of a large number of foreign mathematicians, delegates to the International Mathematical Congress, which held its annual session about the same time (August 11 to 16) in Toronto.

The papers presented to the different sections of the Association were, as usual, numerous and varied. Those of special interest to our readers were reported elsewhere.

Sir Robert Robertson's presidential address to Section B—illustrated with slides of eminent British scientists who had been in the service of the Government—was a masterly exposition of the importance of chemistry to the modern State, and attracted a large audience. The papers and discussion on the Canadian electro-chemical industries were suggestive.

An important point brought out was that, unlike the home country, Canada possesses an excess of harnessed power which frequently runs to waste; consequently, in certain circumstances it has even been found commercially advisable to produce steam by means of electrical energy. The speculative point was raised as to whether at some future date it may not be possible to store the excess of available power as chemical energy—*e.g.*, by the electrolysis of salt, or water, and the subsequent utilisation of the resulting elements as sources of heat.

Of equally great interest were the joint discussions —with Section C (Geology) on powdered fuels, with Section A (Physics) on Crystal Structure and Colloids, and with Section I (Physiology) on Vitamines. If one may venture a criticism, it is this—had the papers been printed and circulated in advance, more time could have been made available for these discussions which, after all, are among the most important features of a meeting of this type.

Owing to the absence of Dr. G. S. Hume the paper on liquid fuels was not read, but an important discussion took place on the use of pulverised coal in metallurgical plants and as locomotive fuel.

The X-ray analysis of crystals was dealt with by Sir Wm. Bragg in a characteristically lucid manner. Colloids and theories appertaining thereto formed the subject of an animated debate, Profs. McBain and Donnan expressing divergent views concerning the existence and function of the much-disputed Helmholtz double-layer.

The "Citizens' lectures" were an unqualified success. The immense Convocation Hall of the University was filled to overflowing, even on the occasion of a lecture on such an abstruse subject as "Einstein's theory of Relativity," by Prof. Eddington.

Of hardly less value than the theoretical discussions were the numerous excursions and visits to works and laboratories. Members of the Chemical Section had the opportunity of visiting paper and pulp factories at Ottawa, the plant of the International Nickel Co. at Port Colborne, the Research Laboratories of the Hydro-Electric Commission, and many other important manufacturing establishments. Those whose time permitted them to undertake the Western Excursion across the Continent were able to make an even more intimate acquaintance with the many important branches of the Canadian chemical and mining industries, including the famous mining areas of Cobalt, Porcupine and Sudbury.

Naturally, there was no lack of social amenities to lighten the austerity of scientific labours. The Canadian people have fully justified their fame for hospitality. In every city through which the overseas members passed they were lavishly entertained. Garden parties and receptions were plentiful and, in spite of the enforced "dryness," the spirit of joviality throve on lemonade and ice-cream. On one occasion youthful white-bearded professors were seen dancing the polka and mazurka to the rhythm of a syncopated tune.

An excursion to Niagara Falls terminated the local programme of this most successful meeting, and two train-loads of scientists have moved westwards across Canada on a tour which will last about three weeks, and will include visits to Winnipeg, Saskatoon, Edmonton, Vancouver, Victoria and many other points of interest.

NICKEL PRODUCTION IN CANADA

The revised statistics of nickel in Canada for the year 1923 show that there has been a marked revival in production. The output last year was 62,057,835 lb., contained in cupronickel matte, as compared with 17,355,056 in the previous year, whilst the nickel contents resulting from the treatment of silver-cobalt ores increased in 1923 to 396,007 lb. from 242,067 lb. in 1922. The total computed value of the nickel production was $18,332,077, based on a value of 29·35 cents. a pound. The total amount of ore mined by the three companies Mond, British America and International, was 1,187,355 tons. The output of nickel for the three months of this year shows an increase of 74 per cent., compared with the corresponding period of the past calendar year. The precious metals recovered during the first quarter of 1924, by the nickel refineries, were as follows:—gold $4988, silver $10,266, platinum $50,901 (495 oz.), palladium $42,586 (638 oz.), rhodium $20,476 (276 oz.), ruthenium $12,820 (105 oz.).

FORTHCOMING EVENTS

Sept. 8 to 11. INSTITUTE OF METALS. Annual Autumn Meeting, to be opened at the Institution of Mechanical Engineers, when W. M. Corse, S.B., will deliver the third annual Autumn Lecture. On September 9 the morning will be devoted to reading and discussion of papers, followed by luncheon at the Connaught Rooms, Kingsway, the afternoon to be spent at Wembley.

The following papers will be read:—"A Method for Measuring Internal Stress in Brass Tubes," by R. J. Anderson and E. G. Fahlman; "The Application of the Ideal Solubility Curve to the Interpretation of Equilibrium Diagrams in Metal Systems," by D. H. Andrews and Prof. J. Johnston; "Seventh Report of the Corrosion Research Committee of the Institute of Metals," by G. D. Bengough and R. May; "Comparative Results on Copper-Silicon-Aluminium and Other Aluminium Alloys as Obtained on Separately Cast Specimens and Specimens cut from a Crankcase Casting," by E. H. Dix and A. J. Lyon; "The Determination of Sodium in Aluminium," by D. M. Fairlie and G. B. Brook; "The Extrusion of Brass Rod by the Inverted Process," by R. Genders; "Investigation of the Effects of Impurities on Copper. Part II—The Effect of Iron on Copper," by D. Hanson and Grace W. Ford; "The Relationship Between Tensile Strength, Temperature and Cold-Work in Some Pure Metals and Single Solid Solutions," by D. H. Ingall; "On the Effect of Progressive Cold-Rolling on the Brinell Hardness of Copper," by H. Moore; "Experiments on the Working of Nickel for Coinage," by Sir T. K. Rose and J. H. Watson; "Some Experiments on the Effect of Casting Temperature and Heat-Treatment on the Physical Properties of a High-Tin Bronze," by F. W. Rowe; "Some Experiments on the Influence of Casting Temperature and Mass on the Physical Properties of Admiralty Gun-Metal," by F. W. Rowe; "Studies in the Aluminium-Zinc System," by T. Tanabe; "Metal Spraying and Sprayed Metal," by T. H. Turner and W. E. Ballard.

Sept. 15. BRITISH EMPIRE EXHIBITION. Conferences of Engineering Societies, to be held in Conference Hall No. 4, at 10.30 a.m. Short papers on various Engineering Subjects will be read and discussed.

Sept. 18 and 19. THE CERAMIC SOCIETY, Refractory Materials Section Meeting, in Conference Hall No. 4, British Empire Exhibition, Wembley.

The following papers will be read:—"A Comparison of Gas and Coke Fired Drying Stoves, together with a Description of the Construction and Operation of the Hüttenes Coke-Fired Air-Blown Furnace," by T. W. Barley; "Some Properties of Clay Silimanite Mixtures," by J. W. Cobb and H. S. Houldsworth; "The Influence of Exposure on the Chemical and Physical Properties of Certain Fireclays," by W. Hugill and W. J. Rees; "On the Action of Heat on Kaolinite and Kolinitic Clays" (Communicated Paper), by W. Vernadsky; "Alumina-Silica Minerals in Firebricks," by W. J. Rees; "The Action of Heat on Kaolinite and other Clays," Part II, by J. W. Mellor and A. Scott; "The Origin of the Austrian Magnesite Deposits," by A. Scott; "X-ray Investigation of Clays and other Ceramic Substances. Researches into the Application and Practical Value of the Method," by A. Hadding; "Note on the Storage of Silica Refractories," by W. J. Rees; "The True Specific Gravity and After Expansion of Lime-bonded Silica Bricks," by W. J. Rees; "A Rapid Method for the Determination of True (or Powder) Specific Gravity," by W. Hugill and W. J. Rees.

SOCIETY OF CHEMICAL INDUSTRY

CHEMICAL INDUSTRY DINNER

The Autumn Dinner, which will be under the auspices of the Society of Chemical Industry and the Chemical Industry Club, will be held in the Edward VII Rooms of the Hotel Victoria, Northumberland Avenue, London, W.C. 2, on Friday, November 14, at 7 for 7.30 p.m., and will be presided over by Mr. W. J. U. Woolcock, C.B.E., President of the Society.

A circular letter with further particulars and a form of application for tickets is being issued to members.

BACK NUMBERS OF JOURNAL

The General Secretary will be glad to hear from Members or Subscribers who have copies of the *Journal* for January 5, 1923, or January 4, 1924, that they are willing to dispose of to the Society.

MANCHESTER SECTION, Session 1924–25

The meetings are held at 7 p.m. on the first Friday of the month, unless otherwise stated, and a programme of the arrangements is being prepared for early issue to the members of the Section.

The Chairman, Dr. H. Levinstein, will preside over the meetings, which commence on October 3, when the President, Mr. W. J. U. Woolcock, C.B.E., will deliver an address entitled "Science and Industry." On November 7 the Joint Meeting with the Local Sections of the Institute of Chemistry, and the Society of Dyers and Colourists, and the Manchester Literary and Philosophical Society will be held. On December 5 Mr. Slater will read an interesting paper on "Peptisation." The valuable series of papers which have appeared on fuel problems will receive an addition on January 9 (second Friday), when Messrs. F. S. Sinnatt and N. Simpkin will contribute a paper entitled "The Melting Point of Coal Ash, Part II." The papers for the February meeting will be detailed later, and Dr. T. Callan and Mr. Naunton have kindly promised communications on the estimation of alpha- and beta-naphthol and rubber accelerators respectively.

The Joint Meeting with the Liverpool Section will take place in Manchester on March 6, when it is hoped to arrange a luncheon and a visit to a works. The evening will be occupied by a paper on "Chemical Constitution and Properties of Azo Dyestuffs" by Dr. A. Schedler.

The Section has received, and has accepted, a cordial invitation from the Institution of the Rubber Industry to participate in a joint meeting to be held in Manchester at a date to be decided later. The suggestion has been made that papers on "Chemists and the Improvement in Pneumatic Tyres" might be read at this meeting.

Dr. Lander, Director of Fuel Research, Department of Scientific and Industrial Research, has accepted an invitation to deliver an address on "Smokeless Fuel and Oil" at the annual meeting of the Section on April 3. The above information is subject to alteration if the necessity arises.

CORRESPONDENCE

A POINT OF ORDER

Sir,—Your issue of August 8 contains some remarks by Professor Lowry (p. 811) on polarity and vinyl ethyl ether. The signs he uses represent the supposed charges on the atoms in his activated form of that compound. The signs used in my letter in your issue of July 25 were intended as generalisations of the final results of chemical changes which take place when the compound reacts with electrolytes, or potential electrolytes. Numerous criticisms nominally directed against the principle of induced alternate polarities and various misapplications of the principle have their origin in a similar confusion of these two aspects of the question.

Professor Lowry now virtually admits that his theory of the activation of the double bond by an oxygen atom is helpless in such a case as that of vinyl ethyl ether, and he evidently suspects that "oxonium chemistry" might supply the key to the mechanism of the activation of the molecule. The correct application of oxonium chemistry to such cases has in my opinion already been given; it was foreshadowed by Claus, Werner and Flürscheim (compare especially Flürscheim, *Ber.*, 1914, **47**, 590), but extended and brought to perfection by Robinson (in particular *J.C.S.*, 1917, **111**, 964). Robinson's expressions representing the theory of the activation of a double bonded system, by a singly bound oxygen atom rising in co-valency, are so complete and so general that any electronic expressions likely to be accepted in the future as capable of covering similar ground will almost certainly prove to be special cases of his generalised forms.

Thus if we adopt the view that a bond corresponds with an electron pair, vinyl ethyl ether (I) can yield the activated oxonium forms which in the limit take the form (Ib), corresponding with Robinson's figure for activated anisole (*loc. cit.*). This also corresponds with Fig. 1 (b) in a much later paper of mine (*J.C.S.*, 1922, **121**, 419) in which an attempt was made to find a general theoretical basis for the facts of which the principle of induced alternate polarities is a summary. Activated forms due to decrease in the covalency of the oxygen atom and corresponding with I (a) (*loc. cit.*), could only arise in opposition to the tendency of even distributions of valency (to which tendency I believe Professor Morgan was the first to direct special attention) and, in the limit, would lead to scission of the molecule as shown below on the left:—

$$\underset{\text{I (a)}}{\overset{\times}{CH_2{=}CH} + {-}O{-}Et} \longleftrightarrow \underset{\text{(I)}}{CH_2{=}CH{-}O{-}Et} \longleftrightarrow \underset{\text{I (b)}}{CH_2{-}CH{=}O{-}Et}$$

(× is here used to denote a defect of two electrons.)

If the electrical states of the atoms in the oxonium form, I (b), are considered, it will be noticed (assuming Prof. Lowry's criteria for such are correct, and I have no desire to join issue with him on this point) that the carbon atom of the CH_2 group must be negatively charged, that of the CH group electrically neutral, and that the oxygen atom must be positively charged as in ordinary oxonium salts. It will be observed that Robinson's formulæ for the activated oxonium forms of *m*-cresol (*loc. cit.*) actually display the oxygen atom as having a positive free affinity.

It is evident that, while the signs in the expression, $\bar{C}H_2{=}\overset{+}{C}H{-}\bar{\overset{+}{O}}{-}Et$, represent satisfactorily such facts as they were originally intended to represent, they are not all identical with the electrical charges in the activated molecules. Identities occur at certain points, however, and by paying attention to these the theoretical significance of the alternate polarity signs may be more readily grasped.

As Prof. Lowry's signs always refer to supposed electrical charges, there is just as wide a distinction in meaning to be drawn between his signs and those which I have since 1920 endeavoured consistently to use (though perhaps not always with complete success), as there is between the expressions "electropositive" and "positively charged."—I am, Sir, etc.,

ARTHUR LAPWORTH

The University of Manchester,
August 29, 1924

METHANOL

Sir,—I have noted with great interest the communication from the Federation of Swedish Chemical Industries under the above heading. In January, 1918, I read a paper before the London Section of the Society of Chemical Industry on the "Toxicity of Methyl Alcohol." Therein I pointed out that the Revenue Authorities are bound under the Spirits Act (which badly needs amending) to classify pure methyl alcohol as "plain" or "potable" spirits with the result that British chemical industry is handicapped by the usual Revenue control and restrictive conditions.

I suggested that methyl alcohol should be known by its scientific name of "Methanol" and that it be labelled "Poison." Let me quote one paragraph from the paper referred to (*J.S.C.I.*, 1918, **36**, 26 T—32 T):—

"We may revert now to my claim earlier in this paper that methyl alcohol is highly toxic and for that reason the Revenue Authorities should have no fear that it can be consumed as 'potable spirit.' Then why tax it as 'plain spirits'? Why penalise British chemical industry by taxation of a 'key' chemical? One may suppose that if methyl alcohol had been called by some other less alcoholic name it would never have been classified as 'spirits' at all."

Other countries do not find it necessary to regard methyl alcohol as "potential whiskey," and the only reason why the British Revenue Authorities do so is because we are labouring under an obsolete Act of Parliament.

There is only one method of dealing with this problem. Let all concerned in the welfare of the British chemical industry unite to promote an *Amending Bill to the Spirits Act.* The time is opportune. The President of the Society knows full well that much time has been devoted to the question of

he restrictions of the use of ethyl and methyl alcohol y committees appointed by the Council of the Association of British Chemical Manufacturers. Furthermore, the conditions regarding the manu-acture of methyl alcohol must be reviewed at an arly date. The successful inauguration of the manufacture of synthetic methyl alcohol in Germany and other countries opens up new possibilities for establishing the manufacture in this country.

Hitherto we have been dependent for our methyl alcohol on those countries with well developed wood-distillation industries. Our own wood distillers have found a ready outlet for their crude methyl alcohol as wood naphtha, and they have not found it necessary o manufacture pure methyl alcohol.

The manufacture of methyl alcohol by synthetic methods in this country is bound to be discouraged, f not actually prohibited, by our obsolete Spirit Laws.

Surely it is not too much to hope that the Society of Chemical Industry will take immediate steps to co-operate with the Association of British Chemical Manufacturers in promoting a Bill to regularise the position of methyl alcohol in respect of the law as to "spirits."

Meanwhile, I may add in conclusion and as some small practical contribution to the subject that my irm is now using the description "Methanol" for methyl alcohol, and all labels and containers for same bear the word "Poison."—I am, Sir, etc.,

THOMAS D. MORSON

Thomas Morson and Son, Ltd.,
Ponders End

PERSONAL AND OTHER ITEMS

The death of Sir William Bayliss deprives science of a great physiologist and an investigator with a wide philosophic outlook. Born in 1866, Bayliss was educated at University College, London, and Wadham College, Oxford. He carried out much important work with Prof. E. H. Starling on subjects such as the regulation of the heart and the action of hormones. In 1914 he published his work on "The Principles of General Physiology," a most remarkable treatise, and in 1919 he received the Copley Medal of the Royal Society. In 1923 he became editor of "Physiological Abstracts," although he was already occupied with much valuable public work.

Low-temperature Carbonisation of Coal in France

At the Fourth Congress of Industrial Chemistry, M. Ste. Claire Deville discussed the work carried out by the coking plant at Heinitz, with the object of improving the coke obtained by carbonising the so-called "fat" coals of the Saar. The work led to the specification of a semi-coke used in the proportion of roughly one-eighth in preparing the mixture for improved coke, and to the construction of a fixed oven with turning paddles by the Société de Fours à Coke. In addition a plant for primary tars under reduced pressure (one-fifth atmospheric) and able to treat five tons at a time was also devised. Numerous coke-ovens were tested, including a small rotary furnace resembling the large ovens of the same type used in the Ruhr. In this model the semi-coke is discharged at each half rotation by a hinged door which opens under its own weight, allowing the coke to fall. Despite the results obtained with this oven, at present trials are being carried out mostly with the Salerni plant, which includes two parts each composed of semi-cylindrical elements with corrugated bottoms placed in parallel and having a common cover. The movement communicated to the mass by turning shafts (one for each element) does not take place along the axis of the cylinder but in a plane parallel to it, the result being to drive the particles of coal from element to element and finally to the discharge. The mixing seems much more complete than in rotary ovens, and the surfaces in contact with the hot walls are continually being renewed. With crushed Velsen coal 100 parts of dry coal yielded 13 parts of anhydrous tar and the semi-coke showed a content of 11 to 12 per cent. of volatile matters. The mixing during carbonisation thus seems to have a favourable effect somewhat similar to that of injected steam, the minimum temperatures at which distillation commences being reduced, so that less heat is required and the plant lasts longer.

The administration of the Saar Mines is now building near Sarrebruck a small works for experiments on low-temperature carbonisation, including plant for treating tar and liquid fuels. The plant includes two batteries of Salerni elements which can deal with 30 to 40 tons of fuel per 24 hours. A precise scientific programme has been mapped out for this new works.

Artificial Silk

In 1913 the production of artificial silk was estimated at 9000 t., and 1922 at 31,000 to 32,000 t. The 1923 figures are uncertain, estimates ranging from 31,200 t. to 42,000 t.

Natural silk production is confined to those countries where the silk worm can thrive, but artificial silk manufacture is almost independent of consideration of raw materials and thus becomes established where the demand exists. The largest market is found in the United States, which besides producing one-third of the world's total output also imports further supplies. The largest exports of artificial silk are made from Belgium, which produces 10 per cent. of the world's total. France, with about the same production, has to import. From Germany, which produces about 16 per cent. of the world's total, a certain amount is exported.

Although the total production of textiles is now less than before the war it is noteworthy that production of both natural and artificial silk has increased, the former by about 25 per cent., the latter by over 200 per cent. The cause of this is to be found in the extension in the use of silk and artificial silk articles in America, where they are no longer regarded as luxuries; also artificial silk, which even in 1913 cost only one-third as much as natural silk, has in comparison with other textiles, become still cheaper.

REVIEWS

THE PLANT ALKALOIDS. By T. A. HENRY. Second Edition. Pp. viii+456. London: J. and A. Churchill, 1924. Price 28s.

The alkaloids interest a wider field than many groups of chemical compounds. Their occurrence in plants challenges the botanist's attention and their physiological action that of the pharmacologist, whilst the chemist is concerned with their isolation, estimation and structure. Moreover, many of them are employed medicinally and reach the patient by way of the medical man, the pharmacist, and the manufacturing chemist. Even the interest of the general public is occasionally directed to these compounds by cases of poisoning, accidental or otherwise. It is possible, therefore, to write of alkaloids from several points of view and for several classes of readers.

Dr. Henry has written for the chemist, assuming that he desires to know something about the physiological action of these compounds. His book is at the same time an admirable catalogue of the chemical and physical properties of the alkaloids and their salts, and a readable account of the methods employed in determining their constitutions and effecting their syntheses. The sources of alkaloids and the methods of isolating and estimating them are also adequately recorded. The alkaloids of known constitution are arranged in nine groups, according to their nuclear structure, as derivatives of pyrrole, pyridine, tropane, quinoline and so on, whilst those of unknown constitution are collected in a tenth group. Dr. Henry is to be congratulated on his excellent treatise, which will prove valuable more especially as a work of reference, the original papers being cited very fully, but also as a text-book for advanced students.

This second edition appears eleven years after the first, and in the meantime considerable additions have been made to our knowledge of this group of compounds. The structures of cryptopine, harmine, and hyoscine have been determined, cocaine has been synthesised, and new syntheses of tropine devised. A new formula for morphine has been put forward, and novel suggestions as to the methods of phytochemical synthesis of alkaloids. Many new alkaloids have been isolated, and progress has been made in the study of many previously known. The new work has been thoroughly digested and incorporated in the second edition. Expansion of the size of the volume has been avoided by various methods, but mainly by two, namely, by decreasing the unnecessarily sumptuous inter-linear spacing of the pre-war edition, so that each page now bears another half-dozen lines, and by cutting out the methods of assay of galenical preparations, which are of interest only to pharmacists, who can obtain them equally well from other sources. The introduction of a few plates, illustrating drugs, into the new volume seems, however, inconsistent with the latter policy. Another wise method of condensation is the omission of alleged manufacturing processes such as the futile method of isolating the solanaceous alkaloids given in the previous edition (pp. 50, 51). On the other hand, the percentage-content of some of the subsidiary alkaloids in opium, such as papaverine, should not have been left out. The reviewer takes this opportunity of disinterring the statement (Jowett, Pyman and Remfry, *Proc. 8th Internat. Cong. App. Chem.*, 1912, p. 165), quite excusably overlooked by the author, that Dale was unable to confirm the atropine-like action attributed to 1-ethyl-2-methylglyoxaline by Schulz.

FRANK LEE PYMAN

MODERN THEORY AND PRACTICE OF PUMPING. By NORMAN SWINDIN. Pp. 364. London: Ernest Benn, Ltd., 1924. Price 42s.

This book can be strongly recommended to all those who have to deal with pumping problems of any magnitude, and to the reviewer it has been a pleasure to study this excellent unification and expansion of the author's two previous books which were published in the "Chemical Engineering Library" of Messrs. Ernest Benn, Ltd. Not only in the various phenomena attendant on the movement of liquids, but in many other branches of engineering, whether distinguished by the prefix of chemical or not, there has been a wide gap between the work of the theoretical experimentalist or mathematician, and that of the purely practical industrialist. In many cases, however, there are happy indications that this gap is becoming less and, in the particular case of pumping, it is highly satisfactory that the scientific and practical aspects can now be almost completely correlated, and that the empirical formulæ, which alone have been available previously, and have in many ways tended to make confusion worse confounded, may be relegated to the rubbish heap.

Stanton's law, which is so clearly expounded in this book, presents a scientific method of calculating the flow of viscous liquids independent of all empirical factors except that of roughness of surface. What must be known when any particular liquid is under consideration is the kinematical viscosity, *i.e.*, the ratio of absolute viscosity to density, but, if that is known, the necessary calculations are simply and easily effected. The effect of roughness of surface and of pipe fittings slightly modifies the results obtained by the use of the law which assumes continuous straight pipes without any joints. Where it is necessary to make allowance for departure from the ideal conditions and until further experimental work has been carried out, sufficient approximations based on experience can be safely utilised without seriously affecting the results. One must not swallow a camel and strain at a gnat, nor accept a scientific solution of an old difficulty and quibble at a few details which are not at the moment accurately determined.

The chapters dealing with the various types of pumps and ram, the centrifugal, the rotary and the displacement are very satisfactory, and the different form which each takes under varying conditions of service are explained with the aid of well-chosen examples made by various firms in this and other countries. The author has devoted special attention to the air lift, which undoubtedly could be of con-

ıerable practical value in many cases, and it is ıimed that if the same attention were given to its sign as has been given to that of other appliances, efficiency of 80 per cent. should be possible.

There are a few printing errors such as "connecon" for "correction" (p. 30), $P = P_1$ instead of $- P_1$ (p. 95) and so on, but on the whole there is ry little fault to find in this respect. The paper ıd printing are all that could be desired, and the blication reflects great credit on both author and ıblishers. It is a valuable contribution and of prac-ıal value to both the makers and users of pumps.

C. Elliott

ATERPROOFING TEXTILE FABRICS. By H. P. PEARSON. Pp. 112. New York: Chemical Catalog Company, Inc., 1924. Price $3.00.

The book is an attempt to supply an authoritative xt-book on the subject, which is described as a tle-understood art having a meagre literature. ne chapters, occupying, however, only sixty-three ges, deal with basic principles; the value of water ısisting processes; the testing of water resistance; ocesses for cotton goods, clothing fabrics and for e former, and new developments; the rest of the lume is given up to a bibliography of the subject. ıe processes described are said to be published for e first time and the information to be derived from ıstworthy sources in the industry; it is said to be fficiently concise to enable anybody with a knowlge of the finishing of textile fabrics to go into e waterproofing industry. Later, however, it is ıd that there is little profit in that industry because keen competition, and the author states that the lustry will never be remunerative as long as no leration of waterproofers exists. In fact, since left this country he seems to have become obsessed th such commercial considerations. A federation waterproofers would compel the education of the y cleaner, who removes by his solvent the material ıich is put into the fabric to make it water resistant. ɔst articles of clothing are not treated to make em water resisting, but the treatment is coming ore into use, and effort is required to educate the ıblic as to its value. Being principally a descripɔn of processes, the book does not admit of much iticism, and being a small one it is worth the rusal of those engaged in the industry which it ıats and on kindred industries.

S. H. Higgins

Good progress is being made in the development of ·dro-electric power in the Lakes St. John and enogami district, Quebec. The principal source of wer, in this district, is the Grand Discharge on the guenay River, at the outlet of Lake St. John. ıe latter has an area of 400 sq. miles, and drains a ıter shed of about 30,000 sq. miles. The drop from ıke level, within a few miles, is 145 feet. This ıole district has available over 1,650,000 h.p., of ıich only 450,000 h.p. is under development and veloped at the present time.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech.	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder	£47 per ton.
Acid Hydrochloric	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw.	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non-arsenical, £6 15s. per ton.
Ammonia Alkali	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder	Spot £11 d/d.: Contract £10 d/d. 4 ton lots.
Bisulphite of Lime	£7 per ton, packages extra.
Borax, Commercial—	
Crystal	£25 per ton.
Powder	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride	£5 17s. 6d. per ton d/d.
Copper Sulphate	£25 per ton.
Methylated Spirit 64 o.p.—	
Industrial	3s. 1d.—3s. 5d. per gallon, according to quantity.
Mineralised	4s. 2d.—4s. 6d.
Nickel Sulphate	£38 per ton d/d. Normal business.
Nickel Ammon. Sulphate	£38 per ton d/d. Normal business.
Potash Caustic	£30—£33 per ton.
Potass. Bichromate	5¾d. per lb.
Potass. Chlorate	3d.—4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake	£3 10s. per ton d/d.
Soda Caustic, solid	Spot lots: delivered. £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98%	£24 per ton.
Sod. Bicarbonate	£10 10s. per ton, carr. paid.
Sod. Bichromate	4½d. per lb.
Sod. Bisulphite Powder 60/62%	£18—£19 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96%	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst.	£9 per ton d/d.
Sod Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1 cwt kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	5¾d.—1s. 4d. per lb., according to quality.

Antimony sulphide—
Crimson .. .. 1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic, Sulphide, Yellow 1s. 11d. per lb.
Barytes .. .. .. £3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide .. 3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide .. £30—£33 per ton, according to quantity. Again dearer.
Carbon Black .. .. 7d.—7½d. per lb. ex wharf. Dearer.
Carbon Tetrachloride .. £60—£65 per ton, according to quantity, drums extra. Again dearer.
Chromium Oxide, green .. 1s. 3d. per lb.
Indiarubber Substitutes White and Dark .. 5d.—9½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black .. .. £48 per ton, barrels free. Advanced.
Lead Hyposulphite .. 7½d. per lb.
Lithopone, 30% .. .. £22 10s. per ton.
Mineral Rubber "Rubpron" .. .. .. £16 5s. per ton f.o.r. London.
Sulphur .. .. .. £10—£12 per ton, according to quality.
Sulphur Precip. B.P. .. £56—£57 per ton, according to quantity.
Sulphur Chloride .. 4d. per lb., carboys extra. Dearer.
Thiocarbanilide .. .. 2s. 6d. per lb.
Vermilion, pale or deep .. 5s. 1d. per lb. dearer.
Zinc Sulphide .. .. 7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

"Summer conditions" prevail in this as in most industries.

Acetate of Lime—
Brown .. .. .. £12—£12 5s. per ton d/d. Market easier.
Grey .. .. .. £17—£18 per ton. Market easier.
Liquor .. .. .. 9d. per gall. 32° Tw.
Charcoal .. .. .. £7 10s.—£9 per ton, according to grade and locality. Demand fairly good.
Iron Liquor .. .. 1s. 7d. per gall. 32° Tw.
1s. 2d. ,, ,, 24° Tw.
Red Liquor .. .. 10d.—1s. per gall. 14/15° Tw.
Wood Creosote .. .. 2s. 7d. per gall. Unrefined.
Wood Naphtha—
Miscible .. .. 4s. 10d.—5s. per gall. 60% O.P. Market dull.
Solvent .. .. .. 5s. 6d. per gall. 40% O.P. Fairly good demand.
Wood Tar .. .. £4 per ton. Cheaper.
Brown Sugar of Lead .. £44 per ton. Cheaper.

TAR PRODUCTS

Acid Carbolic—
Crystals .. .. 6½d. per lb. Quiet.
Crude 60's .. .. 1s. 9d.—1s. 11d. per gall, according to district. Still quiet.
Acid Cresylic, 97/99% .. 2s.—2s. 1d. per gall. Demand fair.
Pale 95% .. .. 1s. 9d.—2s. per gall.
Dark .. .. .. 1s. 9d.—2s. per gall. Quiet.
Anthracene Paste 40% .. 4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—
Strained .. .. 7½d.—9d. per gall. Quiet.
Unstrained .. .. 6½d.—7½d. per gall.
Benzole—
Crude 65's .. .. 10½d.—1s. per gall, ex works in tank wagons.

Benzole—
Standard Motor .. 1s. 4½d.—1s. 6d. per gall. ex works in tank wagons.
Pure .. .. .. 1s. 8½d.—1s. 10d. per gall. ex works in tank wagons.
Toluole—90% .. .. 1s. 5d.—1s. 5½d. per gall. Small demand.
Pure .. .. .. 1s. 8d.—2s. per gall. Small demand.
Xylol coml. .. .. 2s. 3d. per gall.
Pure .. .. 3s. 3d. per gall.
Creosote—
Cresylic 20/24% .. 8½d. per gall. Not much business.
Middle Oil .. .. / Heavy Oil .. .. / Standard Specification — 5d.—6½d. per gall., according to quality and district. Small export inquiry. Market quiet but fairly steady.
Naphtha—
Solvent 90/160 .. 11d.—1s. 5d. per gall., according to district. Fair demand.
Solvent 90/190 .. 11d.—1s. 4d. per gall. Fair demand.
Naphthalene Crude—
Market dull. Not much export inquiry. Cheaper in Yorkshire than Lancashire.
Drained Creosote Salts £4—£6. Quiet.
Whizzed or hot pressed £7—£9 per ton.
Naphthalene—
Crystals and Flaked .. £13—£16 per ton in Yorkshire and London respectively.
Pitch, medium soft .. 55s.—60s. per ton f.a.s. for next season. Frequent inquiries.
Pyridine—90/160 .. 19s. per gall. Again dearer. Market firm.
Heavy .. .. 12s.—12s. 6d. Little business.

INTERMEDIATES AND DYES

Business in dyestuffs has not been good lately, but an improvement is expected after the holidays. Prices remain firm.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% .. 1s. 7d. per lb.
Acid H. .. .. .. 4s. per lb. 100% basis d/d.
Acid Naphthionic .. 2s. 4d. per lb. 100% basis d/d.
Acid Neville and Winther 5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech. .. 1s. 1d. per lb. Improved demand.
Acid Sulphanilic .. 9½d. per lb. 100% basis d/d.
Aluminium Chloride, anhyd. 1s. per lb. d/d.
Aniline Oil .. .. 7½d.—8½d. per lb. naked at works.
Aniline Salts .. .. 7¾d.—9d. per lb. naked at works.
Antimony Pentachloride 1s. per lb. d/d.
Benzidine Base .. .. 4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95% .. 1s. 1d. per lb.
p-Chlorphenol .. .. 4s. 3d. per lb. d/d.
p-Chloraniline .. .. 3s. per lb. 100% basis.
o-Cresol 19/31° C. .. 4½d. per lb. Demand steady.
m-Cresol 98/100% .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C. .. 2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline .. .. 3s. per lb.
Dichloraniline S. Acid .. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol .. .. £85 per ton.
Diethylaniline .. .. 4s. 6d. per lb. d/d., packages extra, returnable.
Dimethylaniline .. .. 2s. 3d. per lb. d/d. Drums extra.
Dinitrobenzene .. .. 9d. per lb. naked at works.
Dinitrochlorbenzol .. £84 10s. per ton d/d.
Dinitrotoluene—48/50° C. 8d.—9d. per lb. naked at works.
66/68° C. 1s. 2d. per lb. naked at works.
Diphenylamine .. .. 2s. 10d. per lb. d/d.
Monochlorbenzol .. .. £63 per ton.
βNaphthol .. .. 1s. 1d. per lb. d/d.
αNaphthylamine .. .. 1s. 4d. per lb. d/d.

aphthylamine	.. 4s. per lb. d/d.
Nitraniline	.. 4s. 9d. per lb. d/d.
Nitraniline ..	.. 2s. 3½d. per lb. d/d.
trobenzene ..	.. 5½d.—5¾d. per lb. naked at works.
Nitrochlorbenzol	.. 2s. per lb. 100% basis d/d.
tronaphthalene	.. 10½d. per lb. d/d.
Nitrophenol ..	.. 1s. 9d. per lb. 100% basis d/d.
Nitro-o-amido-phenol	4s. 6d. per lb. 100% basis.
Phenylene Diamine	.. 4s. per lb. d/d.
Phenylene Diamine	.. 10s. 3d. per lb. 100% basis d/d.
Salt	.. 2s. 6d. per lb. 100% basis d/d.
dium Naphthionate	.. 2s. 3d. per lb. 100% basis d/d.
Toluidine ..	.. 8½d. per lb.
Toluidine ..	.. 3s. 6d. per lb. naked at works.
Toluylene Diamine	.. 4s. 3d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

id, Acetic 80% B.P.	.. £45 per ton.
id, Acetyl Salicylic	.. 3s. 2d.—3s. 4d. per lb., according to quantity. Good demand. Price firm.
id, Benzoic B.P.	.. 3s. per lb.
id Boric B.P. ..	.. Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
id, Camphoric ..	.. 19s.—21s. per lb.
id, Citric ..	.. 1s. 4½d.—1s. 5d. per lb., less 5% for ton lots. Market very weak.
id, Gallic ..	.. 3s. per lb. for pure crystal.
id, Pyrogallic, Cryst.	.. 6s. 9d. per lb. Resublimed quality 8s. per lb. Market firm; increasing demand.
id, Salicylic ..	.. 1s. 6d.—1s. 9d. per lb. Market little better, but demand fluctuating.
id, Tannic B.P.	.. 3s. per lb. Market quiet.
id, Tartaric ..	.. 1s. 1¼d. per lb. less 5%.
nidol	.. 9s. per lb. d/d.
etanilide ..	.. 2s. 1d.—2s. 3d. per lb. for quantity. Demand slow.
nidopyrin ..	.. 13s. 3d. per lb. Neglected. Stocks low.
nmon. Benzoate	.. 3s. 3d.—3s. 6d. per lb. according to quantity.
nmon. Carbonate B.P.	£37 per ton.
ropine Sulphate	.. 12s. 6d. per oz. for English make.
rbitone	.. 15s.—15s. 6d. per lb. Quiet market.
nzonaphthol ..	.. 5s. 3d. per lb. Small inquiry.
smuth Salts ..	.. Prices reduced by about 1s. 3d.—2s. 3d. per lb. on account of the fall in the price of the metal.
smuth Carbonate	.. 10s. 6d.—12s. 6d. per lb.
,, Citrate ..	.. 10s. 3d.—12s. 3d. ,,
,, Salicylate	.. 9s.—11s. ,,
,, Subnitrate	.. 8s. 8d.—10s. 8d. ,,
orax B.P. ..	.. Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
omides	.. Market exceedingly firm, and material rapidly advancing. Spot supplies very limited.
Ammonium ..	.. 1s. 4d.—1s. 7d. per lb.
Potassium ..	.. 1s. 2d.—1s. 5d. per lb.
Sodium	.. 1s. 3d.—1s. 6d. per lb.
lcium Lactate ..	.. Market fairly firm and higher prices talked of. Good English make can be had from 1s. 6d. upwards.
loral Hydrate ..	.. 4s.—4s. 3d. per lb. Very firm and scarce.
loroform ..	.. 2s. per lb. for cwt. lots. Very steady.
eosote Carbonate	.. 6s. 6d. per lb. Little demand.
rmaldehyde ..	.. £52 per ton, *ex* works. English make in casks.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free ..	.. 7s. per lb.
Iron	.. 8s. 9d. per lb.
Magnesium ..	.. 9s. per lb.
Potassium, 50%	.. 3s. 6d. per lb.
Sodium, 50% ..	.. 2s. 6d. ,,
Guaiacol Carbonate	.. 10s. 6d.—11s. 3d. per lb.
Hexamine ..	.. 3s. 6d. per lb. for English make—market steady.
Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor	.. English make offered, 120s. per oz.
Hypophosphites—	
Calcium ..	.. 3s. 6d. per lb., for 28-lb. lots.
Potassium ..	.. 4s. 1d. per lb.
Sodium ..	.. 4s. ,,
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb., according to quantity.
Magnesium Carbonate—	
Light Commercial	.. £36 per ton net.
Magnesium Oxide—	
Light Commercial	.. £75 per ton, less 2½%.
Heavy Commercial	.. £25 per ton, less 2½%. Price reduced.
Heavy Pure ..	.. 2s. 2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	.. 57s. 6d. per lb.
Synthetic ..	.. 26s.—35s. per lb., according to quantity. English make. Strong demand.
Mercurials ..	.. Market very quiet.
Red oxide ..	.. 5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	.. 3s. 6d.—3s. 7d. ,,
White precip. ..	.. 4s. 7d.—4s. 8d. ,,
Calomel ..	.. 3s. 11d.—4s. ,,
Methyl Salicylate	.. 1s. 10d.—2s. 1d. per lb. Keen competition.
Methyl Sulphonal	.. 26s. per lb.
Metol	.. 11s. per lb. British make.
Paraformaldehyde	.. 2s. 10½d.—3s. per lb. Not very active.
Paraldehyde ..	.. 1s. 5d.—1s. 6d. per lb. in free bottles and cases.
Phenacetin ..	.. 6s. per lb. Price and demand steady.
Phenazone ..	.. 7s. 6d. per lb. A shade firmer. Forward prices higher.
Phenolphthalein ..	.. 6s. 6d. per lb. Ample supplies.
Potass. Bitartrate—99/100% (Cream of Tartar) ..	.. 88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate ..	.. 1s. 10d.—2s. 2d. per lb.
Potass. Iodide ..	.. 16s. 8d.—17s. 5d. per lb., according to quantity. Good steady demand.
Potass. Metabisulphite	.. 7½d. per lb., 1-cwt. kegs included.
Potass. Permanganate	.. 7¼d. per lb.
Quinine Sulphate	.. 2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	.. 5s. 2d. per lb.
Saccharin ..	.. 63s. per lb., in 50-lb. lots.
Salol	.. 3s. 6d. per lb.
Silver Proteinate ..	.. 9s. 6d. per lb.
Sod. Benzoate, B.P.	.. 2s. 6d. per lb. Ample supplies. B.P. quality available.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite—Photographic ..	.. £13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.

Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside ..	16s. per lb. Less for quantity.
Sod. Potass. Tartrate (Rochelle Salt) ..	75s.—82s. 6d. per cwt., according to quantity. Steady market, good demand.
Sod. Salicylate	Market rather firmer and more enquiry. Powder 2s. 3d.—2s. 5d. per lb. Crystal at 2s. 5d.—2s. 7d. per lb. Flake 2s. 9d. per lb.
Sod. Sulphide—Pure recryst.	10d.—1s. 2d. per lb., according to quantity.
Sod. Sulphite, anhydrous	£27 10s.—£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal	15s. 6d. per lb. Easier.
Thymol	20s. per lb. nominal. Very scarce indeed nominally.

PERFUMERY CHEMICALS

Acetophenone	12s. 6d.	per lb.	
Aubepine	15s. 3d.	,,	
Amyl Acetate	2s. 6d.	,,	Cheaper.
Amyl Butyrate	6s. 9d.	,,	
Amyl Salicylate	3s.	,,	
Anethol (M.P. 21/22° C.)	4s. 6d.	,,	
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 9d.	,,	
Benzyl Alcohol free from Chlorine	2s. 9d.	,,	
Benzaldehyde free from Chlorine ..	3s. 6d.	,,	
Benzyl Benzoate	3s. 6d.	,,	
Cinnamic Aldehyde—Natural	16s.	,,	
Coumarin	19s. 6d.	,,	
Citronellol	17s.	,,	
Citral	8s. 6d.	,,	Cheaper.
Ethyl Cinnamate ..	12s. 6d.	,,	,,
Ethyl Phthalate	3s. 3d.	,,	
Eugenol	10s. 6d.	,,	
Geraniol (Palmarosa)	[illegible]5s.	,,	
Geraniol	11s.—18s. 6d.	per lb.	
Heliotropine	7s. 3d.	,,	
Iso Eugenol	15s. 9d.	,,	
Linalol ex Bois de Rose ..	26s.	,,	
Linalyl Acetate	26s.	,,	
Methyl Anthranilate ..	9s. 6d.	,,	
Methyl Benzoate	5s.	,,	
Musk Ambrette	45s.	,,	
Musk Xylol	14s.	,,	
Nerolin	4s. 9d.	,,	
Phenyl Ethyl Acetate ..	15s.	,,	
Phenyl Ethyl Alcohol ..	16s.	,,	
Rhodinol	60s.	,,	Advanced.
Safrol	1s. 10d.	,,	
Terpineol	2s. 4d.	,,	
Vanillin	26s. per lb.		

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	1[illegible]s. 6d. per lb.
Aniso Oil	[illegible]s, 6d. per lb.
Bergamot Oil	17s. 6d. per lb.
Bourbon Geranium Oil ..	36s. 6d. per lb.
Camphor Oil	65s. per cwt.
Cananga Oil Java	10s. 6d. per lb.
Cinnamon Oil, Leaf ..	6½d. per oz.
Cassia Oil 80/85% ..	10s. per lb. Advanced.
Citronella Oil—Java 85/90%	5s. 8d. per lb.
Ceylon	3s. 7d. per lb.
Clove Oil	7s. 6d. per lb. Cheaper.
Eucalyptus Oil 70/75% ..	2s. 3d. per lb.
Lavender Oil—French 38/40% Esters	27s. 6d. per lb. Cheaper.
Lemon Oil	3s. per lb.
Lemongrass Oil	3d. per oz.
Orange Oil, Sweet ..	12s. per lb.
Otto of Rose Oil—Bulgarian	37s. 6d. per oz. Production below average.
Anatolian	18s. per oz.
Palma Rosa Oil	18s. per lb.
Peppermint Oil—Wayne County ..	22s. 9d. per lb. Firm spot and forward.
Japanese	17s. per lb. Market firm.
Petitgrain Oil	9s. 3d. per lb.
Sandal Wood Oil—Mysore	26s. 7d. per lb.
Australian	21s. per lb.

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, 15 days after the date given.

I.—Applications

Brégeat. Recovery of volatile sovents. 19,829. Aug. 21.

Cook and Gallimore. Ovens and furnaces. 19,669. Aug. 20.

Davies and Johnston. Apparatus for heating granular material. 19,624. Aug. 19.

Gibbons Bros., Ltd., and Van Marle. Muffle furnaces. 19,863. Aug. 22.

Kerr and Lambert. Apparatus for heating liquids. 19,838. Aug. 21.

Lenart. Centrifugal mills for grinding colours etc. 19,735. Aug. 20.

Sauer. Manufacture of adsorbent materials. 19,596. Aug. 19. (March 26, 1923.)

I.—Complete Specifications Accepted

10,139 (1923.) McClelland. Apparatus for removing solid impurities and scum from steam and other boilers, evaporators, clarifiers, and similar apparatus. (220,348.)

24,036 (1923). Fasting. Rotary kilns. (205,069.)

32,617 (1923). Karpinsky and Anderson. Centrifugal separators. (214,577.)

2391 (1924). Akt.-Ges. Kummler and Matter. Liquid evaporators. (210,464.)

II.—Applications

Butterworth and Mumford. 19,791. *See* III.

Dorgelo. 19,896. *See* XXIII.

Dvorkovitz. Means for treatment of coal etc. 19,580. Aug. 18.

Evans. Production of coke. 19,653. Aug. 19.

Geipert. Apparatus for manufacture of generator or producer gas. 19,814. Aug. 21.

Klusmeyer. Carburetting raw and heavy oils. 19,929. Aug. 22.

Laing and Nielsch. Distillation etc. of carbonaceous etc. materials. 19,769. Aug. 20.

Sauer. 19,596. *See* I.

II.—Complete Specifications Accepted

10,251 (1923). Lane. Composition for use as a substitute for bitumen. (220,349.)

13,448 (1923). Atherton. Bituminous compositions. (220,393.)

23,084 (1923). Soc. Ricard, Allenet, et Cie. Apparatus r dehydrating mixtures of alcohol and liquid hydrocarbons. 04,697.)

31,508 (1923). Fülscher. Apparatus for cooling incan-escent coke. (208,557.)

2805 (1924). Fabry. Construction of coke oven heating-tes. (220,556.)

I.—Applications

Butterworth and Munford. Preparation of tar, bitumen, .c. for roads etc. 19,791. Aug. 21.

Sulzer Frères Soc. Anon. Tar distillation apparatus.),703. Aug. 20. (Switz., 15.12.23.)

/.—Applications

Farbwerke vorm. Meister, Lucius, and Brüning. Manu-cture of vat dyestuffs containing sulphur. 19,818. Aug. 21. Ger., 17.9.23.)

Lenart. Manufacture of thick oil from linseed etc. oils.),815. Aug. 21.

—Applications

Bate, British Dyestuffs Corporation, and Perkin. 19,889. ee VI.

Bemberg Akt.-Ges. Spinning artificial silk. 19,759. ug. 20. (Ger., 5.11.23.)

Bemberg Akt.-Ges. Apparatus for spinning artificial silk.),760. Aug. 20. (Ger., 17.11.23.)

Craig and Spence and Sons. Fire-proofing textile fibres etc.),515. Aug. 18.

—Complete Specifications Accepted

26,572 (1923). British Celanese, Ltd. (formerly British ellulose and Chemical Manufacturing Co., Ltd.), and Ellis. ee VI.

27,174 (1923). Hopkinson, Morgan and Wright. See XIV.

I. Applications

Bate, British Dyestuffs Corporation, and Perkin. Dyeing etyl silk. 19,889. Aug. 22.

Johnson (Smith, Drum, and Co.). Agitating-devices for ye-vats etc. 19,659. Aug. 19.

Ransford (Cassella und Co. Ges.). Dyeing. 19,733. ug. 20.

'I.—Complete Specification Accepted

26,572 (1923). British Celanese, Ltd. (formerly British ellulose and Chemical Manufacturing Co., Ltd.), and Ellis. yeing or colouring of products made with cellulose acetate. 20,505.)

II.—Applications

Blackburn. Manufacture of ammonia. 19,655. Aug. 19.

Franco. Manufacture of salt etc. 19,960. Aug. 23.

Sakurai and Suzuki. Process of producing an acid and s salts strongly absorbing ultra-violet rays. 19,568. Aug. 18.

Synthetic Ammonia and Nitrates, Ltd. Treating gases earing gaseous synthetic ammonia. 19,511. Aug. 18. (U.S., 5.8.23.)

Thomas. Manufacture of ammonia. 19,655. Aug. 19.

II.—Complete Specifications Accepted

15,401 (1923). Krafft. Processes for the purification of urner gases and for obtaining chemically-pure sulphuric cid. (220,413.)

22,616 (1923). Mond (Chemische Fabrik Griesheim Elek-ron). Process for the production of aluminium-fluoride-lkali-fluoride double compounds technically free from iron. 03,708.)

1276 (1924). Wefelscheid. Process of and apparatus for e production of lead oxide. (220,548.)

III.—Application

Skold. Manufacture of magnesium boro-silicate glass.),768. Aug. 20.

X.—Application

Butterworth and Munford. 19,791. See III.

IX.—Complete Specification Accepted

24,036 (1923). Fasting. See I.

X.—Applications

Booth, British Vacuum Cleaner and Engineering Co., and Came. Recovery of gold. 19,642. Aug. 19.

Haagn and Heraeus. Alloys for tipping metallic surfaces. 19,839. Aug. 21.

Heraeus. Alloys for tipping metallic surfaces. 19,832. Aug. 21. (Ger., 10.9.23.)

Metals Production, Ltd., and Perkins. Leaching ores etc. 19,910. Aug. 22.

Wellesley. Alloys. 19,666. Aug. 19.

X.—Complete Specifications Accepted

12,499 (1923). Wade (Naamlooze Vennootschap Philips' Gloeilampenfabrieken). Process of separating zirconium and hafnium. (220,358.)

12,500 (1923). Wade (Naamlooze Vennootschap Philips' Gloeilampenfabrieken). Process of separating hafnium and zirconium. (220,359.)

13,727 (1923). Turnbull. Baths for galvanising. (220,398.)

XI.—Application

Baily. Electric furnaces. 19,875. Aug. 22. (U.S., 28.8.23.)

XI.—Complete Specification Accepted

296 (1924). Electro-Osmose Akt.-Ges. (Graf. Schwerin Ges.). See XVII.

XII.—Applications

Genoocke and Metallbank und Metallurgische Ges. Process of purifying oils and fats. 19,727. Aug. 20. (Ger., 18.9.23.)

Haas. Soaps and washing colloids. 19,884. Aug. 22.

Haddan (Lenart). 19,815. See XIII.

Kiegel. 19,552. See XIXa.

Morgan and Patent Borax Co. Soaps, detergents, etc. 19,667. Aug. 20.

XII.—Complete Specification Accepted

13,307 (1923). Andrews and Rose, Downs and Thompson, Ltd. Thickening and bleaching, or thickening or bleaching of oils. (220,390.)

XIII.—Applications

Brown and Klein. Pigments. 19,907. Aug. 22.

Haddan (Lenart). Manufacture of thick oil from linseed etc. oils. 19,815. Aug. 21.

Lenart. 19,815. See IV.

Soc. of Chemical Industry in Basle. Manufacture of artificial shellac. 19,817. Aug. 21. (Switz., 30.8.23.)

Western Electric Co., Ltd. (Western Electric Co., Inc.). Coating-composition, and process of producing same. 19,618. Aug. 19.

XIII.—Complete Specifications Accepted

13,307 (1923). Andrews and Rose, Downs and Thompson, Ltd. See XII.

1276 (1924). Wefelscheid. See VII.

XIV.—Complete Specification Accepted

27,174 (1923). Hopkinson, Morgan and Wright. Method and apparatus for rubberising filamentary material. (210,397.)

XV.—Applications

Consortium fur Elektrochemische Industrie Ges. Agglutinant or cement. 19,746. Aug. 20. (Ger., 20.8.23.)

Ehrenreich. Process of treating skins of plagiostome fishes. 19,555. Aug. 18. (Fr., 7.12.23.)

Haller and Rosenzweig. Manufacture of artificial horn. 19,924. Aug. 22. (Austria, 23.8.23.)

XVI.—Complete Specification Accepted

13,540 (1923). Carpzow, Mann and Heppes. Production of manures. (220,395.)

XVII.—Application

Chemische Fabrik Pyrgos Ges. and Haller. Manufacture of soluble starch products. 19,660. Aug. 19. (Ger., 21.2.24.)

XVII.—Complete Specification Accepted

296 (1924). Electro-Osmose Akt.-Ges. (Graf Schwerin Ges.). Process for the electro-osmotic purification of saccharine juices. (214,578.)

XVIII.—Complete Specification Accepted

23,084 (1923). Soc. Ricard, Allenet, et Cie. *See* II.

XIXa.—Application

Kiegel. Manufacture of margarine. 19,552. Aug. 18.

XIXb.—Application

Jackson (California Spray-Chemical Co.). Insecticides 19,574. Aug. 18.

XX.—Applications

Austerweil. Preparation of thymol and menthol. 19,797. Aug. 21. (Ger., 21.8.23.)

Fryer and McDougall. Production of heterocyclic compounds containing nitrogen in the ring. 19,562. Aug. 18.

XX.—Complete Specification Accepted

3663 (1924). Wacker Ges. fur Elektrochemische Industrie Ges. Manufacture of acetic anhydride. (211,167.)

XXI.—Application

Campbell. Natural-colour kinematography. 19,706. Aug. 20.

XXII.—Complete Specification Accepted

11,304 (1924). Gerlach. Match-striking composition. (219,646.)

XXIII.—Application

Dorgelo. Determining calorific value gases. 19,896. Aug. 22. (Holl., 1.10.23.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London, S.W. 1) has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number :—*Brazil :* Leather (B.X./1135). *British India :* Metals, hardware (239) ; Leather (B.X./1169) ; Wire, bronze, iron (The Director-General, India Store Department, Branch No. 10, Belvedere Road, Lambeth, S.E. 1). *Canada :* Leather (B.X./1157). *Chile :* Electro-plate, cutlery (B.X./1150). *Cuba :* Silk (257) ; Hardware, paint, varnish (258). *Egypt :* Paper (13781/F.E.). *France :* Leather (B.X./1151). *Greece :* Oils, tin, tinplate, copper, copper sulphate (246). *Norway :* Chemicals, oils (247). *Rumania :* Glasses, rubber hose (251). *South Africa :* Paint, oils (243) ; (572). *Turkey :* Bronze wire (A.X./1270). *Uruguay :* Paint (B.X./1186).

Trade Information

Through the Furnace Door is the title of a pamphlet published by Meldrums, Ltd., of Timperley, Manchester, with the object of showing how economies can be effected in the fuel and labour required for raising steam by installing the Meldrum furnace. The advantages claimed for this furnace are that it enables the steam to be kept continuously at the correct working pressure, whilst being sufficiently elastic to meet any sudden demand, and that it makes use of all kinds of low-grade fuels. Messrs. Meldrums, Ltd., also make special fire bars, stokers suitable for any type of fuel, as well as destructor furnaces that are much in use in municipalities, tanneries and other places where combustible refuse is available. Messrs. Meldrums are so convinced of the merits of their furnaces that they offer to fit them on trial after ascertaining the conditions they have to meet.

Canadian Metallurgy and Mining Notes

The report of the International Nickel Co. for year ended March 31, 1924, shows a net profit of $1,206,786 after deduction of taxes, depreciation, depletion, etc., equivalent, after preferred dividends, to 40 cents a share (par $25) earned on $41,834,600 of outstanding common stock. This compares with $48,170, or 54 cents a share on $8,912,600 preferred stock, in the previous year. After preferred dividends the surplus was $672,030 comparing with a deficit of $486,586 in preceding year.

The Treadwell-Yukon Co., at Keno Hill, Yukon, has struck a big vein of ore at a depth of 600 feet. This settles the question of the Mayo district being a deep mining camp, and assures permanence of these rich silver-lead mines. The higher grade ore is shipped to the smelter, and a mill will be erected by the company to handle the lower grade.

A Glasgow syndicate has purchased 55 iron-ore claims at Goudreau, Ont., the amount involved being approximately $1,500,000. The purchasers propose to develop and use 180,000 h.p. on the Missinaibi River. The new bounty, promised by the Ontario Government, is reported to be the incentive to the mining and concentrating of these low-grade ores.

German iron masters, in the Ruhr district, are endeavouring to close a contract for five years' delivery of iron ore from the Wabana mine of the British Empire Steel Corporation, of Montreal.

The Alberta Salt Co. Ltd., has operations under way for the establishment of a salt plant capable of producing 15,000 to 20,000 tons a year, at Fort McMurray Alta. The latter place is 300 miles north of Edmonton, Alta.

VOL. 43 NEW SERIES | LONDON, SEPTEMBER 12, 1924 | No. 37

EDITORIAL

ONE of the most valuable features of the meetings of the British Association is, perhaps, the arrangement of discussions in which two different sections meet to consider a problem common to both. Discussion of a problem from different standpoints cannot but lead to a clearer understanding of the points involved, so that unprofitable issues can be abandoned and promising lines of work decided upon. It is a very appropriate moment, as Prof. Drummond remarked in opening the discussion on "Vitamins," for chemists and physiologists to meet together to discuss this difficult subject. Already the literature devoted to vitamins is very large, and it is regrettable that so much of the work is nullified by imperfect appreciation of the real nature of the problem. As Prof Drummond says, some workers have failed to differentiate between substances essential for life and growth and those which apparently act rather as stimulants of growth. Caution in interpreting the results of experiments is particularly necessary when the reactions of living organisms are being studied, and the vitamins themselves, despite the skilful wording of Prof. Drummond's definition, are rather vague substances. Real progress cannot be made until we know what a vitamin is as well as what it does, and we await another Annual Meeting when, at least, the synthesis of insulin and the manufacture of a vitamin will be described

We have read somewhere of a Utopian country in which there was no legal system and no lawyers, where the citizens lived solely by the light of reason and for the common weal. There is ground for the belief that such a country would be very dull, however much we should like to find Utopian beginnings in our own times. We are now confronted with an excellent suggestion by the Joint Committee for the Standardisation of Scientific Glassware. The recommendation is unanimous and the membership of the Committee is more than ample warrant of its desirability. If we lived in Utopia we should all, at a given date, abandon the deceitful "c.c." and replace it by the trusty "*ml.*" We do not live in Utopia, and so we read, in the report, that some chemists still prefer to use Mohr's system of units and would be unwilling at present to change their existing practice. But, it is suggested that they shall brand their units with "G.W.A." Did not Shakespeare write "Great G.W.A. doth sway my life," and though there is no hint that the problem is as old as that, there is Florentine guile in the suggestion that the "ml." and "G.W.A." units can be used side by side during the transitional period that must precede the general adoption of the litre and millilitre for general chemical work. The report, which will be found on another page, deserves close attention and should convince all chemists that the time has come when the sibilant "c.c." should no longer be heard in the land. But if conviction is still to seek, why, there is still the transitional period.

Despite the recent and extensive demonstration of our capabilities for which we are still paying, we still seem, as a nation, doubtful of our own powers. "They do things better over there," is still our cry. Our dyestuffs industry has received much blame and but little praise, yet it has gone on, training chemists, making dyes better and better, and steadily improving. In the glass industry, the same process has gone on and laboratory glassware that meets all requirements is produced, but its wartime difficulties are remembered, not its post-war successes. It is sometimes valuable to see how things are really done outside this country. The Berlin correspondent of the *Financial Times* reports that the firms—Bayer, Agfa, Badische, Meister, Lucius, and Bruning, Weiler Ter-Meer, and the Griesheim-Elektron composing the German dyestuff trust, "announce that they can pay no dividend for the past year, as in no instance was their earning sufficient and in some cases work was carried on at a small loss. Results for the current year are not satisfactory."

SOME MODERN TENDENCIES OF VITAMIN RESEARCH *

BY PROF. J. C. DRUMMOND

Probably at no previous stage in vitamin research has it been more appropriate that a joint discussion on this subject between chemists and physiologists should be held than at the present time, for, after much laborious research has been carried out on the distribution of these substances in foodstuffs, and on the significance of vitamins in relation to human dietaries and rations for animals, practical applications which became of urgent importance during and immediately after the years of the war, investigations are now being directed more definitely towards ascertaining the chemical nature of these curious substances, and their mode of action in the animal body.

I would first direct your attention to considering what vitamins are. The classic researches of Hopkins demonstrated that for normal growth and health the higher animals require certain components of natural foods other than proteins, fats, carbohydrates and salts, and to these substances the name vitamins was given by Funk; a name, which, in spite of many objections, has become well established. What, then, are we to regard as a vitamin?

In the present state of our knowledge we may reasonably regard a substance as a vitamin if it is essential to the life and wellbeing of an organism which does not possess the power to synthesise that substance, and also if it is organic in nature, and does not belong to any one of the three great classes of foodstuffs, proteins, fats and carbohydrates. Furthermore, compared with these foodstuffs the vitamins appear to be required by the organism in relatively minute amounts. One of the modern problems of vitamin research is to ascertain to what extent these substances are essential for all living organisms, rather than for the higher animals in particular.

In preparing this paper I have made a careful survey of the available work on this subject, only to find that the literature is in a most confused and unsatisfactory state. If we review very rapidly the more outstanding of these papers, and deal with the organisms more or less according to the evolutionary scale, we are first attracted by the work of Allen and Nelson on the growth of marine diatoms (*J. Marine Biol. Assn.*, 1910, **8**, 361; Allen, *ibid.* 1914, **10**, 417). These observers believed they had obtained evidence of the existence in natural sea-water of a substance, apparently organic, of which minute amounts are necessary for the satisfactory growth of certain marine diatoms. This work has been carefully examined in my laboratory recently by Miss Peach (*Biochemical J.*, 1924, **18**, 364), who finds that the diatom *Nitzschia closterium* can grow satisfactorily in artificial culture media prepared from pure inorganic salts and as free from organic matter as possible. Similar experiments with the organism used by Allen, *Thallassiosira gravida*, are in progress, but are as yet incomplete.

After all, it would in my mind be an extraordinary fact if in the progress of evolution, even simple green plants had lost their autotrophic nature and become to a certain extent dependent on preformed organic matter. The next work which calls for our attention are the researches of Bottomley on the substances which he termed "auximones," present in peat allowed to undergo changes induced by inoculating with cultures of certain soil bacteria. He and his co-workers claimed to have shown that these substances are essential for the growth and development of a number of green plants (*Proc. Roy. Soc. Lond., B.*, 1914, **88**, 237; **89**, 102, 481). Careful re-examination of his work has, as far as I am aware, not yet been undertaken, but his claims are somewhat generally discredited, and are certainly not supported by studies on the growth of plants such as wheat in water cultures. What stands out most clearly from a careful survey of much of this work is the failure to differentiate between substances essential for life and growth and those which appear to act more as stimulants of growth. This will be appreciated even more when the experiments on the lower plants devoid of chlorophyll have been studied. As far back as 1901, Wildiers (*La Cellule*, 1901, **38**, 465) showed that growing cultures of yeast contain a substance to which he gave the name "bios," which he found to be a necessary addition to an artificial medium if a small inoculation of yeast is to grow. Large inoculations would, however, carry their own supply of "bios." This work, which virtually reopened the famous controversy begun between Pasteur and Liebig, and carried on between Mayer and v. Nägeli, has stimulated a large amount of research, particularly since Williams suggested that "bios" is identical with the substance now usually referred to as vitamin B (*J. Biol. Chem.*, 1919, **38**, 465; 1920, **42**, 259), but here again, much confusion has apparently been caused by insufficient distinction being made between substances which merely stimulate growth and others in the absence of which no growth will occur. Undoubtedly, substances are produced during the growth of yeast which, when added to new cultures, tend to stimulate cell multiplication, but the careful experiments of Fulmer Nelson and White (*J. Biol. Chem.*, 1923, **57**, 397) seem to make it clear that *Saccharomyces cerevisiae* can grow in a synthetic artificial medium prepared from inorganic salts and pure sugars, even when for the latter one uses the synthetic sugar, methose. This result may indicate either that yeast growing in such a medium can itself produce the substance which stimulates its own growth, or that the growth of the organism does not require such a substance. The fact that yeasts growing under these conditions synthesise the factor known as vitamin B which has so great an influence on the growth of many species of animals may, perhaps, be taken as evidence in support of the former alternative (*J. Biol. Chem.*, 1923, **56**, 489). If such be the case it is incorrect, as Fulmer, and Nelson (*J. Biol. Chem.*, 1922, **51**, 77),

* Paper read to open the Discussion on "Vitamins" organised by Sections B (Chemistry) and I (Physiology) at the Toronto meeting of the British Association, 1924.

Macdonald (*J. Biol. Chem.*, 1923, **56**, 489) and others have pointed out, to apply the term vitamin to stimulating substances such as "bios," as Funk and Dubin have done (*J. Biol. Chem.*, 1920, **44**, 487).

Regarding the bacteria the facts are less clearly defined than in the case of the yeasts. Certain species such as the sulphur bacteria, studied with such care by Waksman and his colleagues, and the nitrite bacteria, appear able to flourish in a wholly inorganic medium, and to be quite independent of pre-formed organic matter. This is in agreement with what is known concerning their strictly autotrophic character. The vast majority of bacteria, lacking this power to synthesise organic materials from carbon dioxide by utilising the energy made available by simple exothermic reactions, are dependent to a greater or a lesser extent on organic foodstuffs. For many species it has been claimed that in addition they require minute amounts of certain growth stimulants akin to the vitamins (Lloyd, *J. Path. and Bact.*, 1916, **21**, 113; Shearer, *Lancet*, 1917, **1**, 59), particularly in the case of the so-called hæmophilic bacteria (Legroux and Mesnard, *Comptes rend.*, 1920, **170**, 901). A close examination of this work, however, immediately impresses one with the unsatisfactory nature of much of the experimental evidence presented.

Probably the substances in these cases are more of the nature of the yeast "bios," and stimulants of growth rather than essentials.

When we turn to the animal kingdom, having passed by cases of symbiosis between plant and plant and between plant and animal, where the conditions are obviously too complex to investigate in the present state of our knowledge, we find the information available rather less confusing and more reliable. Investigations of the nutritive requirements of the simplest animals seem to show that certain protozoa, at any rate, can be grown for many generations in artificial culture media free from any substances resembling the vitamins. Peters (*J. Physiol.*, 1921, **55**, 1) has maintained the ciliate organism *Colpidium colpoda* for over a year in pure culture in a medium in which the only organic material was ammonium glycerophosphate.

T. B. Robertson insists, however, that during the growth of the protozoon *Enchelys* a substance is found which stimulates cell-division of this organism. Indeed, on the basis of this work he has built up a most elaborate theory of the autocatalytic nature of cell growth. ("The Chemical Basis of Growth and Senescence." London. 1923.)

Attractive as much of his theorising appears at first sight, it must be remembered that, as yet, the experimental foundation is insecure. Cutler and Crump (*Biochem. J.*, 1923, **7**, 174) could obtain no indication of his autocatalytic—or as he prefers to call it, allelocatalytic—effect when studying the growth of *Colpidium*, but, on the other hand, they appear to find that the addition of small quantities of substances similar in nature to "bios" have a marked effect on the growth of this organism.

Once again we must attempt to distinguish between the essential and the non-essential factors, although when one essays to do this the difficulties are at once apparent. If we exclude substances such as "bios," which are believed to be produced by the cell itself, and consider only those elaborated by other cell units, we not only have the essential vitamins, but a host of other factors which in one sense or another are equally essential; such, for example, are the minute trace of malic acid, which will cause the larva of the wood boring organism Toredo to swim towards the wood which is to be the home of the mature animal (Harrington, *Biochem. J.*), or the infinitesimally small traces of substances of unknown character which Carrel has shown are produced by leucocytes growing in pure culture, and which appear necessary for the growth of fibroblasts (*J. Exp. Med.*, 1922, **36**, 385).

As far as I am aware, the next animal, higher in the evolutionary scale, to have been studied is the fruit fly, Drosophilia. Here we have clear evidence derived from the carefully planned experiments of Loeb and Northrup (*J. Biol. Chem.*, 1916, **27**, 309) and Harden and Bacot (*Biochem. J.*, 1922, **16**, 148), that the substance known as vitamin B is essential to the development and growth of the larvæ. Apparently the other vitamins (A and C) required by higher animals were not essential for this species.

Studies on the tadpole and frog have shown that whereas vitamin B is absolutely essential, there may be some dependence on vitamin A, but probably none on the antiscorbutic substance C (Emmett and Allen, *J. Biol. Chem.*, 1919, **38**, 325; Harden and Zilva, *Biochem. J.*, 1920, **14**, 262.) Fish require both A and B. When we study the birds we find dependence on both A and B factors marked, but the C substance of doubtful importance, whilst for the mammals not only are the former substances essential, and in some cases the antiscorbutic factor also, but there appears to be a dependence on other as yet less clearly defined factors, such as the antirachitic vitamin, and the substance necessary for reproduction discovered by the careful work of Evans and Bishop.

These few facts tend to support the view that in the progress of evolution the animal becomes more and more dependent on certain definite molecular structures synthesised by plant agency, and one recalls the words of Hopkins, spoken when, at a meeting of the Society of Public Analysts in London in 1906, he first announced the existence of the substances we now term vitamins, "The animal body is adjusted to live either on plant tissues or other animals, and these contain countless substances other than proteins, carbohydrates and fats. Physiological evolution, I believe, has made some of these wellnigh as essential as are the basal constituents of the diet."

I fear I have strayed somewhat from the usual path followed in discussions on vitamins, but I have done so deliberately in order to present an aspect of this subject which too frequently is lost sight of in the hope that it will stimulate much-needed work to resolve the factors which influence cell growth, particularly of the lower animals and plants, for we can scarcely hope to gain a knowledge of the development of the higher animals whilst we are almost wholly ignorant of those governing the growth of the unicellular organisms.

Having dealt with a physiological aspect of the vitamins I wish now to turn to discuss for a few moments what is known of their chemical nature, for we are at last beginning to gain some reliable information on this most important subject.

Vitamin A and the Antirachitic Vitamin D*

I propose to deal with these two substances together since we have recently obtained some evidence of their similarity on chemical grounds.

If one takes any natural substance containing one or both of these factors and subjects it to hydrolysis by means of a boiling alcoholic solution of caustic alkali under conditions preventing oxidative changes, one can extract both vitamins unchanged as regards physiological activity by light petroleum or ether.

The unsaponifiable matter prepared from cod liver oil, the usual raw material employed on account of its richness in both substances, represents a little under 1 per cent. of the original oil, but contains all the vitamin activity. Oxidation of this material rapidly destroys the growth-promoting substances A and rather more slowly the antirachitic factor D. By crystallisation from methyl alcohol at low temperature and by subsequent precipitation with digitoriss all the cholesterol present may be removed without affecting the vitamin activity of the residue, which is a red-brown oil corresponding to about 0·4 per cent. of the original cod liver oil. Attempts to isolate active fractions from this material are of little use, owing to the presence of considerable amounts of resinous substances formed during saponification. These may be removed by subjecting the material to distillation in superheated steam in an atmosphere of nitrogen. The purified material appears on analysis to consist very largely of unsaturated alcohols, possibly aliphatic but more probably allied to the hydroaromatic group. On fractional distillation in high vacuum four main fractions may be obtained :—

I. A small amount of an unsaturated alcohol of low-boiling point which, on hydrogenation, yields octyl alcohol.

II. B.p. 220–240°/2 mm. Consists chiefly of an unsaturated alcohol. B.p. approximately 225 at 2 mm. This fraction has as yet been examined very little, as it contains only traces of growth promoting or antirachitic activity.

III. B.p. 240–260°/2 mm.

IV. A fraction boiling between 260° and 300° at this pressure.

The growth-promoting substance A is definitely associated with fraction III, and, from some preliminary experiments which Miss Soames has recently carried out on my material, it appears to contain the antirachitic factor as well. Fraction III seems to consist almost entirely of an unsaturated alcohol, boiling approximately at 255°/2 mm., and containing two double bonds and one hydroxyl group and with molecular weight about 350. The evidence available does not yet enable us to say whether this alcohol is one of the vitamins, but I am inclined to the view that it is not, and that they are present as impurities. Even if this fraction were one of the vitamins a simple calculation makes clear how exceedingly small is the amount required by an animal in comparison with its ordinary foodstuffs. A rat of 100 g. eats daily about 3 g. of protein, 2 g. of fat, and 10 g. of carbohydrate. To supply the vitamins A and D it is only necessary to give the rat about 20 mg. of cod liver oil daily. This corresponds to approximately 0·2 mg. of unsaponifiable matter, and to 0·02 mg. of the active Fraction III. If the vitamins are, as we suspect, merely impurities present in that fraction the dose becomes vanishingly small. The vitamins will withstand the acetylation, and benzoylation, and apparently also the reduction of the unsaturated groupings of the alcohol, but oxidative changes destroy their activity. These preliminary researches exhausted the material at our disposal, but a large amount of unsaponifiable matter has now been prepared, and we are confident that the examination now in progress will give us a clearer indication of the chemical nature of vitamins A and D. At any rate, however hard our task, we have the satisfaction of knowing that we are dealing with clearly defined chemical units and not elusive substances such as the enzymes. The active fractions contain only carbon, hydrogen and oxygen. The crystalline material prepared by Takahashi (*Proc. Japan. Chem. Soc.*, 1922, 43, 828) and claimed by him to be the active substance, has been shown by us to be a crude mixture of the alcohols I have described. His view that the vitamin is an aldehyde is based on quite inadequate evidence, and although it would fit in with the ready destruction by oxidation, is not supported by the resistance of the active substances to vigorous hydrolysis with alkalis.

An attractive suggestion was that the active substances may be hydrocarbons of the type of spinacene found in certain fish liver oils. So far we have no evidence in support of this. Spinacene is itself inactive.

It might be mentioned in passing that the old sulphuric acid test for cod liver oil is invariably given by fractions containing the active substance, which lends support to the view, tentatively put forward by Drummond and Watson (*Analyst*, 1922, 47, 341) that the vitamins may be responsible. If this should prove true we will at last have one chemical test for the presence of a vitamin. No research is more urgent than that which will lead to replacement of the present laborious biological tests by quantitative chemical or physical methods of assay.

Vitamin B

No one of the vitamins has been more studied from the chemical side than this substance. In spite of this we are still in almost complete ignorance of its chemical nature. The most recent claim of isolation is that put forward by Bertrand and Seidell (*Bull. Soc. Chim. biol.*, 1923, 5, 794), who describe the separation of the active substance in

* The term vitamin D has been applied by Funk and Dubin (*loc. cit.*) to the substance which stimulates the growth of yeast. Since this substance appears to be not essential it is not well classified as a vitamin. The letter D can then be applied to the antirachitic factor which McCollum and his co-workers have satisfactorily differentiated from the growth-promoting vitamin A.

the form of a picrate, of which a daily dose of some milligrams will protect pigeons from beri-beri. The picrate can be separated by crystallisation from water into two picrates, melting at 202° and 160° respectively, the latter being the more active physiologically. Dr. Seidell informs me that he believes the active substance to be a pyrimidine. This will recall the similar belief held by Funk (*J. Physiol.*, 1911, 43, 395) and by Edie, Evans, Moore, Simpson and Webster (*Biochem. J.*, 1912, 6, 234), concerning the substances they isolated. Confirmation of the results of Bertrand and Seidell is urgently required.

Vitamin C

Curiously, this factor, although apparently of relatively simple character, has until recently received practically no attention from the hands of chemists. During the last year or two, however, the painstaking researches of Dr. Zilva at the Lister Institute have given us a good deal of valuable information regarding its properties.

He has shown that it is readily destroyed by oxidation when in solution reacting on the alkaline side of neutrality, and that its molecule is probably not much larger than that of a hexose. His attempt to isolate the active principles may be illustrated by the scheme outlined below (from *Biochem. J.*, 1914, 18, 632):—

1 litre lemon juice
80 g. of solid matter.
↓ precipitation with lime

80 g. citric acid, etc., inactive ← → 10 g. active material, largely sugar
↓ Fermentation

7·5 g sugar removed (inactive) ← → 2·5 g. active residue
↓ Alcohol pptn.

0·8 g. precipitate (inactive) ← → 1·7 g. active residue
↓ Basic lead acetate pptn.

1·4 g. inactive material not precipitated ← → 0·3 g. active substance pptd. by lead acetate.

The last stage he has reached, namely the basic lead acetate fraction, contains extremely small amounts of nitrogen and phosphorus, but possesses approximately the whole of the vitamin activity. It represents 0·03 per cent. of the original juice.

"*Bios.*"—I have intentionally omitted reference to the substance or substances which stimulate yeast-growths, since it is doubtful whether we should regard them as vitamins. They will, however, receive attention from other speakers to-day.

If more time were at my disposal I would direct your attention to other phases of present-day vitamin research, in particular to the important studies that are being made to ascertain the role of these deeply interesting substances in the life of the organisms. In this field much is being learnt about the extraordinary complexity of the processes of bone formation in the higher animals, and of the part played in those processes by the antirachitic vitamin D. One would also like to devote a short time to passing in review the extraordinary developments which have followed the recent application of knowledge regarding the vitamins to the practical problems of human nutrition and animal husbandry.

One cannot help feeling, however, that the most urgent problems are those concerning the chemical nature of the vitamins, for only when reasonably pure preparations of the active substances are available can we expect to gain a clear knowledge of their physiological action on the body.

THE LIMITATION OF STEAM CONSUMPTION IN CHEMICAL WORKS

By C. FRED HOLMBOE, D.Sc., Christiania

During recent years a great deal of work has been done to improve and control the efficiency of boiler plants, not only in connexion with steam generation for the production of power, but also with the generation of steam used for heating, drying and similar purposes in the chemical and kindred industries. Special requirements as to steam temperature, pressure, fluctuations in the steam consumption and other points, have also been thoroughly studied in order to make it possible to design a boiler plant which in each individual case will give the best economical result.

With a well-designed boiler plant with stokers, economisers and superheaters—if necessary—a total efficiency of 75 to 80 per cent. may be obtained in continuous work by using average good coal. In order to control the efficiency of the boiler plant and the working of each individual boiler the installation of automatic coal-weighing machines, water meters, differential draught indicators, carbon dioxide and pressure recorders, and temperature recorders is essential.

Particularly in big works where a large amount of steam is used in many different processes, it is necessary, in order to arrive at a good economy, not only to have an up-to-date boiler plant, but also to see that steam is not wasted. On this side of the question I think that a great deal still has to be done before satisfactory conditions are arrived at in most works.

In the steam meter of to-day, which in accordance with my experience is very reliable for tests which require an accuracy within a couple of units per cent., we have an instrument of great utility for investigating the steam consumption necessary for plants and apparatus.

It is obvious that a man in charge of a plant is at a loss as far as the steam-consumption goes when he has no other means of control than a steam valve,

and he may be using considerably more steam than actually required without knowing it. On the other hand, it would be too expensive to put a steam meter on to every apparatus to check the flow of the steam, as it generally is quite sufficient for controlling the cost of production to have one meter for each department.

I have, therefore, tried another way in order to economise the steam, and as this in practical use has proved to give a very satisfactory result without complicating the plant, I shall here shortly describe the methods adopted.

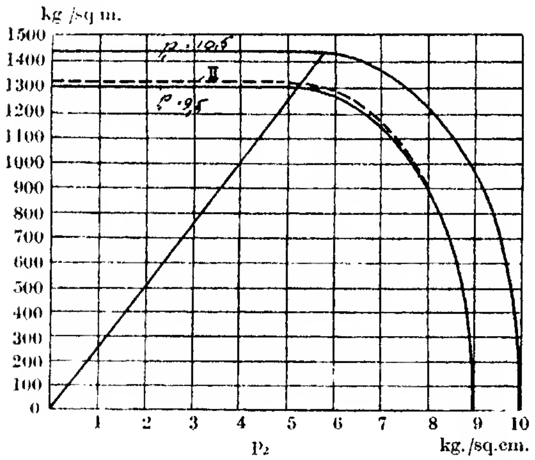

FIG. 1

If steam is used in an apparatus either under atmospheric pressure or vacuum by blowing the steam through a nozzle or perforated coil into the chemicals to be treated, the steam consumption is only controlled by the opening of the valve, and it is well known that the valve at times is opened more than is actually required for the process. The steam pipe leading to the apparatus is, as a rule, calculated for a velocity of the steam ranging from 30 to 60 m./sec. depending upon the maximum drop in steam pressure, but this speed can often be increased to 80–100 m./sec. and more, without the drop in pressure increasing to an extent which interferes with the carrying out of the process. This also applies to plant in which the steam is used for indirect heating in jackets and coils, particularly when, as often happens, the steam trap behind the jacket or coil is left with an open by-pass, or the heating surface is bigger than required.

In order to limit the flow of steam to a maximum figure, which has to be ascertained by calculation or experiments, I have arranged a nozzle between the regulation valve and the apparatus (or a series of apparatus) which automatically limits the flow of steam to the maximum as long as the steam pressure actually required is less than a critical pressure p_m which is about 57 per cent. of the initial pressure p_1. This can be applied to a great number of cases where steam is used direct or indirect and the process only requires the heat of the steam.

The critical pressure :—

$$p_m = p_1\left(\frac{2}{k+1}\right)^{\frac{k}{k-1}}$$

In this formula is k the exponent for polytropic expansion :—

$$p.v^k = \text{Constant}.$$

For dry saturated steam $k = 1.135$, and $p_m = 0.5744 p_1$.

The velocity of the steam through a cylindrical nozzle under these conditions and without taking the friction loss into account is

$$c_0 = \sqrt{2g\frac{k}{k+1}\cdot p_1 v_1}$$

With the initial pressure and volume expressed in kg./sq. cm. and cb. m./kg. Then for saturated steam with $k = 1.135$

$$c_0 = 323\sqrt{p_1 v_1}.$$

The amount of steam passing through the nozzle with Fm^2 opening is in kg. per sec. :—

$$P = F\sqrt{2g\frac{k}{k-1}\,\frac{p_1}{v_1}\,\frac{k-1}{k+1}\left(\frac{2}{k+1}\right)^{\frac{2}{k-1}}}$$

or for $k = 1.135$,

$$P = F.199\sqrt{\frac{p_1}{v_1}}$$

The actual velocity, $C = \phi . C_0$

ϕ is the coefficient of friction which, for properly designed nozzles, is about 0·97—0·98.

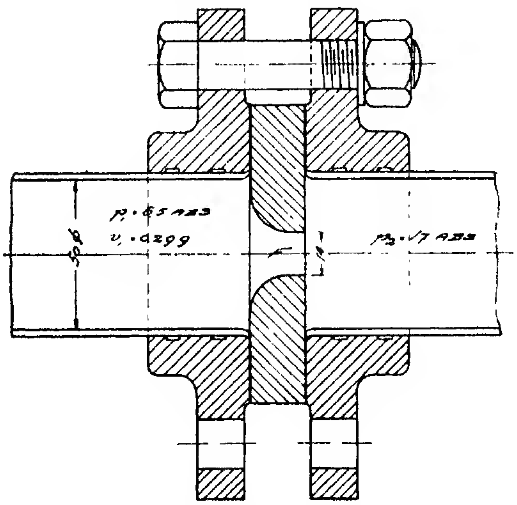

FIG. 2

Fig. 1 gives some results of tests carried out at $p = 9{\cdot}5$, and $10{\cdot}5$ kg./sq. cm with a nozzle 5·4 mm. diameter. The ordinate gives the weight of steam passing through the nozzle in kg. per sq./m. per sec. The curve II is the theoretical weight calculated. It will be noted from these curves that the friction in a well-designed nozzle has very little influence.

Fig. 2 shows the nozzle 1 arranged in a 2 in. pipe leading to fourteen open coils in order to limit the maximum steam supply to about 500 kg. per hour, with $p_1 = 6{\cdot}5$ kg./sq.cm. and $p_2 = 1{\cdot}7$ kg./sq.cm. absolute pressure.

The maximum velocity of the steam (dry saturated) in the nozzle is about 440 m/sec. or 1430 feet per sec.

The influence of the nozzles on the steam consumption in the department is shown in the diagrams, Fig. 3. A gives the steam required without the nozzles on a double shift of 16 hours on June 12, 1923, with 10 coils, and B the steam required on June 12, 1924, with 14 coils after the nozzles were fitted and on an 8 hours shift. The production in the department was the same in both cases.

The saving in steam calculated from the diagrams (Fig. 3) was 56·5 per cent. and the total saving over one month 44·7 per cent., equal to £670 per year. The cost of the nozzles was about £3.

After having obtained this satisfactory result in one department I introduced the same arrangement for limiting the maximum steam consumption in all departments where it could be used with advantage.

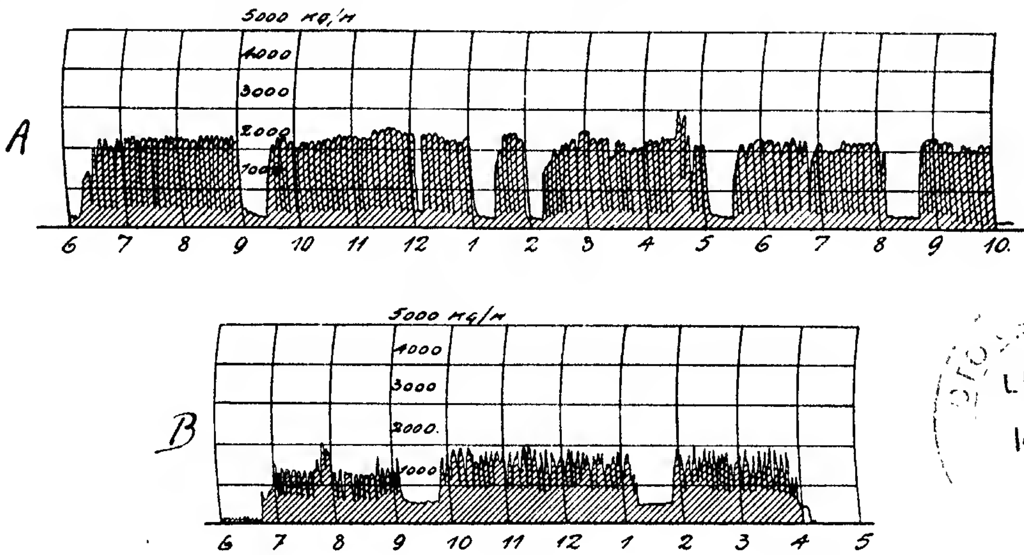

Fig. 3

In order to find the right size of the nozzles we studied the curves of the main steam meter of the department and calculated the nozzle or nozzles to give about 60 per cent. of the maximum indicated by the meter. In some cases it was necessary to give the nozzle a larger diameter, when experience showed that the work could not be satisfactorily carried out because the nozzle did not give sufficient steam. In such cases we increased the diameter step by step, by 0·5 to 1 mm. at a time, in order to avoid getting too big nozzles. The result in every case was a reduction in the amount of steam used.

We have also adopted, with good results, the same system to limit the quantity of cooling-water used in coolers with coils or jackets, as it was found that when the cooling water could leave the cooler with a temperature of, say, 30 to 35° C. it actually ran off at 15 to 20° C., which, of course, meant an extravagant use of water, and power for the pump supplying the water.

JOINT COMMITTEE FOR THE STANDARDISATION OF SCIENTIFIC GLASSWARE

Report on Units of Volume*

The Committee have given much careful consideration to the question of units of volume, and as a result of their deliberations they unanimously recommend:—

That the recognised international metric units—the *litre* (*l*) and *millilitre* or thousandth part of the litre (*ml*)—shall be used as the standard units of volume, and that standard volumetric glassware shall be graduated in terms of these units and marked *ml* instead of *c.c.*

In making this recommendation, the Committee have had in mind the great advantages to be gained by the general use of a uniform system which has been recommended by many scientific bodies, and is at present already extensively used, notably in America. The substitution of the millilitre for the cubic centimetre involves no practical difficulties, as the two units differ only very slightly in magnitude. The difference in capacity between a 1000 c.c. and a 1000 ml. flask is, for example, only one-seventh of the permissible error on a standard 1000 ml. flask.

As in the course of the discussion, it became evident that some chemists still prefer to use Mohr's system of units, and would be unwilling at present to change their existing practice the Committee has felt it desirable to couple with the above recommendation certain proposals designed to remove the confusion at present existing between the two systems of units. These are :—

(1) That the unit of volume on Mohr's system shall

* Slightly abridged. The full pamphlet can be obtained, price 6d. post free, from the Secretary to the Joint Committee, Mr. G. W. Marlow, B.Sc., 30, Russell Square, London W.C. 1.

in future be designated "G.W.A.," and that these letters shall be marked on all volumetric glass vessels graduated on the basis of Mohr's system, and shall be used by chemists when reporting results obtained by the use of such vessels.

(2) That the "G.W.A." unit shall be defined thus:—

1000 G.W.A. = 1002 ml.

These additional recommendations will enable the two systems to be used side by side with a minimum of inconvenience during the transitional period which the Committee realise must precede the universal adoption of the litre and millilitre for general chemical work.

The Committee understands that in view of the above recommendations the National Physical Laboratory will accept for test† vessels graduated on the basis of G.W.A. units, and clearly marked to indicate this, and will place a distinctive mark on approved vessels graduated on this system, but not the Laboratory monogram *NP*, which will be reserved for vessels graduated in millilitres.

Information relating to the two systems of units, and the reasons underlying the above recommendations are given in the following notes.

Metric Units of Volume

The volume of a body of simple geometrical shape can readily be calculated from the linear dimensions of the body. Hence, once the unit of length has been decided upon, the unit of volume should theoretically be defined in terms of the unit of length. The volume of a cube each of whose sides is of unit length becomes automatically the unit of volume; such a definition by its logical simplicity makes an instant appeal to the mind, and it is therefore natural to find in common use such units as the cubic centimetre and the cubic foot, based on the corresponding units of length.

Volumetric measurements, however, are most extensively used when dealing with fluids, and hollow vessels of known capacity have long been used for measuring volumes of liquid. But whereas it is extremely difficult to determine accurately the capacity of a hollow vessel from measurements of its internal dimensions, the weight of liquid required to fill a vessel can, on the contrary, be determined easily and with a high degree of precision. Hence units of volume have come into use which are not defined in terms of the units of length, but as the volumes occupied by specified weights of a particular liquid—usually water. The gallon and the litre are units of this kind.

Two distinct types of units of volume have thus come into general use. Sooner or later under any system the necessity arises of determining the relation between the two types of units, of determining, for example, the number of gallons in a cubic foot. In the older systems of units the two types of units of volume were defined independently of each other, and as a result no simple numerical relation exists between them. The number of gallons in a cubic foot, for example, is not represented by a simple whole number.

One of the objects of the founders of the Metric System was to secure a simple numerical relation between the two types of units of volume. It was intended to achieve this by defining the unit of mass, the kilogram, as the mass of a quantity of water which at its temperature of maximum density occupied a cubic decimetre. The unit of volume, the litre, could then be defined indifferently either as a cubic decimetre or as the space occupied by a kilogram of water at its temperature of maximum density.

A cubic decimetre of water is, however, manifestly unsuitable for practical use as a standard weight. To give practical effect to the system it was necessary to make a standard kilogram weight whose mass should be in accordance with the definition laid down. A standard kilogram weight—the "Kilogramme des Archives"—was prepared with great care and skill at the end of the eighteenth century, but during the nineteenth century distrust in the accuracy of the work arose. Consequently in 1872 the *Commission Internationale du Metre* discussed the matter fully in all its bearings and decided that the International Kilogram should be deduced from the Kilogram des Archives in its actual state. The original definition of the kilogram was thus abandoned, and the kilogram was re-defined as the mass of a particular standard weight.

The definition of the litre was subsequently revised* in conformity with this change, and the accepted definition at the present time is:—

"The unit volume for determinations of high precision is the volume occupied by a mass of one kilogram of pure water at its temperature of maximum density and under normal atmospheric pressure†; this volume is termed the litre."

It is important to observe that the definition of the litre is now absolutely independent of the metric units of length. The cubic centimetre, on the other hand, being simply the volume of a cube whose edges are one centimetre long, is completely defined without any reference to the volume of a mass of water. Thus no direct relation between the litre and the cubic centimetre results from the definitions of these units. This relation can only be obtained by direct experimental determination, and the most accurate determination available is that carried out at the Bureau International des Poids et Mesures. M. Benoit‡ in his summary of the work gives as the most probably value

1 litre=1000·027 c.c.

and states that the uncertainty of this value probably does not exceed one unit in the last decimal place.

The difference between the cubic centimetre and the millilitre is so small as to be negligible for ordinary volumetric glassware. The term "cubic centimetre" has, however, been misapplied by the

† A pamphlet giving details of the tests on volumetric glassware carried out at the National Physical Laboratory may be obtained free of charge on application to The Director, The National Physical Laboretory, Teddington, Middlesex.

* *Trav. et Mem.*, 1920, 12.

† Water is slightly compressible, and hence the volume of any given quantity of water varies slightly with the pressure to which it is subjected. Hence, to be precise the definition of the litre must state the pressure to which the water is to be subjected.

‡ *Trav. et Mem.*, 1910, 14.

users of Mohr's system to denote the volume of a quantity of water having an apparent weight in air of 1 gram. A flask which contains an amount of water weighing 1000 grams in air has a capacity of almost exactly 1002 c.c. To speak of such a flask as a 1000 c.c. flask is clearly inadmissible. Volumetric glassware, manufactured by the leading British firms, and marked "c.c.," may safely be relied upon as having been calibrated on the basis of the cubic centimetre. Volumetric glassware of foreign manufacture similarly marked "c.c.," may have been calibrated in terms of either the cubic centimetre or grammes of water.

In view of this confusion in the use of the term cubic centimetre, and of the fact that the cubic centimetre is not exactly one thousandth part of a litre, and further, because the mass of water which occupies 1 c.c. under definitely specified conditions cannot be directly derived from the accepted definition of the litre, the Committee adopted the recommendation given above.

The acceptance of this recommendation by chemists and manufacturers of volumetric glassware would bring the practice in this country into line with that in other countries, notably America, and would give effect to the recommendation of numerous scientific bodies that the litre, as defined above, should be exclusively used as the unit of volume in all scientific work. The publication of all results in terms of millilitres would secure a uniformity which is at present lacking, and remove the uncertainty due to the term cubic centimetre being used sometimes correctly, sometimes as equivalent to the millilitre, and sometimes as the space occupied, under conditions not generally well defined, by a quantity of water which has an apparent weight in air of one gram.

Mohr's System

According to Mohr's original proposal a "litre" flask would be adjusted so that when filled with water at 17·5° C. it would contain an amount of water which, when weighed in air against brass weights, had an apparent weight of 1000 grams. Such a flask would contain almost exactly 1002 c.c. The term cubic centimetre was misapplied to the thousandth part of this volume. This misuse of both the terms litre and cubic centimetre still persists.

Some chemists still maintain that it is more convenient in practice to use as a unit of volume the space occupied by a quantity of water which has an apparent weight of 1 gram in air at ordinary room temperature.

To avoid confusion resulting from the use of the terms "litre" and "cubic centimetre" in connexion with such units, the Committee recommends (see (1),) that the letters "G.W.A."—a mnemonical abbreviation for "grams of water in air"—shall be used in describing such units.

It is further necessary that an exact definition of the "G.W.A." unit be adopted.

A quantity of water which weighs 1000 grams in air of density 0·0012 g./ml. when weighed against brass weights of density 8·4 g./ml. occupies a volume of 1002·021 ml. at 60° F. This volume differs from 1002 ml. by only two parts in a hundred thousand, which is negligibly small in comparison with the tolerances allowed on volumetric glassware, and the accuracy attainable in the ordinary use of such glassware. Hence the committee on grounds both of convenience and precision has adopted the definition given in recommendation (2), namely :—

1000 G.W.A. = 1002 ml.

This relation defines the G.W.A. unit in a simple and accurate manner, and at the same time gives it a value which differs only by a negligible amount from the volume occupied at room temperature (60° F.) by a quantity of water which has an apparent weight of 1 g. when weighed in air against brass weights.

The above definition enables conversion from millilitres to G.W.A. units and *vice versa* to be easily made, and will enable the two units to be used side by side without confusion during the transitional period which must elapse before the universal adoption of the litre and millilitre is obtained in this country.

August, 1924

ACADÉMIE DES SCIENCES

On August 11, Monsieur M. Vinogradski described his work on the microscopic analysis of arable soild and on August 18, Prof. Haller read a paper on the decomposition of chloroform. On August 25 M. Leconte communicated a paper by E. Picard on the solubility of tannins in relation to extraction. The work shows that to extract the different tannins completely from vegetable tissues, different solvents have to be used

FORTHCOMING EVENTS

Sept. 15. British Empire Exhibition. Conferences of Engineering Societies, to be held in Conference Hall No. 4, at 10.30 a.m. Short papers on various Engineering Subjects will be read and discussed.

Sept. 18 and 19. The Ceramic Society. Refractory Materials Section Meeting, in Conference Hall No. 4, British Empire Exhibition, Wembley.

The following papers will be read :—"A Comparison of Gas and Coke Fired Drying Stoves, together with a Description of the Construction and Operation of the Huttenes Coke-Fired Air-Blown Furnace," by T. W. Barley; "Some Properties of Clay Silomanite Mixtures," by J. W. Cobb and H. S. Houldsworth, "The Influence of Exposure on the Chemical and Physical Properties of Certain Fireclays," by W. Hugill and W. J. Rees; "On the Action of Heat on Kaolinite and Kolinitic Clays" (Communicated Paper), by W. Vernadsky; "Alumina-Silica Minerals in Firebricks," by W. J. Rees; "The Action of Heat on Kaolinite and other Clays," Part II, by J. W. Mellor and A. Scott; "The Origin of the Austrian Magnesite Deposits," by A. Scott; "X-ray Investigation of Clays and other Ceramic Substances. Researches into the Application and Practical Value of the Method," by A. Hadding; "Note on the Storage of Silica Refractories," by W. J. Rees; "The True Specific Gravity and After Expansion of Lime-bonded Silica Bricks," by W. J. Rees; "A Rapid Method for the Determination of True (or Powder) Specific Gravity," by W. Hugill and W. J. Rees.

SOCIETY OF CHEMICAL INDUSTRY

CHEMICAL INDUSTRY DINNER

The Autumn Dinner, which will be under the auspices of the Society of Chemical Industry and the Chemical Industry Club, will be held in the Edward VII Rooms of the Hotel Victoria, Northumberland Avenue, London, W.C. 2, on Friday, November 14, at 7 for 7.30 p.m., and will be presided over by Mr W. J. U. Woolcock, C.B.E., President of the Society.

A circular letter with further particulars and a form of application for tickets has been sent out to the members.

BACK NUMBERS OF JOURNAL

The General Secretary will be glad to hear from Members or Subscribers who have copies of the *Journal* for January 5, 1923, or January 4, 1924, that they are willing to dispose of to the Society.

BRISTOL SECTION, SESSION 1924-25

The meetings are held at 7.30 p.m. in the Chemical Department of the University (Woodland Road), and will be held in each case jointly with the local section of the Institute of Chemistry. On October 2 the session opens with an address by H. T. Ringrose, on "Combustion Control in Boiler Houses." E. J. Holmyard will speak on "The Present Position of the Geber Problem" on November 6, and on December 4 W. E. Fearnsides will present a paper on "Some International Aspects of the Dye Industry."

The meetings in 1925 will commence on January 8 and will be held jointly with the Chemical Society, the title of the address to be announced later. On February 5, P. G. J. Gueterbock will speak on "Tin," and on March 5 a General Meeting for the election of officers will take place, the Chairman's address being on "Paint and Paint Making."

It is proposed to hold the Annual Dinner jointly with the Institute of Chemistry and the Chemical Society. The date will be announced later. Visits to works are also being arranged.

SYDNEY (NEW SOUTH WALES) SECTION

The Secretary of the Section reports that an additional meeting was held in July, and that it is hoped to hold one regularly every month, as there is plenty of matter to discuss.

At the meeting on July 23, a discussion took place upon a previous lecture on Chilean Nitrates.

The Section has made an arrangement with a leading firm of technical booksellers by which the most recent publications are lent to be displayed at the evening meetings, and as quite a number of members living over a scattered area have no chance of seeing those books during the day, the plan appears to be thoroughly appreciated.

The practice of members holding a little dinner before each meeting has also been adopted.

It is proposed to follow the example of many of the Home and Canadian Sections of the Society in admitting Associates to the Section. In this way it is hoped to attract to the meetings students who will ultimately become members of the Society.

CORRESPONDENCE

JOINT COMMITTEE FOR THE STANDARDISATION OF SCIENTIFIC GLASSWARE

Sir,—The Joint Committee for the Standardisation of Scientific Glassware is a committee, working under the *ægis* of the Institute of Chemistry, having members representing the users, manufacturers, dealers and Government Departments interested in scientific glassware. The Committee was formed to consider questions relating to the standardisation of scientific glassware. A list of members is given in the report on Units of Volume.

The Committee have given very careful consideration to the fundamental question of units of volume, and desire to call your attention to the enclosed report* which embodies their recommendations. It is hoped that these recommendations will be accepted generally by those responsible for the instruction of students.

A further question to which the Committee have devoted considerable time is the accuracy of volumetric glassware. It was considered that two grades of volumetric glassware, and two only, are desirable and necessary, namely :—

Class A, or Standard Apparatus

This must be of the highest accuracy reasonably attainable, of best quality materials and workmanship, and each vessel should be tested and approved by an impartial institution before being accepted as of standard grade. The National Physical Laboratory is the appropriate institution in this country for carrying out the tests.

Class B, or Commercial Grade Apparatus

This is a cheaper quality apparatus for general use, but guaranteed by the manufacturer to conform with definitely recognised limits of accuracy and other necessary requirements.

The specification for Class B apparatus must necessarily be less stringent than for Class A apparatus and should, for the sake of economy, make the minimum demands on the manufacturer consistent with satisfactory service for work in which commercial grade apparatus may reasonably be employed.

The Committee consider that the regulations for the Class A Tests and Class B Tests on volumetric glassware laid down by the National Physical Laboratory form a satisfactory basis for the two grades of apparatus. These regulations are contained in a Laboratory test pamphlet † which has recently been revised and the National Physical Laboratory has afforded the Committee the fullest opportunity of co-operating in the revision.

The manufacturers' representatives on the Committee have agreed to supply, in addition to standard Class A apparatus tested at the National Physical Laboratory, Class B apparatus guaranteed by themselves. They will undertake to replace any article so guaranteed and found not to fulfil the requirements of the National Physical Laboratory regulations for Class B apparatus, with apparatus tested at the National Physical Laboratory, and bearing the Laboratory mark signifying that it complies with the

* See p. 913. † See p. 919

Class B requirements. No charge will be made by the manufacturers for any such replacements.

The sale, purchase or use of volumetric apparatus inferior in quality to Class B apparatus is detrimental to the best interests of all concerned, and the Committee hopes to see the elimination of all such inferior apparatus. Candidates for examination, in particular, should be entitled to put confidence in the accuracy of the apparatus with which they are provided, and if they are given inferior apparatus they are liable to suffer grave injustice in the assessment of their work by reason of errors which lie outside the scope of their own manipulation.

The success of the Committee's efforts must ultimately depend upon the action taken by purchasers of volumetric glassware. The Committee would therefore urge upon educational authorities and institutions the desirability, when they are purchasing volumetric glassware, of specifying either:—

(*a*) That the apparatus must have passed the Class A tests at the National Physical Laboratory and be accompanied with a Laboratory certificate.

or (*b*) That the apparatus must have passed the Class A tests at the National Physical Laboratory—certificate of corrections not required.

or (*c*) That the apparatus must have passed the Class B tests at the National Physical Laboratory.

or (*d*) That the apparatus must be guaranteed by the vendor to comply with the National Physical Laboratory regulations for Class B tests.

The alternative adopted will, of course, depend upon the purpose for which the apparatus is required.

The Joint Committee fully realise that for elementary teaching purposes economy in initial outlay on apparatus is a necessity. They feel confident, however, that subject to a satisfactory demand, manufacturers will be able to supply guaranteed Class B apparatus at prices consistent with reasonable economy. They also believe that it will be found ultimately more economical for advanced work and research, for which apparatus of doubtful accuracy cannot be tolerated and calibration is essential, to purchase tested Class A apparatus rather than to purchase untested apparatus and invariably carry out a calibration after purchase.

Finally, the Committee would urge most strongly that under no circumstances should orders for volumetric glassware be placed without definite limits of error being specified, as failure to do so tends to encourage the production of inferior apparatus in which quality and accuracy are unduly sacrificed for cheapness. Some of the cheaper calibrated apparatus is known to be so inaccurate as to lead to grave errors, even in the most simple determinations. The Committee believe it will be found that the simplest and most satisfactory way of specifying limits will be to refer to the National Physical Laboratory tests as indicated previously.—I am, Sir, etc.,

G. W. Marlow

Secretary to the Joint Committee

August, 1924

OPTICAL ACTIVITY AND POLARITY THEORIES

Sir,—Much of the criticism passed by Dr. Boyd in your issue of August 22 upon some suggestions of mine relating to optical activity and the polarity of groups (*J.C.S.*, 1924, **125**, 1121) is based on misunderstanding which would probably disappear on a more careful reading of the paper in question.

It is true that there is as yet no agreement between chemists as to the exact meaning of the word polarity used in connexion with atoms and groups, and these differences are rightly emphasised by Dr. Boyd. But from the order in which he raises the points in his letter he appears under the impression that my derivation of a polar series from inductive capacities was purely by way of confirmation to that derived from benzene substitution and acidic strengths. A further reference to the paper will, I think, convince him that the whole argument is based on certain conclusions of Sir J. J. Thomson (*Phil. Mag.*, 1923, vi, **46**, 497), by means of which the relative polarity of *simple* substituents may be derived from inductive capacities.

Sir J. J. Thomson compares the introduction of a substituent into a hydrocarbon chain to that of an electric doublet of variable sign and strength. In the case of a *methyl* or *hydroxyl* group, for example, the doublet is arranged with its positive end at the electron linking the group to the parent molecule and its *negative* end free. On the other hand, a *nitro* or *carboxyl* group is represented as a doublet with its negative end towards the parent molecule and its *positive* end free. In this manner substituents are divided into two classes of opposite polarity, *e.g.*, NO_2, COOH, CN, and H of the one type, and CH_3, the halogens and OH of the other. This classification is in complete agreement with that adopted by the exponents of induced alternate polarity. An induced alternate polarity, however, is not necessarily the only or even the chief result of the presence of a substituent of high polar character. Moreover, induced alternate polarity is presumably transmitted through the chain of atoms, whereas the polar influence of a substituent may, as suggested by Sir J. J. Thomson, be due to the electrical changes around as well as within the molecule.

Dr. Boyd fails to understand how a series such as NO_2, CN, H, CH_3, Cl, is obtained from inductive capacities. Sir J. J. Thomson states that the change in inductive capacity following on substitution is a measure of the strength of the doublet introduced. Hence the relative effect produced by different substituents when attached to hydrogen or hydrocarbon radicals, which are themselves of low inductive power, provides a means of estimating their relative polarity. With a comparatively non-polar compound such as a hydrocarbon the inductive capacity is raised by positive and negative substituents alike, although the electrostatic moment of the derivative formed in the one case will be of the opposite orientation to that formed in the other. For this reason the sign to be attached to the substituent must be determined in some other manner, and the general polar series NO_2, CN, Cl, CH_3, H

which represents relative magnitudes irrespective of sign, must be rearranged to NO_2, CN, H, CH_3, Cl, indicating a change from high positive polarity through neutral to high negative polarity.

In its final form the series closely represents the relative effect of the substituents on benzene substitution and the optical activity of certain *d*-amyl and *l*-menthyl derivatives.

The derivation of this series from inductive capacities is described in the above paper, followed by the statement that approximately the same sequence can be obtained *in a similar manner* from the dissociation constants of acetic or benzoic acids. Dr. Boyd has evidently overlooked the words here italicised.

Again, Dr. Boyd first and quite unjustifiably assumes that when I refer to the polarity of a group I am thinking of the induced polar influence of this group, and then applies the principle of induced alternate polarities to examples quoted in my paper in order to show that the induced effects bear no relation to the optical activity. His conclusion at all events is in agreement with the facts as we know them, but it does not affect my argument. I have in no way attempted to correlate optical activity with induced alternate polarity. According to Sir J. J. Thomson (*loc. cit.*) the intense electric field due to the introduction of a radical such as Cl or OH will bring about a great change in the distribution of electrical forces in and around the molecule. The change due to a negative substituent must therefore be in the opposite direction to that due to a positive one.

Finally Dr. Boyd writes that I use the term polarity in a sense differing from either of the meanings hitherto attached to it. In this I think he is confusing polarity with the effects supposed to be consequent upon polarity. The suggestions under discussion have yet to be tested in the light of further experimental evidence, but they require no new conception of polarity. Rather do they allow two of the meanings at present in use to be reduced to one.—I am, Sir, etc., H. G. Rule

Edinburgh University

PERSONAL AND OTHER ITEMS

At the luncheon held by the Institute of Metals in the Connaught Rooms on September 9, Mr. W. J. U. Woolcock, C.B.E., President of the Society of Chemical Industry, responded to the toast of "Our Guests."

On September 13, Dr. E. F. Armstrong, F.R.S., will commence his two months' tour in America, where he will travel extensively in the Eastern States. On October 17 he will address a joint meeting of several chemical organisations in New York. He will also lecture at Yale, Princetown and Philadelphia. His subject on October 17 will be "The Fats from Many Aspects."

Prof. F. Soddy, F.R.S., has been elected a foreign member of the Reale Accademia Nazionale dei Lincei of Rome.

Mr. Roscoe Brunner, chairman of Brunner, Mond and Co., Ltd., and Captain the Hon. William Hulme-Lever, a director of Lever Brothers, Ltd., have been appointed Deputy Lieutenants for the county of Chester.

On September 6, a bronze tablet commemorating the centenary of the discovery of Portland cement by Joseph Aspdin was unveiled in the entrance of the Leeds Town Hall, by a delegation of the Portland Cement Company of America, the donor of the memorial.

Dr. W. J. Huff has been appointed to the chair of gas engineering established at the John Hopkins University, with funds provided by the Southern Gas Association.

August 16 was the twenty-fifth anniversary of the death of Bunsen (1811—1899).

The death is announced of Dr. Adolf Römer, a pupil of Lothar Meyer, who, after working some time with the Badische Co., did valuable work on dye and tannin extracts, particularly in connexion with the use of mangrove bark, work described at the seventh International Congress of Applied Chemistry in London.

Alex. E. Macrae, B.Sc., chemical and metallurgical examiner in the Canadian Patent Office, has retired. He has established himself, in Ottawa, as a Patent Solicitor. Mr. Macrae is Secretary of the Ottawa Section of Society of Chemical Industry.

Prof. C. E. Munroe, chairman of the Committee on explosives investigations of the U.S. National Research Council, has been elected an honorary fellow of the American Institute of Chemists. The only other honorary fellow of the American Institute is Prof. C. F. Chandler.

Dr. Ellwood Hendrick has been appointed curator of the Chandler Chemical Museum at Columbia University. The museum, due to Prof. C. F. Chandler, includes the raw and finished products of manufacture of most of the important industries. Amongst the exhibits are dyestuffs and intermediates, many inorganic and organic chemicals, oils and fats and their products, ceramic and metallurgical products as well as natural products, photographic products and processes, and many other products of industry.

From Italy the death is announced of Prof. F. Martinotti, Director of the Royal Experimental Station for Oenology at Asti. Prof Martinotti had carried out investigations on the cultivation of vines, insecticides, the use of refrigeration in wine-making, and the modern technique for making sparkling wines is largely due to him His last work bore on the production of non-alcoholic sparkling wines, a problem which he had apparently solved.

Dr. E. Galli, whose death is announced, was director of the municipal chemical laboratory of Milan and had founded a successful school of baking.

Tests on Volumetric Glassware

The Metrology Department of the National Physical Laboratory has issued a revised edition of the pamphlet describing tests on volumetric glassware, including both Class A and Class B tests. Descriptions are given of tho general conditions and methods of tests, details of regulations and tolerances for various apparatus and regulations governing Class B tests, and for vessels graduated in "G.W.A." units, together with a list of fees chargeable. Any member of the Society of Chemical Industry who desires a copy may obtain one free of charge, on application to the Director of the National Physical Laboratory, Teddington, Middlesex.

Phosphatic Fertilisers in Germany

According to the "Deutsche Berwerkszeitung," the consumption of phosphatic fertilisers during the current agricultural year has decreased by 65 per cent. compared with the previous year. During the period May 1—December 31, 1923, only 82,000 tons was applied, whereas 336,000 t. was used during the same period of 1913. Prices are much higher than during the war.

Copper Consumption in Szechwan (China)

The amount of copper consumed annually by the Chengtu Mint, the Chungking Mint and the Chengtu Arsenal is 12,000 t., either in the coinage of coppers or in the manufacture of alloys for arms and ammunition. The province itself produces about 600 t. a year, and imports about 1200 t. from the neighbouring province of Yunnan. For the remainder Szechwan province relies on foreign importations, chiefly from the United States. As the province is not politically at rest, only about 8000 t. is now consumed, mostly for the coinage of copper coins.

New Soap Works in Chungking

A new soap works known as the Sun Soap Manufacturing Co has just been opened in the immediate neighbourhood of Chungking. A wholesale department of the same company will also be opened up in the Chungking Bazaar. The company has turned out over twelve kinds of soaps.

Bromine Production in Germany

The output of bromine in Germany in 1923 amounted to 1140 t., compared with 1280 t. in 1922 and 460 t. in 1921. This increase in 1922 and 1923 is attributed, in part, to the greater consumption of the photographic industry.

A Giant Coke-Oven Plant

The Carnegie Steel Company has just completed what is said to be the largest by-product coke plant in the world at its Clairton, Pa., works. It has been in course of construction for about two years, and supplements the original by-product coke plant at this place. The new plant consists of 366 ovens, arranged in six batteries of 61 ovens each. It has a daily capacity for carbonising 8500 t. of coal, producing in this period a total of 6000 t. of coke, 55 million cb. ft. of gas, 90,000 gall. of tar, 215,000 lb. of ammonium sulphate and 25,000 gall. of benzol products. It is proposed to develop the new works to their maximum capacity as soon as the conditions warrant.—(*Chem. and Met. Eng.*, *July* 14, 1924.)

REVIEWS

Drying by Means of Air and Steam. By E. Hausbrand. Third revised English edition. Pp. viii+77. London: Scott, Greenwood and Son, 1924. Price 6s.

Previous editions of this standard work have made it familiar to most of those who deal with this type of problem. The main difference in the present edition is the addition of an appendix containing various diagrams relating English and metric units. This is a distinct help, though it would be more so if it included a few compound conversions such as "kilos per cubic metre" to "lbs. per cubic foot," etc. Also in Tables 1 and 3 it would be helpful if there were a blank space at every sixth line, as the eye is apt to lose its way among such closely packed figures.

There is no revision of any consequence in the text itself. The initial chapters deal with the calculation of the amount of vapour in a kilo of air at various temperatures and pressures, and the results are tabulated and also shown on a chart. The method is then extended to deal with the weight and volume of air, and expenditure of heat to evaporate 100 kilos of water, under various conditions of temperature, pressure and final saturations. The tables of volumes, weights and pressures of saturated vapour and the accompanying dry air are very convenient. Drying by means of superheated steam without air is discussed, and also the necessary dimensions of heating surfaces and drying rooms.

The calculations are clear and readily followed, though the formulæ used for ascertaining the latent heat of evaporation, etc., may appeal less to some than, say, those employed in compiling the Callendar steam tables. Some of the assumptions might be called a little into question: for instance, that a very slightly superheated vapour behaves as a permanent gas (p. 19), but may be justified on the ground of the complication which would be introduced by a more exact consideration, which would lead to substantially similar results in practically all cases.

The book is indispensable to all students of the subject, and even the experts will find a useful guide in the tables and charts.

Chemisch-Technische Vorschriften. Part IV.—Dungemittel (Sprengstoffe), Futtermittel, Lebensmittel. By Dr. O. Lange. Third edition, completely revised and enlarged. Pp. 21+750. Leipzig: O. Spamer, 1924. Price: Paper 45 goldmarks, bound 50 gm.

This is volume four of "a handbook of special chemical technology, especially for chemical factories and related technical industries, containing recipes from all branches of chemical technology and comprehensive references to the literature." It comprises 716 large closely printed pages of matter, and 33 three-column small type pages of index.

A brief summary of the chief contents will give some idea of the number of subjects treated in this volume:

Fertilisers—Plant nutrition, 6 pp.; Alkali salts, potash and lime fertilisers, halogens, 44 pp.; Phosphorus, sulphur and compounds, 42 pp.: Nitrogenous fertilisers (nitrogen, oxygen, ozone, hydrogen peroxide, per-salts, oxidation of nitrogen, nitrates, cyanogen derivatives, carbides, acetylene, calcium cyanamide, metallic nitrides, hydrogen, ammonia, ammonium compounds), 128 pp.; Farm manures, mixed fertilisers, plant stimulants, soil sterilisation, 30 pp.; Explosives nitrate powders, chlorate, perchlorate and liquid oxygen explosives, guncotton, nitroglycerine, etc., propellants, aromatic nitro-explosives, detonators, 103 pp.; Pyrotechnics, matches, fire-lighters, fuel briquettes, fire extinguishers, 48 pp.; Fodder, 32 pp.; Foodstuffs—Food preservatives and colourings, starch, flour, bread, sugar, legumes and vegetables, seasonings, milk and dairy products, milk preparations, casein, cheese, edible fats and oils, eggs, flesh, products from blood, ferments and albumin, nutritive salts, 195 pp.; fruits and beverages, organic acids, 52 pp.; tea, coffee, cocoa, tobacco, 30 pp.

The diversity of the subject-matter necessitates the briefest treatment of even the most important processes, and many of the less important ones are dismissed in a few lines with a reference to a patent, usually German. A few examples taken at random will show the scope of the treatment. The description of the various processes for the manufacture of caustic alkali by the electrolyses of alkali chlorides is compressed into three and a third pages. Of the 51 references to literature in this section 15 are to German scientific publications, 1 to this *Journal*, 28 to German patents, 4 to English patents, 2 to American patents and 1 to a Norwegian patent. The manufacture of superphosphate occupies a page, with 10 references to German literature and 1 to English. Three and half pages are devoted to the manufacture and properties of nitroglycerin and the recovery of the waste acids; the description of the actual manufacturing process occupies only a page. There are 33 references to German literature and patents, 3 to French, 2 to American, and 1 to English.

The appearance of this, the third edition, indicates that there is a demand for the book, and it certainly contains a mass of compressed information on a great variety of subjects, many of which are unfamiliar to the ordinary chemist. This applies especially to the section on food stuffs, and the manufacturer of food preparations or his chemist (if he employs one) might obtain a new idea here and there. To British manufacturers engaged in the larger chemical industries, however, the book does not seem to offer much that is not already accessible in English.

J. KNOX

Dr. J. E. Mills has been appointed chief chemist in charge of the research work of the United States Chemical Warfare Service. He has already served many years in the Service as chief co-ordinator at Edgewood Arsenal.

COMPANY NEWS

NOBEL INDUSTRIES, LTD.

According to the report for the year 1923, the gross profit amounts to £1,178,443, an increase of £21,306, whilst the net profit, after meeting the interest on debenture stock requiring £112,977 (against £176,100 for note interest), is £1,065,466, compared with £980,137. During the year the £3,000,000 eight per cent. notes were repaid, and £1,750,000 5½ per cent. debenture stock issued. After providing £30,000 premium on redemption of the notes, and writing off one-thirtieth of the cost of the debenture issue £2977, there remains £1,032,489, to which is added £509,018 brought in, making £1,541,507 available. A dividend of 8 per cent. less tax, has been paid against 7 per cent., less tax, for 1922, and the directors propose to place £100,000 to the special investment reserve (against £50,000), thereby increasing that fund to £500,000, carrying forward the increased balance of £650,130. The cost of note issue has now been wiped out, £186,181 having been taken from the profits of 1922 for the purpose. The cost of debenture issue now stands at £86,333.

CALICO PRINTERS' ASSOCIATION, LTD.

The accounts for the year ended June 30, show a net profit of £540,786, after providing for corporation tax, for maintenance, depreciation, repairs, renewals and upkeep, and for debenture interest. This amount, with £235,432 brought forward, makes available £776,218, of which £155,725 is to be placed to reserve, and £50,000 to the employees' benefit fund. With a dividend of 10 per cent. (less tax on the ordinary shares, £218,614 is left to be carried forward. The net profit for 1922–23 was £800,208 and £237,371 was brought in. The reserve received £150,000, dividend reserve, £150,000, and employees fund, £100,000. The ordinary dividend was 10 per cent., plus a bonus of 2½ per cent., compared with 7½ per cent. paid for 1921–22.

SILICA GEL, LTD.

The registered capital is £315,500 in 300,000 8 per cent. non-cumulative preference shares of £ and 310,000 ordinary shares of 1s. each. The object of the company are to acquire any interests in any invention relating to modern processes and apparatus for effecting the separation of/and or recovering gases, and for processes for the recovery of liquid solutes from non-aqueous solutions and processes for the treatment of liquids, to remove or recover substances therefrom for the manufacture of silica gel and other gels and similar products, or generally any invention which may seem to the company capable of being profitably dealt with; in particular to acquire from the Silica Gel Corporation a right to use and vend all patents and processes, plant machinery and apparatus belonging to that company in connexion with silica gel, and to carry on the business of manufacturers of and dealers in the same and other similar substances, chemists, druggists

drysalters, oil and colourmen, manufacturers of and dealers in chemicals and manures, distillers, dye-makers, gas makers, iron founders, engineers, winners and workers of minerals, producers and workers of metals, and producers and preparers of any other materials, including oil, which may be usefully and conveniently combined with the engineering or manufacturing business of the company, etc.

BRITISH SULPHATE OF COPPER ASSOCIATION, LTD.

The policy of this new Association, which has been registered as a private concern, limited by guarantee, will be the co-ordination of British manufacturers, thereby reducing overhead charges, so as to compete more easily with foreign manufacturers, who by using their depreciated currency, are enabled to sell abroad at "cut" prices. The brands affected by this arrangement are, at present, "Maple," "Three Leaf," "Macclesfield," sometimes called "Crown" and "McKechnie." The control is invested in a management committee, the first members of which are the Mond Nickel Co., Ltd., McKechnie Bros., and J. H. Dennis and Sons.

The registered offices are at 39, Victoria Street, Westminster, S.W. 1, but the headquarters of the Association will eventually be established at Victoria House, Victoria Street, S.W. 1. Mr. W. J. Livesey, sales manager of the Mond Nickel Co., Ltd., is acting as general manager to the Association.

EASTMAN KODAK COMPANY OF NEW JERSEY

A regular dividend of $1\frac{1}{2}$ per cent. on preferred stock, and of 1·25 dollars per share on common stock, and an extra dividend of 75 cents. per share on common stock is payable on October 1.

AMERICAN CYANAMID CO.

The net income for the year ended June 30, amounted to $1,447,026 ($1,878,089 in the preceding year). This figure does not include the net income of the subsidiary companies, amounting, after allowing for taxes, to $108,488. The surplus brought forward was $1,496,352, and the past year's net income provides a total of $2,943,377. The deductions made from this sum are: Sundry charges, less credits for periods prior to July 1, 1923, $69,322; reduction of investment in Amalgamated Phosphate Co., $1,000,000; dividends on preferred stock, $335,754; dividends on common stock, $362,687 (against $65,943). The surplus as at June 30 last is thus reduced to $1,039,268. It is stated that $1,371,576 was expended during the year for additional real estate and for plant extensions, etc., principally at Niagara Falls. The claim of the Government for additional taxes still remains undetermined. Settlements have been made, or arranged for with respect to the principal claims pending against the company growing out of contracts made by the Amalgamated Phosphate Company before its acquisition by this company.

MARKET REPORT

This Market Report is compiled from special information received from the Manufacturers concerned.

Unless otherwise stated the prices quoted below cover fair quantities net and naked at sellers' works.

GENERAL HEAVY CHEMICALS

Acetic Acid, 40% tech. ..	£23 10s. per ton.
Acid, Boric, Commercial—	
Cryst.	£45 per ton.
Powder..	£47 per ton.
Acid Hydrochloric ..	3s. 9d.—6s. per carboy d/d., according to purity, strength and locality.
Acid Nitric 80° Tw. ..	£21 10s.—£27 per ton makers' works, according to district and quality.
Acid Sulphuric	Average National prices f.o.r. makers' works, with slight variations up and down owing to local considerations: 140° Tw., Crude Acid, 65s. per ton. 168° Tw., Arsenical, £5 10s. per ton. 168° Tw., Non arsenical, £6 15s. per ton.
Ammonia Alkali.. ..	£6 15s. per ton, f.o.r. Special terms for contracts.
Bleaching Powder ..	Spot £11 d/d.; Contract £10 d/d. 4 ton lots.
Bisulphite of Lime ..	£7 per ton, packages extra.
Borax, Commercial—	
Crystal..	£25 per ton.
Powder..	£26 per ton. (Packed in 2-cwt. bags, carriage paid any station in Great Britain.)
Calcium Chloride ..	£5 17s. 6d. per ton d/d.
Copper Sulphate	£25 per ton.
Methylated Spirit 64 o.p.—	
Industrial	3s. 1d.—3s. 5d. per gallon, according to quantity.
Mineralised	4s. 2d.—4s. 6d.
Nickel Sulphate	£38 per ton d/d. Normal business.
Nickel Ammon. Sulphate	
Potash Caustic	£30—£33 per ton.
Potass. Bichromate ..	$5\frac{1}{4}$d. per lb.
Potass. Chlorate.. ..	3d.—4d. per lb.
Salammoniac	£32 per ton d/d.
Salt Cake..	£3 10s. per ton d/d.
Soda Caustic, solid ..	Spot lots: delivered £16 17s. 6d. to £19 7s. 6d. per ton, according to strength. 20s. less for contracts.
Soda Crystals	£5 5s.—£5 10s. per ton ex railway depots or ports.
Sod. Acetate 97/98% ..	£24 per ton.
Sod. Bicarbonate ..	£10 10s. per ton, carr. paid.
Sod. Bichromate.. ..	$4\frac{1}{2}$d. per lb.
Sod. Bisulphite Powder 60/62%..	£18—£19 per ton, according to quantity, f.o.b., 1-cwt. iron drums included.
Sod. Chlorate	3d. per lb.
Sod. Nitrate refd. 96% ..	£13 5s.—£13 10s. per ton ex Liverpool. Nominal.
Sod. Sulphide conc. 60/65	About £14 10s. per ton d/d.
Sod. Sulphide cryst. ..	£9 per ton d/d.
Sod Sulphite, Pea Cryst.	£15 per ton f.o.r. London, 1-cwt kegs included.

RUBBER CHEMICALS

Antimony sulphide—	
Golden	$5\frac{3}{4}$d.—1s. 4d. per lb., according to quality.

Antimony sulphide—	
Crimson	.. 1s. 3d.—1s. 6d. per lb., according to quality.
Arsenic, Sulphide, Yellow	1s. 11d. per lb.
Barytes	.. £3 10s. to £6 15s. per ton, according to quality.
Cadmium Sulphide	.. 3s. 9d.—4s. per lb., according to quantity.
Carbon Bisulphide	.. £30—£33 per ton, according to quantity. Again dearer.
Carbon Black ..	.. 7d.—7½d. per lb. ex wharf. Dearer.
Carbon Tetrachloride	.. £60—£65 per ton, according to quantity, drums extra. Again dearer.
Chromium Oxide, green ..	1s. 3d. per lb.
Indiarubber Substitutes White and Dark ..	5d.—9½d. per lb. Demand very brisk. Prices likely to remain steady owing to firmness of rapeseed oils.
Lamp Black ..	.. £48 per ton, barrels free. Advanced.
Lead Hyposulphite	.. 7½d. per lb.
Lithopone, 30% ..	.. £22 10s. per ton.
Mineral Rubber "Rubpron"	.. £16 5s. per ton f.o.r. London.
Sulphur	.. £10—£12 per ton, according to quality.
Sulphur Precip. B.P.	.. £56—£57 per ton, according to quantity.
Sulphur Chloride	.. 4d. per lb., carboys extra. Dearer.
Thiocarbanilide ..	.. 2s. 6d. per lb.
Vermilion, pale or deep ..	5s. 1d. per lb. dearer.
Zinc Sulphide ..	.. 7½d.—1s. 8d. per lb., according to quality.

WOOD DISTILLATION PRODUCTS

"Summer conditions" prevail in this as in most industries.

Acetate of Lime—	
Brown	.. £12—£12 5s. per ton d/d. Market easier.
Grey	.. £17—£18 per ton. Market easier.
Liquor	.. 9d. per gall. 32° Tw.
Charcoal	.. £7 10s.—£9 per ton, according to grade and locality. Demand fairly good.
Iron Liquor ..	.. 1s. 7d. per gall. 32° Tw. 1s. 2d. ,, ,, 24° Tw.
Red Liquor ..	.. 10d.—1s. per gall. 14/15° Tw.
Wood Creosote ..	.. 2s. 7d. per gall. Unrefined.
Wood Naphtha—	
Miscible ..	.. 4s. 10d.—5s. per gall. 60% O.P. Market dull.
Solvent	.. 5s. 6d. per gall. 40% O.P. Fairly good demand.
Wood Tar ..	.. £4 per ton. Cheaper.
Brown Sugar of Lead ..	£44 per ton. Cheaper.

TAR PRODUCTS

Acid Carbolic—	
Crystals ..	.. 6½d. per lb. Quiet.
Crude 60's ..	.. 1s. 9d.—1s. 11d. per gall, according to district. Still quiet.
Acid Cresylic, 97/99	.. 2s.—2s. 1d. per gall. Demand fair.
Pale 95% ..	.. 1s. 9d.—2s. per gall.
Dark	.. 1s. 9d.—2s. per gall. Quiet.
Anthracene Paste 40% .	4d. per unit per cwt. Nominal price. No business.
Anthracene Oil—	
Strained ..	.. 7½d.—9d. per gall. Quiet.
Unstrained ..	.. 6½d.—7½d. per gall.
Benzole—	
Crude 65's ..	.. 7½d.—9d. per gall. ex works in tank wagons.
Benzole—	
Standard Motor	.. 1s. 1½d.—1s. 3d. per gall. ex works in tank wagons.
Pure	.. 1s. 5½d.—1s. 7d. per gall. ex works in tank wagons.
Toluole—90% ..	.. 1s. 5d.—1s. 5½d. per gall. Small demand.
Pure ..	.. 1s. 8d.—2s. per gall. Small demand.
Xylol coml. ..	.. 2s. 3d. per gall.
Pure ..	.. 3s. 3d. per gall.
Creosote—	
Cresylic 20/24%	..8 ½d. per gall. Not much business.
Middle Oil .. Heavy Oil .. Standard Specification	5d.—6½d. per gall., according to quality and district. Small export inquiry. Market quiet but fairly steady.
Naphtha—	
Solvent 90/160	.. 11d.—1s. 5d. per gall., according to district. Fair demand.
Solvent 90/190	.. 11d.—1s. 4d. per gall. Fair demand.
Naphthalene Crude—	
Market dull. Not much export inquiry. Cheaper in Yorkshire than Lancashire.	
Drained Creosote Salts £4—£6. Quiet.	
Whizzed or hot pressed £7—£9 per ton.	
Naphthalene—	
Crystals and Flaked	.. £13—£16 per ton in Yorkshire and London respectively.
Pitch, medium soft	.. 55s.—60s. per ton f.a.s. for next season. Frequent inquiries.
Pyridine—90/160	.. 19s. per gall. Again dearer. Market firm.
Heavy ..	.. 12s.—12s. 6d. Little business.

INTERMEDIATES AND DYES

Business in dyestuffs has improved and enquiries are now much better. Prices remain firm.

In the following list of Intermediates delivered prices include packages except where otherwise stated.

Acetic Anhydride 95% ..	1s. 7d. per lb.
Acid H.	.. 4s. per lb. 100% basis d/d.
Acid Naphthionic	.. 2s. 4d. per lb. 100% basis d/d.
Acid Neville and Winther	5s. 8d. per lb. 100% basis d/d.
Acid Salicylic, tech.	.. 1s. 1d. per lb. Improved demand.
Acid Sulphanilic	.. 9½d. per lb. 100% basis d/d.
AluminiumChloride,anhyd.	1s. per lb. d/d.
Aniline Oil ..	.. 7¾d.—8½d. per lb. naked at works.
Aniline Salts ..	.. 7¾d.—9d. per lb. naked at works.
Antimony Pentachloride	1s. per lb. d/d.
Benzidine Base ..	.. 4s. 6d. per lb. 100% basis d/d.
Benzyl Chloride 95%	.. 1s. 1d. per lb.
p-Chlorphenol ..	.. 4s. 3d. per lb. d/d.
p-Chloraniline ..	.. 3s. per lb. 100% basis.
o-Cresol 19/31° C.	.. 4½d. per lb. Demand steady.
m-Cresol 98/100%	.. 2s. 1d.—2s. 3d. per lb. Demand moderate.
p-Cresol 32/34° C.	.. 2s. 1d.—2s. 3d. per lb. Demand moderate.
Dichloraniline ..	.. 3s. per lb.
Dichloraniline S. Acid	.. 2s. 6d. per lb. 100% basis.
p-Dichlorbenzol ..	.. £85 per ton.
Diethylaniline ..	.. 4s. 6d. per lb. d/d., packages extra, returnable.
Dimethylaniline ..	.. 2s. 3d. per lb. d/d. Drums extra.
Dinitrobenzene ..	.. 9d. per lb. naked at works.
Dinitrochlorbenzol	.. £84 10s. per ton d/d.
Dinitrotoluene—48/50° C.	8d.—9d. per lb. naked at works.
66/68° C.	1s. 2d. per lb. naked at works.
Diphenylamine ..	.. 2s. 10d. per lb. d/d.
Monochlorbenzol ..	.. £63 per ton.
βNaphthol ..	.. 1s. 1d. per lb. d/d.
αNaphthylamine	.. 1s. 4d. per lb. d/d.

βNaphthylamine	4s. per lb. d/d.
m-Nitraniline	4s. 9d. per lb. d/d.
p-Nitraniline	2s. 3½d. per lb. d/d.
Nitrobenzene	5¼d.—5½d. per lb. naked at works.
o-Nitrochlorbenzol	2s. per lb. 100% basis d/d.
Nitronaphthalene	10½d. per lb. d/d.
p-Nitrophenol	1s. 9d. per lb. 100% basis d/d.
p-Nitro-*o*-amido-phenol	4s. 6d. per lb. 100% basis.
m-Phenylene Diamine	4s. per lb. d/d.
p-Phenylene Diamine	10s. 3d. per lb. 100% basis d/d.
R. Salt	2s. 6d. per lb. 100% basis d/d.
Sodium Naphthionate	2s. 3d. per lb. 100% basis d/d.
o-Toluidine	8½d. per lb.
p-Toluidine	3s. 3d. per lb. naked at works.
m-Toluylene Diamine	4s. 3d. per lb. d/d.

PHARMACEUTICAL AND PHOTOGRAPHIC CHEMICALS

Acid, Acetic 80% B.P.	£47 per ton.
Acid, Acetyl Salicylic	3s. 1d.—3s. 3d. per lb., according to quantity.
Acid, Benzoic B.P.	3s. per lb.
Acid Boric B.P.	Cryst. £51 per ton, Powder £55 per ton. Carriage paid any station in Great Britain.
Acid, Camphoric	19s.—21s. per lb.
Acid, Citric	1s. 4½d.—1s. 5d. per lb., less 5% for ton lots. Market very weak.
Acid, Gallic	3s. per lb. for pure crystal.
Acid, Pyrogallic, Cryst.	6s. 9d. per lb. Resublimed quality 8s. per lb. Market firm, increasing demand.
Acid, Salicylic	1s. 6d.—1s. 9d. per lb., according to quantity. Demand rather easier.
Acid, Tannic B.P.	3s. per lb. Market quiet.
Acid, Tartaric	1s. 1¼d. per lb less 5%.
Amidol	9s. per lb. d/d.
Acetanilide	2s. 1d.—2s. 3d. per lb. for quantity. Demand slow.
Amidopyrin	13s. 3d. per lb. Neglected. Stocks low.
Ammon. Benzoate	3s. 3d.—3s. 6d. per lb. according to quantity.
Ammon. Carbonate B.P.	£37 per ton.
Atropine Sulphate	12s. 6d. per oz. for English make.
Barbitone	15s.—15s. 6d. per lb. Quiet market.
Benzonaphthol	5s. 3d. per lb. Small inquiry.
Bismuth Salts	Prices reduced by about 1s. 3d.—2s. 3d. per lb. on account of the fall in the price of the metal.
Bismuth Carbonate	10s. 6d.—12s. 6d. per lb.
,, Citrate	10s. 3d.—12s. 3d. ,,
,, Salicylate	9s.—11s. ,,
,, Subnitrate	8s. 8d.—10s. 8d. ,,
Borax B.P.	Crystal £29, Powder £30 per ton. Carriage paid any station in Great Britain.
Bromides	Market firm, and Continental prices fully maintained with upward tendency.
Ammonium	1s. 4d.—1s. 7d. per lb.
Potassium	1s. 2d.—1s. 5d. per lb.
Sodium	1s. 3d.—1s. 6d. per lb.
Calcium Lactate	1s. 7d.—1s. 9d., according to quantity. Fair demand and steady market.
Chloral Hydrate	4s.—4s. 3d. per lb. Very firm and scarce.
Chloroform	2s. per lb. for cwt. lots. Very steady.
Creosote Carbonate	6s. 6d. per lb. Little demand.
Formaldehyde	£52 per ton, *ex* works. English make in casks.
Glycerophosphates—	Fair business passing.
Calcium, soluble and citrate free	7s. per lb.
Iron	8s. 9d. per lb.
Magnesium	9s. per lb.
Potassium, 50%	3s. 6d. per lb.
Sodium, 50%	2s. 6d. ,,
Guaiacol Carbonate	10s. 6d.—11s. 3d. per lb.
Hexamine	3s. 6d. per lb. for English make—market steady.
Homatropine Hydrobromide	30s. per oz.
Hydrastine hydrochlor	English make offered, 120s. per oz.
Hypophosphites—	
Calcium	3s. 6d. per lb., for 28-lb. lots.
Potassium	4s. 1d. per lb.
Sodium	4s. ,,
Iron. Ammon. Citrate B.P.	2s. 1d.—2s. 5d. per lb.
Magnesium Carbonate—	
Light Commercial	£36 per ton net.
Magnesium Oxide—	
Light Commercial	£75 per ton, less 2½%.
Heavy Commercial	£25 per ton, less 2½%. Price reduced.
Heavy Pure	2s.—2s. 3d. per lb., according to quantity. Steady market.
Menthol—	
A.B.R. recryst. B.P.	57s. 6d. per lb.
Synthetic	26s.—35s. per lb., according to quantity. English make. Good demand. Steady market.
Mercurials	Market very quiet.
Red oxide	5s. 3d.—5s. 4d. per lb.
Corrosive sublimate	3s. 6d.—3s. 7d. ,,
White precip.	4s. 7d.—4s. 8d. ,,
Calomel	3s. 11d.—4s. ,,
Methyl Salicylate	1s. 10d.—2s. 1d. per lb. Keen competition.
Methyl Sulphonal	26s. per lb.
Metol	11s. per lb. British make.
Paraformaldehyde	2s. 10½d.—3s. per lb. Not very active.
Paraldehyde	1s. 5d.—1s. 6d. per lb. in free bottles and cases.
Phenacetin	6s. per lb. Price and demand steady.
Phenazone	7s. 6d. per lb. A shade firmer. Forward prices higher.
Phenolphthalein	6s. 6d. per lb. Ample supplies.
Potass. Bitartrate—99/100% (Cream of Tartar)	88s. per cwt., less 2½% for ton lots. Firm market. Prices have upward tendency.
Potass. Citrate	1s. 10d.—2s. 2d. per lb.
Potass. Iodide	16s. 8d.—17s. 5d. per lb., according to quantity. Good steady demand.
Potass. Metabisulphite	7½d. per lb., 1-cwt. kegs included.
Potass. Permanganate	7¼d. per lb.
Quinine Sulphate	2s. 3d.—2s. 4d. per oz., in 100 oz. tins. Steady market.
Resorcin	5s. 2d. per lb.
Saccharin	63s. per lb., in 50-lb. lots.
Salol	3s. 6d. per lb.
Silver Proteinate	9s. 6d. per lb.
Sod. Benzoate, B.P.	2s. 6d. per lb. Ample supplies. B.P. quality available.
Sod. Citrate, B.P.C., 1923	1s. 11d.—2s. 2d. per lb., according to quantity.
Sod. Hyposulphite—Photographic	£13—£15 per ton, according to quantity, d/d. consignee's station in 1-cwt. kegs.

Sod. Metabisulphite cryst.	37s. 6d.—60s. per cwt. nett cash, according to quantity.
Sod. Nitroprusside ..	16s. per lb.
Sod. Potass. Tartrate (Rochelle Salt) ..	75s.—82s. 6d. per cwt., according to quantity. Quiet market.
Sod. Salicylate	Market rather easier. Powder 2s. 1d.–2s. 3d. per lb. Crystal at 2s. 3d.–2s. 5d. per lb. Flake 2s. 9d. per lb.
Sod. Sulphide—	
Pure recryst.	10d.—1s. 2d. per lb.
Sod. Sulphite, anhydrous	£27 10s.–£28 10s. per ton, according to quantity, 1-cwt. kegs included. In large casks £1 per ton less.
Sulphonal..	15s. 6d. per lb. Easier.
Thymol	20s. per lb. nominal. Very scarce indeed.

PERFUMERY CHEMICALS

Acetophenone	12s. 6d. per lb.
Aubepine	15s. 3d. ,,
Amyl Acetate	2s. 6d. ,,
Amyl Butyrate	6s. 9d. ,,
Amyl Salicylate	3s. ,,
Anethol (M.P. 21/22° C.)	4s. 6d. ,,
Benzyl Acetate from Chlorine-free Benzyl Alcohol	2s. 9d. ,,
Benzyl Alcohol free from Chlorine	2s. 9d. ,,
Benzaldehyde free from Chlorine	3s. 6d. ,,
Benzyl Benzoate.. ..	3s. 6d. ,,
Cinnamic Aldehyde—	
Natural	16s. ,,
Coumarin	19s. 6d. ,,
Citronellol	17s. ,,
Citral	8s. 6d. ,,
Ethyl Cinnamate ..	12s. 6d. ,,
Ethyl Phthalate	3s. 3d. ,,
Eugenol	10s. 6d. ,,
Geraniol (Palmarosa) ..	35s. ,,
Geraniol	11s.—18s. 6d. per lb.
Heliotropine	7s. 3d. ,,
Iso Eugenol	15s. 9d. ,,
Linalol ex Bois de Rose..	26s. ,,
Linalyl Acetate	26s. ,,
Methyl Anthranilate ..	9s. 6d. ,,
Methyl Benzoate.. ..	5s. ,,
Musk Ambrette	45s. ,,
Musk Xylol	14s. ,,
Nerolin	4s. 9d. ,,
Phenyl Ethyl Acetate ..	15s. ,,
Phenyl Ethyl Alcohol ..	16s. ,,
Rhodinol	60s. ,,
Safrol	1s. 10d. ,,
Terpineol	2s. 4d. ,,
Vanillin	26s. per lb.

ESSENTIAL OILS

Almond Oil, Foreign S.P.A.	15s. 6d. per lb.
Anise Oil	2s. 6d. per lb.
Bergamot Oil	17s. 6d. per lb.
Bourbon Geranium Oil ..	36s. 0d. per lb.
Camphor Oil	65s. per cwt.
Cananga Oil Java ..	10s. 6d. per lb.
Cinnamon Oil, Leaf ..	6½d. per oz.
Cassia Oil, 80/85% ..	10s. per lb.
Citronella Oil—	
Java 85/90%	5s. 8d. per lb.
Ceylon	3s. 7d. per lb.
Clove Oil	7s. 6d. per lb.
Eucalyptus Oil, 70/75%..	2s. 3d. per lb.
Lavender Oil—	
French 38/40% Esters	27s. 6d. per lb.
Lemon Oil	3s. per lb.
Lemongrass Oil	3d. per oz.
Orange Oil, Sweet ..	11s. per lb.
Otto of Rose Oil—	
Bulgarian	37s. 6d. per oz. Production below average.
Anatolian	18s. per oz.
Palma Rosa Oil	17s. per lb.
Peppermint Oil—	
Wayne County ..	27s. per lb. Market very active and prices rising.
Japanese	17s. 6d. per lb.
Petitgrain Oil	9s. 3d. per lb.
Sandal Wood Oil—	
Mysore	26s. 7d. per lb.
Australian	21s. per lb.

PATENT LIST

The dates given in this list are, in the case of Applications for Patents those of applications, and in the case of Complete Specifications accepted those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition before Nov. 3rd; they are on sale at 1s. each at the Patent Office, Sale Branch, Quality Court, Chancery Lane, London, W.C. 2, on Sept 18th.

I.—Applications

Bendixen. Apparatus for extraction, solution, and mixing. 20,295. Aug. 27.

Chem. Fabr. vorm. Sandoz. Preparation of an adsorption compound. 20,477. Aug. 29. (Switz., 20.9.23.)

I.—Complete Specifications Accepted

5549 (1923). Baker-Perkins, Baker, Prescott, and Gilderdale. Centrifugal separators. (220,671.)

13,626 (1923). Lenz and Jupp. Apparatus for separating liquids of different specific gravities. (220,713.)

13,688 (1923). Eldred. Recovery of values from mixtures. (220,716.)

29,638 (1923). Delpech. Dehydration of air containing volatile substances. (220,858.)

30,401 (1923). Tugwood (Jeffrey Manuf. Co.). Crushing-machines. (220,862.)

32,197 (1923). British Thomson-Houston Co., Ltd. Separating vapour, or vapour and liquid, from a non-condensible gas. (209,081.)

7811 (1924). Somerville and Williams. Application of absorbent materials. (220,899.)

13,112 (1924). Rheinische Maschinenfabrik. Crushing-mills. (216,886.)

II.—Applications

Allan, Moore, and Burmah Oil Co. Wax sweating and crystallising apparatus. 20,132. Aug. 29.

Brooke. Retort settings in gas manufacture. 20,138. Aug. 26.

Curties. Fuel for firing bricks etc. 20,128. Aug. 26.

Dewar. Carbonisation of coal etc. 20,478. Aug. 29.

Dewar. Production of smokeless fuel etc. from coal. 20,479. Aug. 29.

Fuchs. Heating arrangement for petroleum distillation etc. 20,376. Aug. 28. (Austria, 28.8.23.)

Leadbeater. 20,215. *See* XIII.

Seidenschnur. 20,516. *See* III.

Stern. Removal of water from fine coal. 20,453. Aug. 29.

Terry. Fuels for internal-combustion engines. 20,400. Aug. 28.

II.—Complete Specifications Accepted

4924 and 30,128 (1923). Auld, Dunstan, and Herring. Treatment of liquid hydrocarbons. (220,664.)

8107 (1923). Nielsen and Laing. Gas manufacture. (220,676.)

10,685 (1923). Vickers, Ltd., and Lucas. Retort furnaces. (220,684.)
13,259 (1923). Marconnet. Gas-generators. (197,948.)
13,963 (1923). Davidson and Lewis. Cracking of hydrocarbon oils and the treatment of solid carbonaceous substances. (220,732.)

GENERAL NOTES

Official Trade Intelligence

The Department of Overseas Trade (Development and Intelligence, 35, Old Queen Street, London. S.W. 1), has received the following enquiries for British goods. British firms may obtain further information by applying to the Department and quoting the specific reference number:—*British India*: Steel (Director-General, India Store Department, Branch

No. 10, Belvedere Road, Lambeth, S.E. 1); *Belgium*: Cast iron and steel (A.X./1286); *Canada*: Paper, Rubber goods (260); Leather (B.X./1198); *Denmark*: Copper, mercury, and soda products (265); *Dominican Republic*: Oil, paints, chemicals (278); *South Africa*: Cast iron (A.X./1279); Oil (B.X./1187); *United States*: Leather (B.X./1203).

Dyestuffs (Import Regulation) Act, 1920

The following statement relating to applications for licences under the Dyestuffs (Import Regulation) Act, 1920, made during August has been furnished to the Board of Trade by the Dyestuffs Advisory Licensing Committee: The total number of applications received during the month was 421, of which 330 were from merchants or importers. To these should be added 12 cases outstanding on August 1, making a total for the month of 433. These were dealt with as follows: Granted, 327 (of which 304 were dealt with within seven days of receipt). Referred to British makers of similar products—69 (of which 54 were dealt with within 7 days of receipt). Referred to Reparation Supplies available, 25 (all dealt with within two days of receipt). Outstanding on August 31, 1924, 12. Of the total of 433 applications received, 383 or 88 per cent. were dealt with within seven days of receipt.

Exports of Chemicals from the United States

Exports of chemicals and allied products from the United States during the first six months of 1924 were valued at $67,328,598, a decline of 10 per cent. compared with the export during the same period of 1923, when the value was $74,836,422. The decline was due to smaller exports of industrial chemicals, coal-tar products, fertilisers, explosives, gums, resins, paints and varnishes. Exports of fine chemicals, though forming only a small proportion of the total, showed a gain.

Canadian Chemical Production in 1923

The High Commissioner for Canada in London has received from the Dominion Bureau of Statistics at Ottawa, a preliminary estimate made by Mr. S. J. Cook, Chief of the Mining, Metallurgical and Chemical Branch, showing that the production of chemicals and allied products in Canadian factories last year reached a total value of more than $106,500,000.

Exports of Canadian products in this class were valued at 15·7 million dollars, and imports amounted to 26·1 million dollars in the same period. Over 124 million dollars of capital was invested in concerns operating 466 plants and employment was furnished to about 14,600 employees. Salaries and wages paid totalled 17·8 million dollars, and the cost of materials used was about 52·9 million dollars. The value added by manufacturing or the difference betewen the selling value of the products made and the cost of raw materials used in their manufacture was 53·5 million dollars. Increases were noted in the amount of capital employed, the number of employees, payments of salaries and wages, cost of materials and value of products, as well as in the value of imports and exports.

Nearly 82 per cent. of the 1923 chemical exports went to the United States, United Kingdom and Mxeico in the order named, and nearly 13 per cent. was shipped to Newfoundland, Japan, British West Indies, Australia and New Zealand. On the other side, more than 98 per cent. of Canada's import business in chemical products was from seven countries with the United States leading and the United Kingdom next, followed by Germany, France, the Netherlands, Belgium and Switzerland. The remaining 2 per cent. of Canada's chemical import trade was drawn from more than a score of different countries.

Trade Information

The Electric Furnace Company, Ltd.—Arrangements have been made by which Automatic and Electric Furnaces, Ltd., and the Electric Furnace Co., Ltd., will jointly design Wild-Barfield internally-heated electric furnaces having an input greater than 25 k.w., which in future will be supplied by the latter company. Arrangements have also been made with George J. Hagan Co., of Pittsburg, U.S.A., who have constructed a large number of electric resistance furnaces up to 350 k.w. capacity, for the use of their drawings and information, so that the best British and American practice will be incorporated in the designs.

Foreign Company News

The report of the Cie Belge de l'Union Minière du Haut Katanga for 1923 records a total output of copper amounting to 57,886 m.t. (43,362 tons in 1922, and 30,464 t. in 1921), the production in June, 1924, being estimated at 7000 t., since when the output has increased. In the area held by the company, investigations have shown the existence of copper ores estimated at 72,660,000 t., containing 6·20 per cent. of copper. Cobalt is also abundant, and three electrical furnaces have been installed at Panda to produce a copper-cobalt-iron alloy, which is treated in Belgium by the Société Générale Metallurgique de Hoboken. Work at the radio-active deposit at Chinkolobwe has resulted in shipments of large quantities of ore to the Oolen Works in Belgium, which can now furnish two-thirds of the world's consumption of radium. The company finds employment in Africa for 916 Europeans and 10,059 natives.

The Société Chimique des Usines du Rhône is producing 500 kg. of acetate silk daily in its Roussillon factory, and the plant is to be extended. Two new factories are to be built, one for the preparation of the artificial fibre and the other for spinning the Rhodiaseta artificial silk. The new factories are planned to produce four tons a day, although the production at first will be only one ton.

The Société des Matières Colorantes et Produits Chimiques de St. Denis (Etablissements Poirrier et Dalsace), has decided to increase its capital from 24,000,000 to 30,000,000 francs.

VOL. 43 NEW SERIES | LONDON, SEPTEMBER 19, 1924 | NO. 38

EDITORIAL

THERE are many indications that in the political world, criticism from those who have no responsibility is far simpler than progress on the part of those who have the detailed knowledge of the obstacles to progress, and the responsibility of carrying proposals to a successful issue. Those who stand on the top of a cliff and watch the ships struggling in the storm see how easy it is to make for smoother water. Those whose business it is to write books or plays can with case solve the problems of peace and war, restore our trade to its former prosperity, and persuade the trade unionist to do the maximum of work in the shortest possible time, and secure, in spite of foreign competition, such a remuneration as will enable him to cultivate the muses in his abundant spare time. Mr. Bernard Shaw can solve our marriage and property problems, and discover instant remedies for all the ills which confront modern civilisation. Mr Tom Shaw, our Minister of Labour, finds some of these problems not quite so easy. Prof. Soddy, by his new system of economics, can make us all happier and richer: Mr. Sidney Webb, presiding over the Board of Trade, is thankful for an improvement so slow as almost to require a microscope. The Communists see how easy it is to promote an era of universal peace; meanwhile, the generals in Morocco, in China, in Georgia, and in some countries nearer to our own country, sharpen their swords and prepare reserves of high explosives. It is not only in the political world that this is true; it is true, also, in the chemical world and in almost every other aspect of human organisation. If a few individuals of rather more than average intelligence and industry are striving to do their best with an awkward situation, it must be remembered that they are probably acquainted not only with the difficulties obvious to the critic, but with many other difficulties unknown to him, some of which perhaps—for reasons of expediency—they do not even desire to mention publicly. The successful accomplishment of a task is not, therefore, to be taken as a mere matter of course; it looks easy, perhaps, but everything looks easy until you attempt it. We have just read in the Transactions of the Institution of Chemical Engineers the brief account of the formation of that body, and we have somewhat hastily perused the scientific papers which form the bulk of that volume. We are struck by the fact that so considerable an achievement has been accomplished in so brief a period of time. We are well aware of the existence of critics of the Institution; that proves nothing. The papers on "Industrial Oxygen," by Mr. Finlayson; on "Absorption Towers," by Messrs. Donald and Tyson; on "Flow in Filter Presses," by Messrs. Donald and Hunneman; and on "Corrosion," by Mr. Donald, together with Mr. Alliott's excellent bibliography, prove that the Institution is making important additions to our knowledge, printing them clearly in good type and a convenient form, and justifying its existence and prosperity. Let us think for a moment of the difficulties which are certain to have existed though our knowledge of them is so meagre, and offer our sincere congratulations to the Institution on its flourishing state and the excellent standard it has set.

* * *

The oyster—we are speaking of the race not of the individual—has a long and a glorious history. He has been honoured by many of the Greek and Latin poets; Juvenal mentions the connoisseur who could tell immediately whether the morsel, it could hardly be described as a mouthful, came from the Lucrine rocks or from Whitstable. Writers of poetry, verse and prose, in all ages and in most languages, have paid well-deserved compliments to this delicacy. To us the British oysters are the best, but we recollect

superb specimens culled from American, French, Dutch and Portuguese waters and the native men and women of those countries may even prefer their own natives to their settlers. These children of the rocks and grey sea to use a phrase of Alcæus, have a due place in the economy of Nature. There are, we know, some misguided but useful people who value, not the ostrean virtue; to sit next to one of these at a public banquet, which includes the inspiring delicacy, is a privilege that may be due to cunning or to happy chance. On such an occasion, secure of fate the epicure may say, "Fate cannot harm me, I shall dine to-day." From his grateful soul he pours forth a sincere thanksgiving, commencing with the melodious phrase, "Bountiful Jehovah!" Careless students, learned professors, wily doctors and convalescent patients have blessed the oyster. Our Government chemists—glory be to them—have given a rational explanation of its tonic qualities. The oyster collects, assiduously and laboriously, arsenic from the sea-water and the solid particles which carpet the bottom of the ocean, the mattress, as it were, of the oyster-bed. The oyster may contain from one to three parts per million of arsenic: three dozen oysters may contain as much as a medicinal dose; the oyster frequently contains so much arsenic as to exceed that narrow limit authorised and hall-marked as safe. The present Minister of Health may earn undying fame by adopting as a new standard the limit adopted by that sagacious epicure, the oyster. This short note contains all that is worth remembering in a Report on Oysters just published by the Ministry of Agriculture and Fisheries; those who love evidence and statistics should buy the Report; those who love oysters should store in their cellar a barrel of Colchester ones and another barrel of Whitstable, and in their minds the contents of this editorial summary.

* * *

Prof. J. C. Drummond treats of the cod and the oil extracted from the cod-liver in a manner more instructive and more dignified. Problems of health and nutrition are not the occasion for indecent mirth or airy persiflage. Prof. Drummond and his co-workers have made a study of vitamins in a thoroughly scientific spirit. They have shown us the very constituent of cod-liver oil which includes the two vitamins which have brought cod-liver oil into such universal use: soon we may learn more of the constitution of that alcohol which now seems so essential. It is singular that the vitamins are so indestructible by the ordinary processes of digestion, and we wonder whether cormorants and other fish-eating birds are able to store up for their own gratification vitamins A and D derived from diatoms in the indirect manner described in Prof. Drummond's article. We do not recollect any account of the fate of the vitamins in the human body. What happens to them there? Are they stored up in our livers, or do they undergo some sort of oxidation of the same sort as the oxidation of starch in our bodies? Are the vitamins substances or are they merely phases in the life-history of a substance, as we are told enzymes are?

COD LIVER OIL *

By PROF. J. C. DRUMMOND

Historical

The general use of cod liver oil in the treatment of conditions of malnutrition and the associated diseases is of comparatively recent date. There is evidence that both the livers themselves and the oil derived from them were used as household remedies for centuries along many coast lines, particularly those of Scandinavia and Japan. From Norway it appears to have been introduced into Germany, probably by the Hanseatic merchants trading with Bergen, and under the name Bergenthran was used to a limited extent in the seventeenth and eighteenth centuries.

It is uncertain, however, whether its use spread from Germany to England, or whether in our country it arose directly from the reputation that liver oils had established on the coast of North Scotland as a cure for rickets (Barton, "De Rachitide," Diss., Edinburgh), or from the fact that considerable quantities of "train oil" were imported every year along the well-known trade route between Newfoundland and the villages and towns of the Dorsetshire coast. Thomas Hardy in "A Changed Man" refers to the importation of "trayne oyle" into Wessex from Newfoundland as far back as 1540. This oil would appear to have been sometimes cod liver oil, but more frequently whale oil. However, about 1766, we find a physician, Dr. Kay, prescribing cod liver oil at the Manchester Infirmary on a scale sufficient to consume 50—60 gallons a year (Percival, Medical Essays, Warrington, 1789. Treatise on Oleum Jecoris Aselli or Cod Liver Oil as a Therapeutic Agent in certain forms of Gout, Rheumatism and Scrofula; John Hughes Bennett, London, 1841). Writing of the use of the oil at Manchester Infirmary, Bardsley (*Med. Rep.*, London, 1807) remarks. "This medicine has preserved its reputation unimpaired for the period of 30 years."

Apparently during this period the Infirmary was visited by a German physician, Dr. Schenck of Siegen, who returned to Germany deeply impressed with what he had seen of the therapeutic use of cod liver oil. Schenck, in a memoir in *Hufeland's Journal*, published in 1822, strongly emphasised the value of the oil, and largely on his urging it was established as a remedy in the pharmacopœia of Prussia, Hanover, Saxony, Sleswig and Holstein.

This seems to have led to a somewhat widespread use of the oil in Germany and to a vigorous expansion of the trade in Norwegian oil from Bergen. Prof. Naegele of Dusseldorf informed Dr. Bennett in 1840 that the peasants seldom applied to him until after they had tried the effect of taking cod liver oil at home. About 1830 the use of the oil spread to France and soon became general over Western Europe.

The almost specific action of cod liver oil in the treatment of rickets and diseases of malnutrition

* Lecture delivered before Section I (Physiology), British Association for Advancement of Science, Toronto meeting, August, 1924.

was appreciated quite early, and theories to account for its beneficial effect were soon forthcoming.

Old Theories concerning Therapeutic Value

Willmot ("Glycerin and Cod Liver Oil. Their History, Introduction, Therapeutic Value and Claims upon Professional and Public Attention," London, 1860) gives an amusing account of some of these earlier ideas on this subject. Some of them were most fantastic, as was one advanced by a Fellow of the Royal Society, named Smee, in which electric phenomena were held to play a part, whereas of the more rational ones was that put forward by the great chemist Liebig, who remarked: "In the animal body we recognise as the ultimate cause of all force only one cause, the chemical action which the elements of the food and the oxygen of the air mutually exercise on each other. Cod liver oil furnishes carbonaceous fuel for respiration, and thus protects the tissues from the action of atmospheric oxygen."

It is not surprising to find that others sought for the explanation of the peculiar action of cod liver oil in the chemical differences which can be detected between this and other oils. Of these, the fact that cod liver oil usually contained traces of iodine was soon seized upon and advanced as an explanation of its therapeutic activity about 1830 by a Dr. Kopp (*cf.* Hoppe de l'Orme, *Hufeland's Journal*, 82, 115). That iodine was present was actually keenly contested for some time until finally confirmed by the experiments of Gmelin (*Ann. der Pharm.*, 31, 323), but the opponents of the iodine theory, as we may call it, then argued that so small a trace of iodine as is usually found, *i.e.*, 1 part in 40,000, could scarcely be responsible for the beneficial effects observed (*cf.* Falker, *Heidelbg. Med. Ann.*, 1840, 6). To this supporters of the theory replied that not only did the iodine content run parallel with the potency of the oil, but that the iodine was probably present in some peculiar state of combination that made it physiologically more potent than when given in other forms (Bennett, J. H., "Treatise on the Oleum Jecoris Aselli," London, 1841). Later, with the advance of chemical science came the knowledge that the fatty acids of cod liver oil are more highly unsaturated than those occurring in most other oils, and from the fact that highly unsaturated acids are readily oxidised in the laboratory grew the belief that the mal-nourished organism might assimilate and oxidise such acids when it was too weak to make use of those ordinarily occurring in other oils and fats (Williams, *B.M.J.*, 1912, **2**, 700; *Pharm. J.*, 1913, **89**, 806).

Vitamin Theory

Such was the position when, following Hopkin's discovery of the vitamins in 1912 it was suggested by Funk (*Die Vitamine*, *Wiesbaden*, 1914) that the curative value of cod liver oil is due to the presence of these substances. At the same time it was shown by Osborne and Mendel (*J. Biol. Chem.*, 1914, **17**, 401), that cod liver oil actually contains a growth-promoting substance absent from many other oils the vegetable oils in particular. Even this fact could be reconciled with either of the current theories, but quite a new aspect of the problem was opened up when McCollum and Davis in 1914 (*J. Biol. Chem.*, **19**, 245) reported that the growth promoting principle withstands saponification of the oil in which it is present. Curiously, this important discovery attracted little attention at the time, and was not confirmed until six years later by Steenbock and Boutwell (*J. Biol. Chem.*, 1920 **42**, 121), and by Drummond and Coward (*Lancet*, 1921, ii, 698), who found that the active substance passed into the unsaponifiable fraction. Soon afterwards Zucker, Pappenheimer and Barnett showed that the antirachitic factor also passes into this fraction (*Proc. Soc. Exper. Biol. and Med.*, 1922, **19**, 167). This fraction prepared from cod liver oil appears to possess the whole of the physiological activity of the original oil, and, as it forms usually about 1 per cent., the latter represents a concentration of the active principle a hundred fold.

Scheme of Separation

1 litre cod liver oil.
- Saponification by boiling alcoholic alkali
  - Soaps (inactive)
  - 10 g. unsaponifiable matter (active)
    - Crystallisation and precipitation with digitonin
      - 5 g. cholesterol (inactive)
      - 5 g. active oil I
        - distilled in superheated steam
          - Inactive residue (resins, etc.)
          - Active oil II
            - distilled in high vacuum
              - Fraction 1 b.p. 100
              - Fraction 2 b.p. 220–230/2 mm.
              - Fraction 3 b.p. 250–260/2 mm.
              - Fraction 4 b.p. 260–300/2 mm.

Now, this fraction, if prepared from oils of good quality, contains no trace of iodine, whereas from its method of preparation it can contain no fatty acids. Hence this discovery disposes once and for all of the two theories referred to earlier regarding the nature of the substances responsible for the therapeutic action of cod liver oil.

Chemical Nature of Vitamins in Cod Liver Oil.—What then do we know regarding the nature of the active principle, or principles, for it is likely that there are more than one? In the first place, since they are apparently organic in nature and do not belong to any of the main classes of organic foodstuffs, proteins, carbohydrates and fats, we term them vitamins. Recent work by McCollum and his colleagues make it appear probable that at least two distinct substances of this class are present in cod liver oil. One of these, termed vitamin A, is essential for the normal growth and health of the higher animals, whilst another, the antirachitic vitamin, which can

be labelled vitamin D, plays an indispensable rôle in the normal process of bone formation. Deprivation of both factors causes an animal to show stunted growth with lowered resistance to disease and may induce the condition known as rickets. Chemically, both factors are as yet unidentified, but work is proceeding vigorously in the direction of establishing their nature, as the appended scheme of separation will show (see p. 929).

The vitamins are found in Fraction III. This fraction consists mainly of an unsaturated alcohol of molecular weight about 350. It is too early to say whether the alcohol is one or other of the vitamins, or whether the latter are merely associated with this fraction. The active substance will survive acetylation, benzoylation and hydrogenation of the alcohol present in Fraction III, but they are liable to inactivation by oxidation. They contain only carbon, hydrogen and oxygen. There are reasonable hopes that the nature of the vitamins in cod liver oil will soon be ascertained from the continuation of the chemical studies now in progress.

The mere discovery that there are certain vitamins in cod liver oil would not, however, explain the almost specific action of cod liver oil in benefiting nutrition, for numerous other oils and fats, butter fat, beef fat, etc., have also been shown to contain the same active substances. The reason for the outstanding position of cod liver oil was, however, made clear when Zilva and Muira (*Lancet*, 1921, **15**, 422) demonstrated that it contains the vitamins in far higher concentration than any other types of oil or fat; in some cases examined they found the growth promoting power of cod liver oil to be about 250 times that of butter.

It is interesting in this connexion to read in one of the old treatises on the treatment of rickets published early in the last century, the statement that butter will affect the same improvement as cod liver oil, but to do so very much larger quantities must be employed.

Origin of Vitamins in Cod Liver Oil

It may be asked why cod liver oil should be so rich a source of these vitamins, and why different samples of the oil should show differing potency. Obviously, these questions can only be answered by studying the life history of the cod, and by ascertaining why the vitamins are stored in the liver. To do this, and to study the secondary problem of the influence on the vitamins of the methods employed to extract the oil and refine it, Dr. Zilva and I made an examination on the spot of the cod liver oil industries in Norway and Newfoundland, the two chief centres in the world from which supplies of medicinal oil are derived. As a foundation for our enquiry we know that other species derived the vitamin from their food; thus, the vitamins in the fat of cow's milk had been shown to be derived largely from the green foods eaten by the cow. Now the cod and other fishes of his tribe, the gadoids, are carnivorous, but if you trace back the ultimate origin of their food it is found to be minute marine plants termed diatoms. By obtaining one species of these organisms in fine culture and by growing them in artificial sea water in the laboratory, we were able to show that from simple inorganic substances and the energy derived from sunlight they can elaborate amongst other substances the growth-promoting vitamins (*Biochem. J.*, 1922, **16**, 482). Here, then, would appear to be the origin of the vitamins which one seeks when purchasing a bottle of cod liver oil over the counter of the chemists' shop or drug store. There are, however, many steps between the synthesis of the vitamin by the microscopic green plant in the sea and its storage in the liver of the cod. We have been able to trace the intermediate steps by studying the food of the cod. Cod usually feed on small fish, particularly the capelan (*Mallotus villosus*), crustaceans and squid. The caplin and many other small fish are known as plankton-feeders, that is, they live on the swarms of minute animals of many types which constitute animal plankton. Other species eaten by the cod, whilst not themselves plankton-feeders, are found to live on species which are. Thus indirectly the cod is also nourished on animal plankton, which we have found to be very rich in vitamins. In turn, the minute crustaceans, larvæ, worms and decapods, etc., which constitute plankton, feed largely on diatoms, and thus we link up our chain of vitamin transference from the diatom to the liver of the cod (Drummond and Zilva, *Biochem. Jr.*, 1922, **16**, 518).

Cause of Variations in Vitamin Value of Cod Liver Oil

When samples of cod liver oil are tested for vitamin activity it is soon apparent that considerable variations occur, although the poorest specimens we have examined are generally at least ten times superior in this respect to the best dairy butter. It first occurred to us that the variations might reflect changes caused by the manufacturing processes, particularly in view of the somewhat general belief that the modern almost colourless medicinal oils are inferior in therapeutic value to the dark brown oils which were sold years ago.

Manufacture of Cod Liver Oil

The crude golden yellow or dark brown oils, which are now seldom used except for leather dressing, built up the reputation of cod liver oil. They were prepared by processes centuries old and consisting either of allowing the livers to rot in vats exposed to the air until the oil floated to the surface and could be separated, or of cooking the livers in pans over the open fire until the oil could be skimmed off. Both processes yielded unpalatable products well remembered by many people still alive as associated with sad hours of childhood.

A great advance was made when about 1850 an Englishman introduced the steaming method into Newfoundland, and Peter Möller a similar method into Norway. From this time the preparation of cod liver oil has been made the subject of considerable care. The absolutely fresh sound livers are now cooked by direct or indirect steam heating and the oil separating from the tissues is skimmed off. Second fractions are often prepared by reheating or pressing the residue from the fresh separation.

The colour of the oils thus prepared vary from almost colourless to pale golden yellow.

The separated oils are usually clarified and refined by cooling to 10° C. and filtering off the "stearin" which separates out. This yields the clear, bright, pale oils used generally for medicinal use at the present time. Dr. Zilva and I have ascertained that in the preparation of these oils of high quality there is no appreciable loss of vitamin, and that there is no foundation for the belief that the crude brown oils used so mercilessly by our grandparents were superior to those that the rising generation has to endure. On the other hand there is some evidence that the greater opportunity for oxidative changes which was presented during the older processes may have led to some loss of physiological activity (*J. Soc. Chem. Ind.*, 1922, **41**, 280 T). Furthermore, we have recently found that the careful preparation of emulsions of cod liver oil usually has very little destructive action on the vitamins (*J. Soc. Chem. Ind.*, 1924, **43**, 236 T).

If, then, the variations in vitamin activity are not due to conditions of manufacture, we must assume that they occur in the livers of the fish. Direct trial confirms this assumption. It was necessary, therefore, to investigate how the variations arise.

Life History of the Cod

To do this it was necessary to study the life history of the cod which has been worked out with such care by Hjort for the Norwegian waters. There are two distinct fishing seasons in Norway during which cod liver oil is extensively prepared. The first, lasting approximately from February to May, is centred round the Lofoten Islands and coincides with the time that the mature cod are spawning on the shallow sandy banks round those islands. The fish caught are practically all cod (*Gadus callarius*) and during the spawning period they take little food. As Hjort showed, the ripening of the eggs is marked by the passage of considerable amounts of reserve foodstuffs, particularly fat, from the liver to the developing ova. The eggs of the cod are very rich in vitamins (Hjort, *Proc. Roy. Soc.*, 1922, **93**, 440), and it might be expected that this would materially reduce the concentration of these substances in the liver. Actually we do find the oils prepared during this season tend to be lower in vitamin value than those prepared at other seasons, but we are not yet satisfied that we have the full explanation of the variations.

After spawning, the surviving fish, which are now "spent," migrate northwards to feed after their period of fasting. They are attracted to the north by large shoals of the caplin, a small fish about the size of a sardine, which migrate from the polar seas to the north coast of Norway about May to spawn. Following in their wake and devouring them in enormous numbers come huge numbers of cod, ling, haddock, pollack and other gadoids, and which are reinforced by the "spent" fish arriving from Lofoten. The migration of pursuers and pursued proceeds eastwards along the Finmarken coast until by July or August they reach Murmansk, later turning northwards into polar waters. During the time they are off the coast, active fishing is in progress and much oil is prepared. It is, however, seldom made solely from cod but from the livers of the mixed gadoid fishes caught. This is no disadvantage, however, since we have convinced ourselves that the oils yielded by the livers of the other fish—haddock, ling, pollock, coal-fish—are at least equal to cod liver oil in potency. The average vitamin value of the oil yielded during this period, often termed Finmarken oil, when the fish are actively feeding is higher than that of Lofoten oil, and we are inclined to attribute this to the food. In a recent re-examination of this question (Zilva, Drummond and Graham, *Biochem. J.*, 1924, **18**, 178) we have again been led to conclude that the chief cause of the variation in the vitamin content of cod liver oil lies in changes in the nature of the food supplies.

In Newfoundland the oil is seldom prepared in any quantity from fish caught during the spawning, with perhaps a second and less important spawning period in September, which takes place on the Banks in June, according to the observations of our colleague Mr. Graham, B.A. The fish are usually actively feeding either on caplin or squid when caught and the livers used for oil manufacture. We were not surprised therefore to find that the Newfoundland oils show a high average nutritive value (*J.*, 1923, 185 T).

Role of Vitamin A in Animal Nutrition

The vitamins we have been referring to appear to be necessary for the normal growth and nutrition of animals higher in the evolutionary scale than the amphibia. Certainly in the case of fish the considerable stores laid up in the eggs are utilised during the development of the larval fish (Coward and Drummond, 1920, **16**, 631), and the subsequent growth during the post-larval condition is dependent on adequate supplies of food containing these substances being available. The mammals pass supplies of the essential vitamins on to their young by way of milk, and unless the food supply of the lactating female contains adequate sources of these substances there is danger that the young will suffer from the qualitative deficiency of her milk.

Thus it has been shown that on certain rations deficient in the vitamins A and D, the milk yielded by cows whilst being both adequate in amount and satisfactory when analysed by the usual chemical methods, may, nevertheless, when tested biologically, be found seriously deficient in the growth-promoting and antirachitic powers (Drummond, Coward and Watson *Biochem. J.*, 1921, **15**, 540; Kennedy and Dutcher, *J. Biol. Chem.*, 1922, **50**, 339). This fault may be quickly corrected either by supplementing the deficient ration with fresh green fodder, or by administering a relatively small ration (2—4 oz.) of cod liver oil daily to the cow (Drummond, Coward, Golding, Mackintosh and Zilva, *J. Agric. Sci.*, 1923, **13**, 144; *ibid.*, 1924, in press).

Of the practical employment of cod liver oil as a preventive and curative agent in combating malnutrition and its associated diseases, I do not feel

qualified to speak, as I am not a medical man. The experimental work of Mellanby and of McCollum and the extensive practical studies on rickets and osteomalocia in Vienna carried out by Miss Chick and her colleagues scarcely leave a doubt that in cod liver oil we have a remedy that should enable us to wipe out these disorders.

As yet we are unable to say how the minute amount of certain organic substances present in this oil play a part in bringing about normal bone formation. Many other factors are undoubtedly involved in this complex process amongst which the calcium-phosphorus balance is of obvious importance, but others, such as ultra-violet radiation, play a role which is as yet quite obscure. At one time it was thought that exposure to sunlight or other source of ultra-violet light would cure rickets without the co-operation of the vitamin, but the work of Miss Hume indicates that this is not so, but that the animal can reorganise its calcification with the aid of very much smaller amounts of the vitamin when radiation of the skin is carried out at the same time. Much research is needed to clear up this tangled problem, but whatever fascinating story may ultimately be revealed when the difficulties have been overcome by the workers in laboratory or hospital ward, the fact remains that already our knowledge of the almost specific action of cod liver oil in the prevention and curing of rickets and other diseases which follow in the train of defective nutrition, is sufficient to enable us to reduce enormously the number of lives which are destroyed or damaged by their incidence.

NEW HELIUM PLANT IN WASHINGTON

The U.S. Bureau of Mines semi-commercial helium plant will continue to operate during the time that the Navy's large plant is under construction. This plant, which is to have a capacity of 1,500,000 cb. ft. of gas per day, was designed by the Bureau of Mines, along the lines of the semi-commercial plant. It is estimated that this plant will make possible the production of helium at $30 a 1000 cb. ft. Helium production now is proceeding at a rate in excess of 500,000 cb. ft. per month, the month's output sometimes being as high as 1,000,000 cb. ft. This gas is stored in cylinders, each having a capacity at 1800 lb. per sq. in. pressure of 200 cb. ft. The problem of this type of storage is emphasised when it is considered that 2,150,000 cb. ft. is required to fill the Shenandoah. In view of objections raised to the legislation necessary to the conservation of helium, it is of interest to note that Canada recently adopted a much more stringent leasing act than has ever been proposed in the United States, pending a thorough field survey for helium. The Canadian Government is taking vigorous steps to push its exploration programme.—(*Chem. and Met. Eng.*, Aug. 4, 1924.)

PROGRESS AND PROSPECTS IN CHEMOTHERAPY *

By H. H. DALE, C.B.E., M.D., F.R.S.

INTRODUCTORY

In the mind of every physiologist visiting Toronto to-day one recent advance in our science will certainly be uppermost. We rejoice with our colleagues here in a great achievement which has opened new vistas of knowledge to exploration, has brought relief to unmeasured misery, and has turned the eyes of the world, too often careless of such things, in proper gratitude and well-founded hope to this University and its Medical School. Insulin, and its still marvellous and mysterious action, have held a prominent place in the interest of many of us, myself included, during the past year or two. In one of our meetings, however, we shall have the opportunity of considering the observations and opinions of many who are now working on its properties and their significance, and among them will be some who were associated with its discovery. I have thought it appropriate, therefore, to ask your attention to-day to some recent developments in a widely different field of investigation. The subject which I have chosen presents points of general physiological and biochemical interest, apart from its immediately practical importance for the treatment of disease. It has, further, in one way, a special appropriateness to this year's meeting of the British Association. For our knowledge of an important group of diseases, caused by the parasitic trypanosomes, which have provided the experimental material for a very large proportion of chemotherapeutic investigations, we are in the largest measure indebted to the pioneer work of the distinguished President of the Association, Sir David Bruce.

I THE THEORETICAL ORIGIN OF CHEMOTHERAPY

Chemotherapy may be defined as the specific treatment of infections by artificial remedies. The object of those who study it is to find new remedies which will cure or arrest diseases due to infections, not by alleviating the symptoms or invigorating the patient, but by directly and specifically suppressing the infection. Chemotherapy, in this wide sense, is not entirely of recent growth. When the natives of Peru discovered the value in fevers of the cinchona bark, which the Jesuits brought to Europe in the seventeenth century, they had found a specific remedy for malaria, which is still the best available. Similarly the natives of Brazil had found in ipecacuanha, which reached Europe shortly after cinchona, a remedy for amœbic dysentery better than any other which our modern systematic and scientific efforts have produced. Modern chemistry, indeed, has separated the alkaloids from these drugs, and has made it possible to identify among them the actively therapeutic constituents; Protozoology has revealed the nature of the infections. We know now that cinchona owes its curative action chiefly to

* Presidential Address to Section I (Physiology) of the British Association, Toronto.

quinine and quinidine, and that they act as specific exterminators of the malaria parasites, and not simply as remedies for fevers in general; and we know that ipecacuanha owes its action to emetine and cephæline, and that these act as exterminators of the entamœba causing tropical dysentery, and not simply as symptomatic remedies for dysenteries of any kind. But chemistry has produced no better remedy for malaria than quinine, or for amœbic dysentery than emetine; and the method by which either of these alkaloids cuts short the infection by a particular parasite, the nature of its specific action, remains a fascinating problem.

The modern development of chemotherapy, as a new department in therapeutic science, claiming the co-operation of parasitologists, microbiologists, and synthetic chemists, did not take origin, however, simply from the study of these traditional remedies. It may be regarded rather as an outcome of the study of the natural antibodies. The investigation of these natural antagonists to infection produced a new therapeutic ideal. Not only had they shown themselves to have an intensely specific affinity for the infecting organism of the toxin which caused their production: they were also perfectly harmless to the patient, behaving, in relation to his organism, as normal constituents of his body fluids and tissues. Ehrlich aptly compared them to magic bullets, constrained by a charm to fly straight to their specific objective, and to turn aside from anything else in their path.

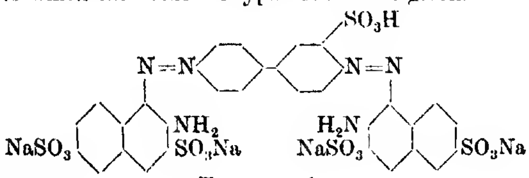
Of the artificial remedies, on the other hand, which man had empirically discovered, even of drugs like those just mentioned as being specific for certain infections, the best that could be hoped was that they would eliminate the parasite before they poisoned the patient. And thus, when the limitations of natural immunity were becoming clearer: when it was realised that to certain forms of infection, several of which had proved to be infections by protozoa, the body was unable to produce antibodies of sufficient potency to eliminate the infection and leave the patient immune; the question arose whether, with the new and growing powers afforded by synthetic chemistry, man could not so far rival Nature's achievements as to produce, in the laboratory, substances specifically adapted to unite with and kill the protoplasm of these parasites, as the natural antibodies united with that of others, and to leave the tissues of the patient similarly unaffected. The ideal of this new and systematic Chemotherapy, as the imaginative genius of Paul Ehrlich conceived it, was to be the production by synthesis of substances with a powerful specific affinity for, and a consequent toxic action on, the protoplasm of the parasites, and none for that of the host—of substances, to use Ehrlich's terminology, which should be maximally parasitotropic and minimally organotropic.

I want to invite your attention to-day to the results which, during the last twenty years, have been produced under the stimulus of this bold conception; not, indeed, to attempt a survey or summary of all that has been done, but, in the light of a few of the suggestive facts which have emerged, to consider how far this hypothesis has justified itself, and whether it can be accepted as a safe guide to future progress, as it has undoubtedly provided the initiative and working basis for much of what has been accomplished hitherto. Before we deal with some of the actual results obtained, it may be well to consider a little more closely what Ehrlich's working hypothesis involved. The problem was to discover, by chemical synthesis, a compound which, in virtue of its chemical structure, should have a maximal affinity for the protoplasm of a microscopic parasite, such as a trypanosome, and a minimal affinity for that of the host's body cells. These affinities were pictured by Ehrlich, in the terms of his side-chain theory, as determined by certain side-chains of the complex protein molecule, or chemoreceptors, which endowed the protoplasm with specific combining properties. When it is remembered that knowledge of the chemistry of the protoplasm of a trypanosome is almost nil, and that what little we do know suggests that it is very similar to that of our own cells, it will be admitted that the enterprise was one calling for scientific courage and imagination in the highest degree. Complete failure would not have been surprising: the matter for surprise, and for admiration, is that so large a measure of practical success should, at the end of two decades, already claim record.

II Trypanosomes and Spirochætes

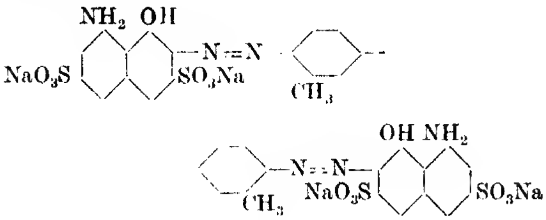
i. *The action of dyes and analogous compounds*

The investigations leading, in the last few years, to a clear promise, at last, of the successful treatment of the diseases in man and animals due to infections with trypanosomes, had at least two different starting-points, the action of dyes and the action of arsenic. Ehrlich's early interest in the synthetic dyes, and his observations of the curiously selective distribution which they often exhibited among the cells and tissues of the body, naturally suggested the possibility of finding, in this group, a substance which would selectively fix itself to the parasite and poison its protoplasm, without injuring that of the host. The technique developed by Laveran and Mesnil, by which a particular strain of trypanosome could be passed through a series of mice or rats, and produce an infection of standardised type and virulence, enabled the effect of a large selection of dyes to be investigated, with the view of finding one which would favourably influence the infection. A starting-point having been obtained, the resources of synthetic dye production were available to produce an indefinitely long series of derivatives and modifications of the active compound, each to be tested in its turn. In this way Ehrlich and Shiga arrived at a substance which gave experimental promise of curative value, a benzidine dye to which the name "Trypan red" was given.



Trypan red

Two years later, Mesnil and Nicolle, proceeding further along the same path, described an even more favourably active blue toluidine dye, "Trypan blue."

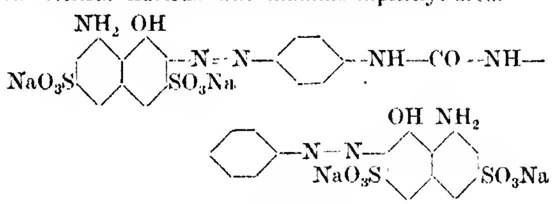


Trypan blue

This is the only one of the dyes which has hitherto had a genuine practical success in the treatment of a protozoal infection, not indeed by a trypanosome, but by an intracorpuscular parasite of the genus Piroplasma, which infects dogs and cattle. This successful application of trypan blue to an animal disease has a special interest for us to-day, in that it resulted from the joint labours of last year's President of this Section, Professor Nuttall, with a Canadian collaborator, Dr. Hadwen.

We may turn aside at this point to enquire how far the results even of these earlier investigations corresponded with the theory which gave them their impetus. Did these dyes really act by selectively staining and killing the parasites, and leaving the host's cells untouched? The evidence was certainly not in favour of such a view. Ehrlich and Shiga themselves observed that Trypan red, even in relatively high concentrations, was practically innocuous to the trypanosomes outside the body. The trypanosomes, like other cells, were not stained by the dye until they died, and there was no clear evidence that they died sooner in the Trypan-red solution than in ordinary saline. Again, Trypan-red cured an infection by the trypanosome of "Mal de Caderas" (*T. equinum*) in the mouse, but not the same infection transferred to the guinea-pig, rat, or dog; nor did it cure an infection with the trypanosome of Nagana (*T. brucei*) in mice. Now, to explain such a difference by stating that the affinity of Trypan red for *Trypanosoma equinum* was much higher than its affinity for the tissues of the mouse, but not than its affinity for those of the rat, would be merely to restate, in terms of the theory, the observed fact that the mouse was cured while the rat was not; and the lack of direct affinity for the dye shown by trypanosomes outside the body made such an interpretation in any case unsatisfactory. One point, however, appeared very significant, and it is met repeatedly in studying the action of effectively chemotherapeutic substances, namely, that the trypansomes treated with the dye *in vitro*, though neither obviously stained nor visibly harmed, had lost their power of infection, and died out promptly if introduced into the body of a mouse. Under such conditions only minimal traces of the dye are introduced into the animal, and we are left with a series of alternative possibilities. It is possible that sufficient dye has been taken up by the trypanosomes to kill them eventually, the period of survival *in vitro* being inadequate to display its action; or that Trypan red is converted by the influence of the body fluids and tissues into something which is effectively lethal for the parasite; or, again, that the effect of the drug is not directly to kill the trypanosomes, but, leaving their individual vitality and motility unimpaired, so to modify them that they have lost the power of rapidly reproducing themselves and invading the fluids and tissues of the mouse's body—in other words, have lost that complex of adjustments to the various factors of the host's natural resistance which we crudely summarise as "virulence." Such possibilities involve either storage or modification of the dye by the host's tissues, or their essential co-operation in its curative effect.

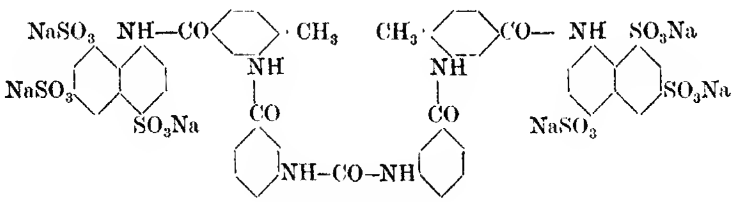
One other active dye must be mentioned as providing the link with a recent, most important advance. Mesnil and Nicolle in 1906 made some promising experiments with a dye, Afridol violet, which differed from any previously tested, in that its central nucleus was diamino-diphenyl-urea.



Afridol violet

From this time onwards there was no further public indication of progress along these lines until 1920, when Händel and Joetten published the results obtained with a remarkable substance which, as the result of some fifteen years of continuous work by their scientific staff, had been introduced by the great dye and chemical firm of Bayer. This substance, which is not a dye, but the colourless, water-soluble salt of a complex sulphonic acid, has hitherto been known as Bayer "205," and, for reasons which need not concern us, the firm decided not to publish its formula. To students of their patent specifications, however, it seemed pretty certain that it would prove to be one of a long series of compounds, formed of chains of aminobenzoyl radicles, united by amide linkages, with a central urea linkage, like the dye last mentioned, and terminal naphthylamine sulphonic acid groupings. A number of these substances, having no diazo-linkages, were not dyes, but there was no indication as to which constitution, out of an immense number possible, would prove to be that of the remarkable substance numbered "205." There is a reasonable probability that its identity has now been settled by the recent work of Fourneau and his co-workers in the Pasteur Institute, who made and investigated an extensive series of compounds of this general type, and found one, which they numbered "309," which conspicuously excelled all others, even those closely related to it, in the favourable ratio which it displayed, between a just toxic dose and that which caused a trypanosome infection in mice to disappear.

As in the case of "205," the ratio, the "chemotherapeutic index" of Ehrlich, was found by Fourneau, in some experiments with his compounds, to be well over 100. At least it may be said that, if M. Fourneau has not identified Bayer "205," he has discovered another compound having very similar, and probably as valuable, properties.



Fourneau's "309" (possibly identical with Bayer 205")

The most remarkable property of "205" is the long persistence of its effect. A dose injected into a mouse, a rabbit, or a rat will not only free the animal, if already infected, from trypanosomes in a few days, but will also render it resistant to such infection for a period of weeks or even months. During that period its serum, or extracts from certain of its organs, exhibit a curative action if injected into another animal infected with trypanosomes.

Though there seems no reason to doubt that this substance has cured a number of cases of African sleeping-sickness in man, even some in which the disease was well advanced and in which all previously known remedies had failed, the mode of its action still presents a number of attractive obscurities. Like many other remedies which are experimentally efficient when injected into the infected animal, it has little or no obvious action when directly applied to trypanosomes *in vitro.* The paradox is, perhaps, less than usually significant in this case, since the action in the animal is delayed, a period of a few days elapsing before the trypanosomes begin to disappear from the blood. We might suppose that the action is too slow to be recognised during the period of survival of the parasites outside the body, or that it affects not the individual vitality of the trypanosomes, but their power of reproducing themselves. The latter idea is supported, as in other cases, by the fact that trypanosomes treated with the drug *in vitro*, or taken from an injected animal before the curative effect has become manifest, fail to infect another animal. It is contradicted, however, by the observation that the trypanosomes, just before the curative action begins, show not a depression, but a stimulation of reproductive activity, division forms becoming abnormally common. Is it that during or immediately after division the parasites become specially liable to the action of the drug? It may be so; but one thing seems perfectly clear, namely, that the action is a very complex one, involving the co-operation, in some way, of the host. For here again it is found that the curative action, on infections by the same strain of trypanosomes, varies enormously with the species infected, a mouse beiug cured with ease, an ox or a horse with difficulty or not at all. A curious fact is that the rapidly progressive and fatal infections produced in mice by certain pathogenic trypanosomes are easily and certainly cured, while the apparently harmless natural infection, seen in many wild rats, by *T. lewisi* is not affected at all. Then there are some curious records of treatment in man, in which the symptoms of sleeping-sickness have disappeared, but the trypanosomes are still found in the cerebro-spinal fluid, suggesting that, though the parasites have not been killed, they have lost their virulence and their power of invading the brain substance.

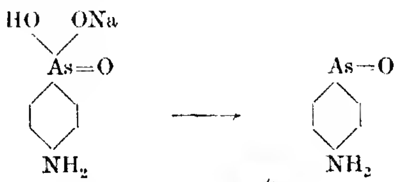
The features of the action of this remedy, however, which have most interest for the physiologist and the biochemist are those related to the long persistence of its effect. "205" has a large molecule, but it is extremely soluble in water, and diffusible through collodion membranes. How, in such circumstances, can we explain the persistence of its sterilising and prophylactic action for months after an injection? At first sight one is tempted to regard it as incredible that a substance with these properties should persist in the body for such a period, and to suggest that the action must be due to its stimulation of the body to form its own protective substances. This possibility, however, seems to be excluded by the fact that the serum of the protected animal does not lose its curative properties if heated. On the other hand, there have recently appeared, some of them only in preliminary abstract, a series of highly suggestive observations, indicating that "205" has properties of entering into a combination of some kind with the serum proteins. After standing for an hour or two in serum, "205" no longer passes into an ultra-filtrate through collodion, and if the proteins are coagulated by heat is not to be found in the filtrate. The proteins of the blood, moreover, are stated to lose many of their characteristic properties by entering into this combination, the blood losing its normal power of clotting, and the serum proteins not being precipitated by mercury salts or tannin.

It would be both useless and presumptuous for a mere onlooker to speculate in detail on the significance, for the curative action of "205," of properties which are only now beginning to be investigated. One conclusion, however, I think, we are entitled to draw. It is sufficiently evident that here is no question of a substance curing simply on

account of its affinity for parasites and lack of affinity for the host's tissues. What direct action on the parasite "205" itself may possess has still to be demonstrated: we may feel reasonably certain, on the other hand, that its affinities for the constituents of the host's blood and tissues play an important part in its remarkable and peculiar curative properties.

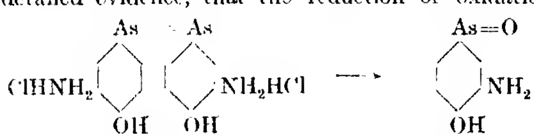
ii. *Derivatives of Arsenic*

In the case of the other series of investigations which I mentioned, that dealing with the organic derivatives of arsenic, we find again many difficulties, in the way of simple theory, of a cure due to distribution by chemical affinities. None of the compounds of this series, which have reached practical trial and success in the treatment of spirochætal or trypanosomal infections, atoxyl, salvarsan, or tryparsamide, has a directly lethal action on the parasites in dilutions at all comparable to those which can be safely and effectively produced in the body of the host. The paradox of this direct inertness of atoxyl, the starting-point of the series, seemed to be explained when Ehrlich showed that its reduction to the corresponding arsenoxide produced a substance with an intense directly lethal action on trypanosomes. Similarly the partial oxidation of salvarsan, to the corresponding arsenoxide, produced a substance having



"Atoxyl" Arsenoxide from "Atoxyl"

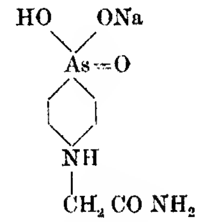
the intensely lethal action on spirochæts or trypanosomes *in vitro*, which salvarsan itself conspicuously and paradoxically lacked. In these cases, we may make the supposition, which Voegtlin and his co-workers, especially, have recently supported by detailed evidence, that the reduction or oxidation



"Salvarsan" Arsenoxide from "Salvarsan"

effected by contact with the tissues is the essential preliminary to the curative action; a supposition which, it will be noted, again introduces the host as an essential participant in the cure. The fact, that the administration of these relatively inactive predecessors is therapeutically more effective than the injection of the directly active oxides derived from them, would then be explained on the assumption that the slow liberation of these latter in the body, at a rate which never produces a high concentration, provides the optimum condition for their persistent action on the parasites, without danger to the host. This slow and persistent liberation of the directly active substance would be favoured by the physical properties of salvarsan, which at the reaction of the body is practically insoluble, and must be rapidly deposited after injection.

In their recent work on the action of Tryparsamide the compound,



Tryparsamide

prepared by Jacobs and Heidelberger at the Rockfeller Institute, which has shared with Bayer "205" the credit of making the eventual conquest of African sleeping-sickness a hopeful possibility, Brown and Pearce find it necessary to introduce yet other considerations to explain its effects. Tested by Ehrlich's therapeutic index—the ratio between the lowest curative and the highest non-toxic dose—it gives a relatively unfavourable figure. Brown and Pearce practically abandon the attempt to account for its action on the supposition that it directly kills the parasites, and attribute its value largely to its power of penetrating easily into the tissues and reinforcing there the processes of natural resistance.

iii. *Action of Bismuth*

Another conception of the mode of action of these arsenical remedies, also involving a direct participation in the host's tissues, was put forward by Levaditi. He found that from atoxyl a directly parasiticidal preparation could be obtained, by incubating it with an emulsion of fresh liver substance. As the first step, therefore, in the curative action of atoxyl, he postulated a combination of its reduction product with some constituent of the liver or other tissue, giving rise to the essential curative complex, which he named "trypanotoxyl." Levaditi's observations were explained by Ehrlich and Roehl as due simply to the reducing action of the liver substance on atoxyl; but it would be difficult to apply this explanation to the quite recently published observations by Levaditi and his colleagues, on the mode of action of bismuth in curing spirochætal infections. A sodium potassium bismuthyl tartrate—a bismuth analogue of tartar emetic—had been found to have valuable curative properties in syphilis and other spirochætal infections. Later, various other bismuth salts, bismuth suboxide, and even finely divided metallic bismuth, were found to produce similar effects. According to Levaditi and Nicolau, these preparations have, by themselves, a relatively weak action, or none at all, on the spirochæts outside the body. If they are mixed, however, with a cell-free extract of liver,

which is itself harmless to spirochæts, the mixture, after incubation, acquires a potent spirochæticidal action. The possibility of a mere reducing action of the liver extract seems here to be excluded, since bismuthous oxide, or metallic bismuth itself, yields a spirochæticidal mixture, containing Levaditi's hypothetical "bismoxyl," when incubated with the liver extract. If these observations are confirmed, there will be a strong indication that some cell-constituent enters into the composition of, or is essential to the formation of, the directly active substance from any of the derivatives of arsenic, antimony, or bismuth, as a preliminary to its action on an infection due to a trypanosome or a spirochæt. Again we have evidence of an organotropic property of the remedy, as an essential condition of its activity.

v. *Resistant Strains of Trypanosomes*

In the phenomena of the acquisition of resistance, by a strain of infecting trypanosomes to a particular curative drug, discovered and largely worked out in Ehrlich's laboratory, we meet again with facts which can only with the greatest difficulty be reconciled with the assumption that the drug directly attacks the parasites. It was found, for example, that if a mouse infected with trypanosomes received an incompletely effective series of doses of atoxyl, the trypanosomes appearing in the blood at each relapse were more and more resistant to the drug, until they could not be caused to disappear by any dose of atoxyl which the mouse would tolerate. The strain, having once acquired this resistance, would retain it, on passage through an indefinitely long series of mice, without further treatment. Mesnil and Brimont, however, made the remarkable observation that, if the strain of trypanosomes was transferred to a rat, it immediately became in that animal susceptible again to treatment with atoxyl, remained so as long as it was kept in rats, to reacquire its old resistance to atoxyl as soon as it was retransferred to mice. Such a fact seems to be not at all explicable on the theory that the directly active agent, to which the trypanosome becomes resistant, is a mere reduction product of atoxyl: it is much more easily reconciled with a mechanism such as that described by Levaditi, in which a constituent of the host's tissues enters into the formation of the trypanocidal substance. We can imagine the trypanosome becoming immune to Levaditi's mouse-trypanotoxyl, and remaining susceptible to the corresponding rat-product.

The whole question of this acquired resistance of the parasites to the action of curative drugs bristles with points of difficulty and interest. Ehrlich attributed the sensitiveness of the parasite, for a particular curative agent, to the possession by its protoplasmic molecule of a special form of side chain, or "chemoreceptor," which determined its affinity for that agent. When the trypanosome became resistant, it was simple to suppose that it did so by losing the appropriate chemoreceptors; an atoxyl-resistant trypanosome, for example, had lost its atoxyl receptors. Apart from the objections already mentioned, this conception met a new difficulty, when in Ehrlich's laboratory it was found that the resistance was by no means as rigidly specific as it first appeared to be. Not only imperfect treatment with atoxyl, but treatment with a particular group of dyes, having no kind of chemical relation to it, was found to produce a race of trypanosomes resistant to atoxyl and to other arsenical derivatives. To suggest that the chemoreceptors for arsenic and for these dyes are identical is merely to restate the fact of this reciprocal action in terms having no definite meaning. Obviously no more precise conception as to its significance can be formed until we know something more of the conditions on which resistance and susceptibility depend. A recent suggestion by Voegtlin has interest in making, at least, an attempt at interpretation in more definite biochemical terms. Voegtlin and his co-workers point out that arsenious oxide and its derivatives readily combine with substances containing a sulphydrile grouping, and find that the toxic action of the organic arsenoxides, on trypanosome and mammal alike, is depressed by the simultaneous injection of excess of various sulphydrile compounds.

$$R{\cdot}As = O + \frac{HS{\cdot}R}{HS{\cdot}R} = R{\cdot}As\begin{matrix}\diagup S{\cdot}R \\ \diagdown S{\cdot}R\end{matrix} + H_2O.$$

III Suggested Reaction of an Arsenoxide with a Sulphydrile Compound

The work of Hopkins, showing the importance of one such sulphydrile compound, reduced glutathione, in the hydrolytic oxidation-reduction processes of the cell, suggests to Voegtlin that a combination with such groups, and consequent suppression of this vital function, may explain the toxic and curative actions of the arsenical derivatives, and that a formation by the trypanosome of the sulphydrile compound, in excess of its vital need, may be the basis of acquired resistance. If certain dyes similarly affect this cellular oxidation system, the production under their influence of strains of trypanosomes resistant to arsenic would also be explained. So stated the suggestion leaves many aspects of the problem still unconsidered: but it may at least be allowed the merit of an attempt to interpret the action of these drugs in terms of known biochemical facts.

IV Emetine and Dysentery

To turn to another example of a chemotherapeutic problem, I may mention briefly some results obtained, some years ago, by Mr. Clifford Dobell and myself, in an attempt to explore the curative action of emetine and the other alkaloids of ipecacuanha in amœbic dysentery, with a view to finding a more effective treatment. At the time when we took up the problem it seemed simple. Rogers had recorded that the amœbæ obtained from a case of amœbic dysentery, and treated *in vitro* with emetine, were rapidly killed by the alkaloid in dilutions as high as one part in 100,000. This seemed to explain the action of emetine as a simple and direct one on the parasites, and to provide a rapid method for testing

a series of compounds for their therapeutic possibilities. We failed, however, as other observers before and since have done, to confirm the observation: on the contrary, we found that the dysenteric amœbæ, obtained from cats secondarily infected, or, in a control observation, directly from man, were surprisingly insusceptible to the action of emetine, living for hours in concentrations much greater than the highest which they would tolerate of other alkaloids, which had no curative action in dysentery. One of the other natural alkaloids of ipecacuanha, methyl-psychotrine, and certain artificial derivatives of emetine, were much more effective in killing the amœbæ in the test tube, and at the same time were practically devoid of the characteristic toxicity of emetine and cephæline for mammals and for man. Here, on the classical assumption of chemotherapy, should have been ideal remedies for amœbic infection—substances much more parasitotropic and much less organotropic than those already known to be effective. Yet each of them in turn when administered to patients suffering from amœbic dysentery, in doses much larger than those in which emetine could be tolerated, produced no effect whatever on the dysentery, which promptly cleared up when emetine was subsequently given. Among the members of this group of alkaloids which were tried, the curative effect seemed to be proportional rather to their toxic and nauseating action on the patient, than to their lethal action on the isolated amœbæ. Yet emetine and cephæline are not mere symptomatic remedies; they definitely stop the progress of infection by the amœbæ, and, properly administered, eliminate them altogether from the body.

Yet another puzzling observation, made by Dobell and myself, was that an amœbic infection which readily yielded to treatment with emetine in man, was entirely uninfluenced by emetine when transferred to the cat. In no way is it possible to account for these facts without admitting a co-operation of the patient's tissues in the curative action; nor, with that admission, can we do more than consider possibilities. We only know that the truly parasitic *Entamœba histolytica*, which cannot live without invading the tissues, can be checked in this invasion and eliminated from the body by administering emetine, while other Entamœbæ, which live on fæcal debris, remain unharmed. Whether the tissues are so altered that the amœbæ cannot invade them, or the amœbæ, without being directly killed, are so weakened in virulence that they cannot invade the tissue and obtain their food, but succumb in face of the normal resisting powers of the host, are possibilities on which we can only speculate, and no method of bringing them to the test of experiment has yet been found.

The work of Morgenroth and his co-workers, extending now over more than a decade, has again led them to emphasise, in connexion with the curative action of substances which they have examined, a fixation to the cells and tissues of the host, a definitely organotropic property, as an important factor in the effect. Two examples may be mentioned.

V Quinine and Malaria

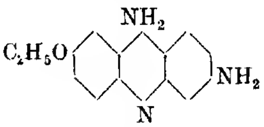
One of the earliest of chemotherapeutic discoveries, that of the cure of malaria by quinine, had never been satisfactorily explained. There was no evidence establishing even a probability that quinine, in such concentrations as can be tolerated in the blood of the living subject, would directly kill the malarial plasmodia, especially if these were partly screened from its action by their position in the interior of the red corpuscles. Morgenroth, from the results of his determination by biological methods of the distribution of quinine in blood, is led to the conception of quinine as acting on malaria, in virtue of its fixation by the red corpuscles, either killing the trophozoites in their interior, or blocking the entry into them of the merozoites of the asexual cycle. On this latter supposition, it will be seen that quinine would act, not by killing the malarial parasites, but by rendering the blood unfitted for their multiplication. They are supposed to fall a prey to the natural defensive substances in the plasma, because a film of quinine denies them access to the red corpuscles, in the interior of which they could continue their development in safety. There are discrepancies between Morgenroth's determinations of the distribution of quinine in favour of the red corpuscles, and those obtained by direct chemical means, which would still need to be reconciled, before either theory of the curative process in malaria could be fully accepted. Meanwhile, these suggestions are of interest, as another example of the need found, more and more, by workers in this field, to regard an organotropic property of a drug, not as detrimental to its curative action, but as an essential factor in the chemotherapeutic process.

VI Remedies for Bacterial Infections

This same property, of fixing themselves to the red blood corpuscles or to the connective tissue, has been observed by Morgenroth and his co-workers with the higher homologues of quinine, ethylhydrocupreine ("optochin"), and octylhydrocupreine ("vuzin"), and with the dyes of the acridine series, with which they have obtained promising results in the treatment of bacterial infections. In the treatment of pneumococcus infections by optochin several factors, other than those of immediately lethal action of the alkaloid on the pneumococci, appear to be concerned. Evidence was obtained by Moore, for example, which suggested that the defensive reaction of the host was an essential factor in the cure, optochin, in doses inadequate to kill the pneumococci, rendering them liable to the action of specific antibodies; and some experiments of Felton and Dougherty suggest that an excessive dose of an alkaloid of this class, by suppressing the natural defensive reaction, may even allow the fatal spread of an infection which a lower dose would cure. Morgenroth, on the other hand, emphasizes the part played by the organotropic properties of optochin and vuzin, in enabling the red corpuscles to act as carriers of the drug to the point of action, and the connective tissues to form local depots of it.

An acridine dye, named Trypaflavin, was under study in Ehrlich's laboratory in 1914 as a trypano-

cidal remedy, and was found during the war, by Browning and his co-workers, to have valuable properties as an antiseptic for infected wounds and mucous membranes, for which, under the name "Acriflavine," it is still used. Since the war, other dyes of this series have been investigated by Morgenroth and his school, and one of them, called "Rivanol," is stated to be particularly effective as a tissue antiseptic, especially in conditions of spreading infection due to streptococci.



"Rivanol" (2-ethoxy 6, 9 diamino acridine)

In the case of "Rivanol" also, evidence has been brought forward that it is fixed by the red corpuscles and the subcutaneous tissues, protected thereby from excretion, or held at the point where its curative action is required. From these body cells it is suggested that the dye is gradually given up to the cocci, on which its action is exerted, by a process called "transgression" by Morgenroth. This is a process by which a substance is passed from one medium to another, when both have strong affinities for it, through a layer of an intervening medium for which it has no affinity, and in which it may be almost insoluble. In this process of depot formation, and gradual liberation of the active substance, we are concerned with a phenomenon which certainly has a widespread importance for chemotherapeutic action. We have earlier seen evidence of such fixation and gradual release in the cases of Bayer "205" and Salvarsan.

Another suggestive feature of the action of "Rivanol" on streptococcal infections, is that such organisms as escape the immediately lethal effect of the dye appear to have lost their hæmolytic properties, and to have been modified into a relatively avirulant strain.

VII Conclusion

We have considered but a few examples of the directions in which chemotherapeutic investigation has proved practically fruitful, including some in which it shows, at the moment, the most hopeful signs of progress. If one considers any one group of investigations by itself, one may easily feel, at the same time, elated by the practical success obtained in the cure of some infection which, but a few years ago, seemed beyond the reach of treatment, and depressed by the disharmony between the results of experiment and the theoretical conceptions, hitherto available, of the nature of the chemotherapeutic process. Some of the most notable practical triumphs in this field have resulted, not from experimental investigations based on the theory, but from an almost empirical trial, on human patients suffering from one type of infection, of a remedy which had experimentally shown promising results in infections of a different and sometimes of a widely different, type. The partial success of tartar emetic in trypanosome infections might have justified a hope that it would have some effect in kala-azar, but hardly a prediction of its really remarkable efficacy in that previously intractable form of infection. Still less would it have justified expectation of the brilliant success of this same drug in infections by the Schistosoma or Bilharzia-worm, which but recently seemed almost beyond the hope of any kind of treatment. With such instances in mind, one might, but a year or two ago, have been tempted to suggest that the attempts at theoretical investigation, of the intimate mechanism of the chemotherapeutic process, had contributed little to the practical achievements, and that a reasonably intelligent empiricism was still the safest guide. I do not think that the suggestion would even then have been defensible, and it would assuredly have been stultified by the results of the past few years. Patient, systematic exploration, by routes of which the initial sections were already mapped in the early days of chemotherapy, has in these recent years again led to results of major importance, both for practical therapeutics and for the theoretical basis of future advance. That the original theoretical framework begins to show itself inadequate for the expanding fabric is good reason for its reconstruction; but we may well beware of hasty and wholesale rejection, remembering that it served the early builders well. I think that it is especially encouraging to note that, though, in the action of almost every remedy which has proved its value in the specific cure of infection, there are features which cannot be interpreted by a strict application of Ehrlich's distribution hypothesis, the discrepancies begin to show a new congruity among themselves. Repeatedly we find phenomena which point to the need of modifying the theoretical structure in the same direction. The conception of a remedy not killing the parasites immediately, but modifying their virulence, or lowering their resistance to the body's natural defences; of a remedy not acting as such, but in virtue of the formation from it in the body of some directly toxic product, either by a modification of its structure or by its union with some tissue constituent; of an affinity of the remedy for certain cells of the host's body, leading to the formation of a depot from which, in long persistent, never dangerous concentration, the curative substance is slowly released; all these conceptions present themselves, again and again, as necessary for our present rationalisation of the effects observed. It can hardly be doubted that they will potently influence the methods by which, in the immediate future, new and still better specific remedies are sought. But though our practical aim, in relation to the affinities of a remedy for the parasite and for the host's tissues, may be radically changed, the meaning of these specific affinities, so delicately adjusted to a precise molecular pattern, remains dark. Ehrlich's chemoreceptors may no longer satisfy us, but we have nothing equally definite to replace them. I have endeavoured to indicate what seem to me hopeful signs of new contacts between biochemistry and chemotherapy. There is promise, in another direction, that at least some aspects of the problem

of immune specificity are being brought within the scope of strictly chemical investigation, as in the recent work of Avery and Heidelberger, on the constituent of a pneumococcus which combines with the specific precipitin. As in Ehrlich's pioneer work in chemotherapy, it can hardly be doubted that an increased understanding of the meaning of immune specificity, which but a short while ago might have seemed hopelessly beyond the range of attack by chemical weapons, will still influence ideas, and help to shape the course of further investigations, on the chemotherapeutic process. As the biological complexity of the problem is realised, it becomes increasingly a matter for wonder and admiration that so much of practical value has already been achieved —the treatment of the spirochætal infections, syphilis, yaws and relapsing fever, revolutionised; Leishmania infections, kala-azar and Baghdad boil, and Bilharzia infections, which crippled the health of whole populations in countries such as Eygpt, now made definitely curable; trypanosome infections, such as the deadly African sleeping-sickness, after years of alternating promise and disappointment, brought now at last within the range of effective treatment. And if such results have already been attained, in a period during which practice has often and inevitably outrun theory, we may well be hopeful for a future, in which fuller understanding should make for more orderly progress.

FORTHCOMING EVENTS

Oct. 1. SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS, in the Chemical Society's Rooms, Burlington House, Piccadilly, London, W. 1, at 8 p.m.

The following papers will be read:—"The Determination of Coconut Oil and Butter Fat in Margarine," by G. D. Elsdon and P. Smith. "A Preliminary Note on the Composition of the Fat of Goat's Butter," by F. Knowles and J. C. Urquhart. "The Quantitative Estimation of the Degree of Hydrolysis of Gallotannin by Tannase," by Miss W. N. Nicholson and D. Rhind. "The Pemberton-Neumann Method for the Estimation of Phosphorus," by Miss M. B. Richards and W. Godden. "Application of 'Formal Titration' to the Kjeldahl Method of Estimating Nitrogen," by W. S. Shaw. Informal Dinner will be held for Members and their friends at St. James' Restaurant, 178 Piccadilly, at 6.30 p.m.

Oct. 2. SOCIETY OF CHEMICAL INDUSTRY, *Bristol Section*, the Chemical Department of the University (Woodland Road), Bristol, at 7.30 p.m. "Combustion Control in Boiler Houses," by H. T. Ringrose.

WORK has begun on the construction of a plant for the manufacture of pulp from straw, to the north of Selkirk, Manitoba. M. Dolphus, representing the De Vains interests in Great Britain, has completed arrangements, and W. R. Allan, president of the Union Bank of Canada, will be on the directorate.

SOCIETY OF CHEMICAL INDUSTRY

CHEMICAL INDUSTRY DINNER

The Autumn Dinner, which will be under the auspices of the Society of Chemical Industry and the Chemical Industry Club, will be held in the Edward VII Rooms of the Hotel Victoria, Northumberland Avenue, London, W.C. 2, on Friday, November 14, at 7 for 7.30 p.m., and will be presided over by Mr. W. J. U. Woolcock, C.B.E., President of the Society.

A circular letter with further particulars and a form of application for tickets has been sent out to the members.

BACK NUMBERS OF JOURNAL

The General Secretary will be glad to hear from Members or Subscribers who have copies of the *Journal* for January 5, 1923, or January 4, 1924, that they are willing to dispose of to the Society.

OTTAWA SECTION

On September 4 a joint meeting was held with the Ottawa Branch of the Engineering Institute of Canada, Dr. A. E. Macintyre in the chair.

In opening the meeting the chairman exhibited a map prepared by the natural resources and intelligence branch of the Department of the Interior, which showed the production, importation and consumption of coal in the various provinces of Canada.

Prof. W. A. Bone, F.R.S., then read a paper on "The Brown Coals and Lignites of the British Empire. Why Coals Coke." Prof. Bone expressed his great appreciation of the hospitality extended to the British Association during the Canadian visit and hoped that the visit would strengthen the bonds of unity within the Empire. Co-operation was necessary in all parts of the Empire in order that the great natural resources in brown coals and lignites might be exploited to the best advantage. The coalfields from Saskatchewan to the Rockies were unique and appeared to have been laid late in the earth's history. There was a gradual maturing of the coal from Saskatchewan westward. This field, perhaps, offered the best opportunity for chemists to determine how coals were formed, and it would be of great value if Canada would so investigate it.

An outline was then given of coal formation and after this the scheme was described for developing electric power at the Morwell brown-coalfields in Australia, where the coal is burned in water tube boiler furnaces after being dried with the waste gases. The drying increased the rates of combustion and of evaporation more than threefold. The heat units might be concentrated with advantage by heating to 375° C. The Saskatchewan lignites were heated to 350° C. to increase their burning efficiency in his experiments with them. The yield of coal tar in the low temperature carbonisation of these coals was generally below 4 per cent., so they could not be considered a source of oily hydrocarbons.

The thanks of the meeting was expressed by Mr. F. J. Hambly for the chemists and Mr. J. L. Rannie for the engineers.

CORRESPONDENCE

CHEMICAL AND PHYSICAL UNITS

Sir,—Some little time ago I resigned my membership of the Joint Committee for the Standardisation of Scientific Glassware, so I may be permitted to criticise their report.

Their resolution to the effect that "volumetric glassware *shall be graduated* in terms of "the millilitre, involves metaphysical rather than physical considerations. They do not make it sufficiently clear that the difference involves an error of the order of 1 part in 35,000, which is far outside the limit of error of manufacture, and indeed, no ordinary laboratory would have the means of determining whether an article should really be marked c.c. or ml. What the Committee really has done is to show the weakness of the suggestion put forward by another representative committee of chemists to the effect that the Mohr unit should be adopted as the basis of standardisation of chemical glassware. The N.P.L. could well have dealt with this suggestion without the aid of a second committee.

While referring to units it is an extraordinary fact that a very large number of chemists consistently refer to "normal pressure" as being represented, in London, by 760 millimetres of mercury. As a matter of fact the international unit refers to sea level in Lat. 45, which is equivalent to 759·55 millimetres in London. It is upon this basis that we reckon the mass of a litre of oxygen at 1·4290 grams. Taking the normal pressure at 760 millimetres an error of 1 in 1700 is involved. It is not of much use reading a barometer to 0·1 mm., applying a correction for temperature reckoned to be of the same order of accuracy, and then neglecting the gravity correction of about half a millimetre.

In technical work standard pressure is often taken to be 30 in. of mercury at 0° C. This is equivalent to 762·98 millimetres. This involves a departure of about 1 in 300 from normal pressure, but the difference is often ignored.—I am, Sir, etc.,

M. W. TRAVERS

London, E.C. 4

THE EARLY HISTORY OF CHEMICAL INDUSTRY

Sir,—According to Parkes, a workman who had absconded from Roebuck's employ started a works for the manufacture of sulphuric acid at Bridgenorth (Salop) in 1736. The writer will be grateful for any confirmation of this statement, and further particulars, if known.

Roebuck's works are stated by Prosser to have been in Steelhouse Lane, Birmingham. They eventually passed into the hands of Messrs. Alston and Armitage, and were continued under the name of Alston and Sons down to the year 1825, or perhaps later. Presumably these were the works at which the first leaden vitriol chamber was erected. It would be of great interest to hear if any drawings or other illustrations of early chemical works or plant are in existence at the present date, or indeed, portraits of some of the early pioneers of chemical manufacture. The following names of those who have shared in laying foundations of the heavy chemical industry, occur to me at random—Drebbel, Ward, Dossie, La Follie, Roebuck, Garbett, Holker, Clement, Desormes, Gay Lussac, Glover. The list could doubtless be considerably extended. Illustrations of early chemical plant, the result of their efforts would form an interesting series of considerable historical value.—I am, Sir, etc.,

H. A. AUDEN

120, Whitehedge Road
Garston
September 13, 1924

PERSONAL AND OTHER ITEMS

His Royal Highness Prince Arthur of Connaught has graciously consented to undertake in November the formal opening of the Ramsay Laboratory of Chemical Engineering at University College, instituted in 1923 as part of the Memorial to the late Sir William Ramsay, K.C.B., F.R.S. A full course of study in chemical engineering will be provided in the laboratory in the coming session, leading to the degrees of M.Sc. or Ph.D. in Chemical Engineering. The Course is designed to meet the demands of the manufacturing industries for men trained in the application of scientific methods to the design and operation of industrial chemical processes and plant. Special facilities are provided for research.

Mr. W. J. U. Woolcock, C.B.E., president of the Society of Chemical Industry, has been elected an Honorary Member of the Chemical, Metallurgical and Mining Society of South Africa, for the year ending June 30, 1925.

During the recent autumn meeting of the Institute of Metals, Prof. T. Turner, the president, announced that £1600 had been given anonymously to the endowment fund of the Institute.

Dr. J. S. Haldane has succeeded Sir John Cadman as president of the Institution of Mining Engineers.

The Ministry of Agriculture announces that the Government has decided to provide a further sum of £500,000 for agricultural education and research, in addition to the funds available for the same object amounting to £1,000,000 under the Corn Production Acts (Repeal) Act, and about £400,000 a year from other Government funds.

The following awards for the year 1924-25 have been made by the Salters' Institute of Industrial Chemistry and approved by the Court of the Company: Fellowships are renewed to Dr. W. G. Sedgwick, Armstrong College, Newcastle-on-Tyne, and Oxford, Fellow, 1923-24, and to Mr. W. Randerson, Imperial College of Science and Technology, Fellow, 1922-23, and Hon. Fellow, 1923-24 (during tenure of Albert Kahn Travelling Fellowship). Fellowships are awarded to Mr. H. H. Evers, University of Liverpool; Mr. K. Knight Law, University College, Nottingham; Mr. H. S. Pink, University College, Nottingham, and Oxford; and Mr. V. E. Yarsley, Birmingham University. The Salters' Institute has also awarded 72 Grants in Aid to young men and women employed in chemical works in and near London to facilitate their further studies.

We greatly regret to announce the death of Mr. Otto Hehner whilst on a visit to South Africa. An obituary notice of Mr. Hehner, who was an original member of the Society of Chemical Industry, will appear in a later issue.

The death is announced, at the age of 80, of Mr. John Allen, chairman of Frederick Allen & Sons, Ltd., chemical manufacturers, Poplar, and an original member of the Society of Chemical Industry.

Empire Motor Fuels

The report of the Empire Motor Fuels Committee set up by the Imperial Motor Transport Council has been published by the Institution of Automobile Engineers. The report constitutes a remarkably complete review of practically every motor fuel whether commercial or not, from the points of view both of chemical and physical properties and of efficiency in actual use. The possibilities of alcohol alone or in admixture with other fuels are shown to be very promising, and interesting results have been obtained in the prevention of "knocking" by adding very small amounts of pyridine, diethyl and tetraethyl compounds to the fuel. The results are given of tests with 90, 95 and 99 per cent. alcohol and with mixtures of alcohol and ether. The reports of sub-committees on denaturation and excise restrictions have been published separately.

Fur Dermatitis

The Ministry of Health has issued a report (Reports on Public Health and Medical Subjects, No. 27, pp. 31. H.M. Stationery Office, Price 9d.) of an enquiry into the occurrence of dermatitis attributed to the wearing of fur collars. Examination showed that the disease was caused by furs consisting of rabbit skins dyed to resemble beaver. The dyes used were found to be paraphenylenediamine and metaphenylenediamine, which have to be developed by oxidation, hydrogen peroxide being generally used. When oxidation is incomplete, owing to carelessness or from motives of economy, actively irritant bodies such as quinone di-imide are produced, and these products set up dermatitis. It is concluded that defective or careless technique in the use of potentially dangerous dyes is, in all probability, the cause of fur dermatitis.

"Antiknock" Compounds

It is well known that the presence of a minute quantity of tetraethyl lead in motor fuel will prevent knocking in internal-combustion engines, but no explanation has been given of the mechanism of this curious phenomenon. An explanation has, however, been suggested by G. L. Wendt and F. V. Grimm (*Ind. & Eng. Chem.*, Sept., 1924). According to these workers, the energy released in the reaction of the hydrocarbon with oxygen serves in part to liberate electrons from the reacting molecules, and the electrons, propelled at high velocity from the flame front, ionise the molecules in the gas in front of the flame, this ionisation being regarded as the cause of the acceleration of the flame. It is thus suggested that the function of the lead atoms in tetraethyl lead is to attract these electrons, and form highly-charged lead ions, thus preventing the ready ionisation of the unburned hydrocarbons. In addition, the lead, it is considered, will attract the positively charged hydrocarbon ions and thus render them momentarily inactive. Experiments made by the authors provide evidence in favour of their theory, and the work is being extended to other antiknock compounds.

Italian Mineral Production in 1923

The following table shows the output of the various minerals and their products in 1923 as compared with 1922 :—

	1922 Metric tons	1923 Metric tons
Mines—		
Iron ore	311,214	295,450
Ferromanganese	3,196	10,050
Manganese ore	4,694	9,190
Copper ore	7,863	7,230
Lead ore	30,617	36,804
Zinc ore	94,956	136,881
Antimonial ore	607	700
Iron pyrites	486,000	493,412
Anthracite	26,423	9,42[illegible]
Coal	168,929	159,50[illegible]
Lignite	745,402	938,22[illegible]
Bituminous schist	5,476	2,52[illegible]
Peat	56,687	56,1[illegible]0
Raw sulphur	167,339	248,[illegible]16
Ground sulphur ore	22,706	15,[illegible]00
Rock salt	49,802	53,[illegible]59
Medicinal salt	86,572	1[illegible]0,197
Petroleum	4,290	4,810
Asphalt and bituminous rock	67,895	140,250
Bauxite	66,646	98,222
Leucite	18,000	8,720
Boric acid	2,448	2,500
Graphite	4,546	5,584
Quarries—		
Pumice stone	21,036	30,000
Asbestos	540	1,510
Steatite and talc	26,485	31,140
Barytes	21,300	26,300
Coloured earths	6,505	10,000
Quartz and felspar	39,864	40,770
Porcelain clay	7,687	9,885
Magnesium earths	8,700	13,250
Refractory material	48,779	58,250
Silicious sand	216,540	241,000
Fluorspar	[illegible]	3,362
Metallurgical Industries—		
Pig iron	143,198	229,100
Synthetic pig iron	14,400	18,060
Steel and iron in ingots	981,419	1,121,912
Metallic alloys	20,214	28,180
Lead	10,709	17,059
Silver	6,367 kilos	9,536 kilos
Zinc	3,082	3,700
Zinc white	715	1,009
Copper cement	409	397
Antimony	209	175
Asphalt	41,920	38,400
Refined bitumen	993	900

In ferro-alloys, the production of which was insignificant before the war, considerable progress has been made. Steel production in 1923 was greater than it was before the war (933,500 tons in 1913), but less than the 1,331,641 t. recorded in 1917, the record year. The facilities of the Italian plants were greatly enlarged during the war and at the present rate of production it is estimated that they are working at only about two-thirds of their capacity. The production of metallic zinc in Italy is very small, most of the ore being exported to Belgium, France and Germany. The zinc industry

is new to Italy, and no production of metallic zinc is recorded for 1913, 1914 or 1915. Italy's zinc resources were materially increased during the war owing to the existence of important mines in the annexed Austrian territory. The production of metallic lead, although considerably greater, is still elow the pre-war average of 21,674 t. The present esources of copper are very limited, having declined rom 86,953 t. in 1914 to 7230 t. in 1923. No metallic opper was produced in 1922, but 150 t. was recorded or 1923. Imports of copper in 1923 were 46,983 t., of which 26,539 t. was supplied by the United States. In 1923, 1500 t. of nickel ore was mined, as compared with 22 t. during the previous year, but no production of metallic nickel is recorded. The output of bauxite in 1923 was approximately 50 per cent. greater than in 1922, whilst that of aluminium remained practically stationary around 800 t.

Practically the entire output of fuel consisted of lignite, although 159,500 t. of coal, which is actually a high-grade lignite produced in Istria, is also recorded. It is interesting to note that after having shown a decline from a maximum of 2,117,145 t. in 1918, the production of lignite is again increasing and reached 938,229 t. in 1923. The agreement between the Sicilian sulphur consortium and the American producers, concluded in March, 1923, resulted in a considerable increase in the Italian production of raw sulphur, but there was a small decline in the output of ground sulphur ore.—(*U.S. Com. Rep., May* 19, 1924.)

Shock resisting glass in Czechoslovakia

The Prague Glass Works, organised in 1919 with a share capital of 12,000,000 crowns, is engaged principally in the manufacture of laboratory glass and other special glass products, and has lately come to an agreement with the owners of the patent for the production of a shock-resisting glass under the trade name "Resista," whereby "Resista" glass shall be produced as soon as the plant can make the necessary technical preparations.

The World's Production of Fertilisers

In 1923 the output of ammonium sulphate was as follows:—France, 88,000 m.t.; Germany, 900,000 m.t.; United States, 420,000 m.t.; Britain, 360,000 m.t., and Japan, 70,000 m.t. In the same year, France produced 50,000 m.t. of cyanamide, Germany, 400,000 m.t., and Japan 40,000 m.t. Imports of Chilean nitrates into France amounted to 268,000 t. as compared with 322,000 t. in 1913. Notwithstanding the reduced output of natural phosphates elsewhere, Algeria, Tunis and Morocco steadily developed their production. In Northern Africa the progress of extraction has been as follows:—Algeria, 402,000 t. in 1921; 615,000 m.t. in 1923; Tunis, 1,418,000 m.t. in 1921, and 2,261,000 m.t. in 1923; Morocco, 80,000 m.t. in 1922, and 190,000 in 1923. Whilst the world's output of superphosphates decreased to 9,094,000 t. in 1923, against 12,222,000 t. in 1913, French production has increased from 1,979,000 m.t. in 1913 to 2,215,000 m.t. in 1923. The output of dephosphorising slags is decreasing, France producing 617,000 m.t. in 1913, and 585,000 in 1923; Luxembourg, 282,000 m.t. in 1913, and 235,000 in 1923; Germany, in 1913, 2,029,000, and 480,000 m.t. in 1923; and Belgium, 482,000 m.t. in 1913, as against 275,000 in 1923. The production of potassium salts has risen from 146,355 t. in 1921, to 230,000 t. in 1922, and 248,528 t. in 1923. Whereas 42,437 t. was imported in 1913, about 167,000 m.t. was exported in 1923, about 10,000 m.t. going to Great Britain.

COMPANY NEWS

UNITED INDIGO AND CHEMICAL CO., LTD.

The report for the year to June 30, 1924, shows a gross profit of £41,587, which includes excess profits duty previously reserved and was struck after providing an unstated amount for depreciation. General charges absorb £4669, leaving a net profit of £36,918. A further dividend is proposed on both the preference and ordinary shares, making 15 per cent. for the year (compared with 10 per cent. last year, and 12½ per cent. for 1921–22), carrying forward £11,262, against £9969 brought in.

BRITISH ALUMINIUM CO., LTD.

The directors announce a dividend at the rate of 5 per cent. per annum, less tax, on the ordinary shares for the six months ended June 30, 1924, payable October 1.

BURT, BOULTON, AND HAYWOOD, LTD.

Since the last report 92,000 ordinary shares have been issued, and also £300,000 6 per cent. first mortgage debenture stock. The latter will take the place of the Bank loan (for £244,000) appearing in the balance sheet. Net profits of £72,928 were earned in the year to June 30 last, after writing off £20,000 for depreciation. The balance of £10,163 brought forward is added. The preference dividends, the interim ordinary dividends, and distribution on the workers' certificates absorbed £16,908. A final dividend of 4 per cent. is proposed on the ordinary shares, making 8 per cent. free of tax for the year (the same as for the preceding twelve months), together with a final distribution of £302 on the workers' certificates. In addition £30,000 is to be carried to reserve, and there will be a balance of £17,241 to be carried forward.

LEYLAND AND BIRMINGHAM RUBBER CO.

Profits for the year ended June 30, 1924, amounted to £78,739, a decline of £5064 on the previous year's figure. Depreciation, reserve for discounts, bad and doubtful debts and directors' remuneration absorb £20,456 (against £19,332), leaving a net profit of £58,283, compared with £64,470. The directors recommend a final dividend of 7½ per cent. on the ordinary shares, again making 10 per cent., placing £5000 to the reserve account (against £7000), leaving £31,074 to be carried forward, compared with £30,791 brought in.

NEW TAMARUGAL NITRATE CO., LTD.

An interim dividend of 10 per cent. is announced on account of profits for the year to July 31 (the same as the interim dividend for 1922–23).

REPORTS

REPORT ON THE INDUSTRIES AND COMMERCE OF SPAIN. Dated March, 1924. By Capt. U. DE B. CHARLES, C.B.E., H.M. Commercial Secretary, Madrid. Department of Overseas Trade. Pp. 78. H.M. Stationery Office. 1924. Price 2s. 6d.

Little advance was made either commercially or industrially during 1923 (cf. *Chem. and Ind.*, 1923, 991). The two main problems are Morocco and transport, still awaiting solution. The most acute stage of the industrial crisis occurred in 1923, but is now considered to be past, and better results are hoped for during 1924.

In the mining and metallurgical industries the year opened with good prospects which were, however, not fulfilled. The protection given by the Conservative Government to the coal industry was much modified. The output from the Asturian mines was 2,500,000 t., and 1,500,000 t. of British coal were imported, the total consumption being 5,684,000 t. Owing to reduced British demands the output of iron ore was low. Exports of cupreous pyrites fell and price-cutting by the larger producers placed many small concerns in difficulties. The lead industry remained about the same, 64 183 t. being exported in 1923; the present high prices are leading to the opening of fresh workings. Zinc output was slightly improved, but that of mercury fell somewhat, though an improvement is hoped for this year. Cement production increased considerably in 1923, the output being estimated at 600,000 t.

Harvests in general were above the average, but prices fell owing to reduced purchases: the sugar crop was abundant.

The total value of imports in 1923 was 2708 million pesetas (nominally £1=25·22 pesetas, 1923 average about 32) against exports 1117 mill. pesetas. There were increased imports of oils, natural earths, phosphates of lime and window-glass, and decreased imports of coal, coke and briquettes, lime, cement, asbestos, tar and pitch, and glass other than window-glass. Among metals and manufactures of metals there was some change in the products in demand, steel in hoops and rough iron bars showing a big increase for example, whilst pig-iron imports fell considerably. The United Kingdom holds a fairly good position here with Belgium, Germany and the United States as the chief competitors. Among chemicals, dyestuffs are obtained but little from this country, which, however, holds the lead in oils, fats and waxes, glycerin, alkali borates, copper sulphate, ammonium sulphate and other ammonium salts, and cream of tartar. Among textile imports Great Britain has a strong competitor in France. The total imports from Great Britain in 1923 were valued at £11,333,512.

REPORT ON THE FINANCIAL, COMMERCIAL, AND INDUSTRIAL SITUATION OF AUSTRIA. Revised to July, 1924. By O. S. PHILPOTTS, O.B.E., H.M. Commercial Secretary, Vienna. Department of Overseas Trade. Pp. 50. H.M. Stationery Office, 1924. Price 1s. 6d.

The League of Nations scheme for the reconstruction of the country has met with much success, and the budget is due to balance by the end of this year. The improvement in national finance is not, however, reflected in the general economy of the country; a financial crisis in the spring of this year led to a number of failures. On the other hand unemployment has recently decreased. Politically, the country has been undisturbed and relations with neighbouring countries are excellent.

The agricultural industry still has far to go before reaching pre-war standard, though a steady improvement has been noticeable since 1919. Coal consumption in 1923 was again lower than in the previous year: unemployment in various industries offers some explanation, but the development of water-power is also beginning to make itself felt; the decrease, too, is mainly in lignite. There is strong competition between Czechoslovakia and Poland for the Austrian market in black coal; 72,000 tons of coal and 24,000 tons of coke were imported from Great Britain.

The country is highly industrialised and has a large surplus of manufactured goods for export. The industrial crisis which followed the stabilisation of the crown in 1922 lasted throughout 1923, but has diminished in intensity and unemployment has decreased considerably, largely owing to the occupation of the Ruhr and the collapse of Germany as a competitor. Production of pig-iron in Austria in 1923 amounted to 323,172 t. and of steel to 499,442 t.; the latter part of the year was the more favourable. The percentage of full production in February, 1924, was estimated as follows:—Leather 60, boots 50, rubber 100, cotton 75-80, wool rather higher than cotton, hemp and flax 60, knitted goods 66, glass 20. The stagnation of Austrian industries is likely to last some time, both on account of the loss of pre-war markets and also the high rates of transport.

In 1923 imports into Austria amounted to £77,122,000 against £73,220,000 in 1922, whilst exports were valued at £43,238,000, against £46,369,000. The rise in imports was mainly in articles of food and drink and in finished goods, rather than in materials and machinery for the improvement of industrial and agricultural production. The principal source of imports is Czechoslovakia, with 23·2 per cent. of the total in 1923, Germany coming next with 16·6 per cent., followed by Hungary with 11·4 per cent. The most important exports from Britain to Austria are leather, textiles, iron, and raw and semi-manufactured materials.

A HOT SPRING AT ARCACHON

This spring, which was mentioned by our special correspondent in his account of the Fourth Congress of Industrial Chemistry at Bordeaux, was discovered as the result of borings put down to 464 m. in the Abatille Forest by the Société de Recherches d'Hydrocarbures. The water, at a temperature of 25° C., springs 10 m. into the air, flowing at a rate of 60,000 m. per hour, and its radio-activity is similar to that of the mineral waters at Vichy. The water is alkaline, contains free carbonic acid, nitrogen and sulphide, and is slightly magnesium.

REVIEWS

The Action of the Beater. By Dr. S. Smith. Translated by Major R. Marx, M.C., B.Sc. Pp. xi+212. London: The Technical Section of the Papermakers' Association of Great Britain and Ireland, 1923. Price 15s.

The important part which the beater occupies in the manufacture of paper is well known, and the statement that "the sheet is made in the beater" is in many instances justified. Mr. C. F. Cross in the Foreword quite correctly describes the beater as the pivot of the mill, and the beating preparation of the fibrous raw material as *the* papermaking operation.

"The Action of the Beater" is a particularly valuable addition to the literature, because in it the author discusses the results of a very large number of systematic experiments which he has carried out under mill conditions.

In the introduction the author draws attention to the widely different views held by papermakers on the question of beating and of makers of beaters on their construction, and everyone will agree with him that "any reliable theory on the beating operation must be largely based on detailed investigation of all the factors concerned."

Both in the Introduction and in Chapter VI, "Comparative Beating Tests," the work carried out by previous investigators is fully, and in many cases, critically discussed.
